Authors of Volume 10

S. J. Aspinall
Freelance Ecological Consultant and writer, Abu Dhabi, United Arab Emirates.

Dr T. M. Blackburn
Reader in Macroecology, School of Biosciences, University of Birmingham, Birmingham, England.

Dr D. Brewer
Research Associate, Department of Ornithology, Royal Ontario Museum, Toronto, Canada.

Dr P. Cassey
Postdoctoral Researcher, School of Biosciences, University of Birmingham, Birmingham, England.

Dr M. C. Chu
Science Editor, Cornell Laboratory of Ornithology, Cornell University, Ithaca, New York, USA.

J. Clavell
Co-ordinator of the Exotic Birds Study Group (GAE), SEO/BirdLife, Barcelona, Spain.

Professor M. L. Cody
Emeritus and Research Professor, Department of Ecology and Evolutionary Biology, University of California, Los Angeles, California, USA.

Dr N. J. Collar
Leventis Fellow in Conservation Biology, Conservation Biology Group, Department of Zoology, University of Cambridge, Cambridge, England.

Professor R. P. Duncan
Associate Professor, Bio-Protection and Ecology Division, Lincoln University, Lincoln, Canterbury, New Zealand.

Dr L. D. C. Fishpool
BirdLife International, Cambridge, England.

Dr B. J. Hatchwell
Reader, Department of Animal & Plant Sciences, University of Sheffield, Sheffield, England.

Professor D. E. Kroodsma
Professor Emeritus, Department of Biology, University of Massachusetts, Amherst, Massachusetts, USA.

Dr D. J. Mountjoy
Assistant Professor, Department of Biology, Knox College, Galesburg, Illinois, USA.

Professor S. J. Ormerod
Professor of Ecology, School of Biosciences, Cardiff University, Cardiff, Wales.

R. F. Porter
Adviser to BirdLife International's Middle East Conservation Programme.

Dr D. Sol
Associate Researcher, Centre de Recerca Ecològica i Aplicacions Forestals (CREAF), Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.

Dr P. B. Taylor
Honorary Research Associate, School of Botany & Zoology, University of KwaZulu-Natal, Pietermaritzburg, KwaZulu-Natal, South Africa.

H. J. Temple
Postgraduate, Department of Zoology, University of Cambridge, Cambridge, England.

Dr J. A. Tobias
BirdLife International, Cambridge, England.

Dr S. J. Tyler
Monmouthshire, Wales.

Dr D. R. Wells
Research Affiliate, University Museum of Zoology, Cambridge, England; formerly University of Malaya, Kuala Lumpur, Malaysia.

Foreword

The Ecology and Impact of Non-indigenous Birds

1. Introduction

In March 1890, around 60–80 Common Starlings (*Sturnus vulgaris*) were released into Central Park, New York, as a plan to establish in North America all avian species cited in the works of Shakespeare (Wood 1924). Early attempts to introduce the species in 1872/73 had failed, but this one proved to be successful. Supplemented by subsequent introductions, the starlings spread to other states, reaching Pennsylvania in 1908, Alabama in 1918, and Kentucky in 1919. This range expansion continued during the following decades, and today the Common Starling is one of the most abundant and widespread birds in North America.

The introduction of plants and animals facilitated by human activities has been so common and widespread a phenomenon that alien species are currently recognized as a central element of global environmental change (Sakai *et al.* 2001). For birds alone, there have been more than 1900 documented attempts to introduce about 400 species all over the world (Cassey 2002a). A European visiting New Zealand, Australia or the Hawaiian Islands will likely feel at home listening to the familiar vocalizations of a variety of introduced European songbirds. Gerald Durrell (1966) noted on his trip to New Zealand: "We might as well have stayed at home if all we were going to see was blackbirds and skylarks".

This unprecedented exchange of species between regions is not only leading to a rapid homogenization of the earth's biota (Lockwood *et al.* 2000), but also poses a major threat to biodiversity and ecosystem functioning (Williamson 1996, Parker *et al.* 1999, Simberloff 2001, Fritts and Rodda 1998). Nowadays, non-indigenous species represent the second-most-frequent threat of species extinction after habitat loss, and they have become the primary threat to oceanic island biotas. Recent estimates indicate that one-quarter of all bird species at risk of extinction are threatened because of the effects of non-indigenous species (Stattersfield &Capper 2000). Non-indigenous species may affect native species through competition, predation or disease transmission; altering their genetics through hybridization and introgression; and can even change the structure and functioning of the entire ecosystem. In addition to ecological problems, invasive species are responsible for serious human health problems and important economic losses, which in the USA alone can exceed $100 billion per year (Vitousek *et al.* 1996, Everett 2000).

Given the considerable evidence currently available on the problems associated with past introductions, one would think that we would have learnt our lesson. Yet, surprisingly, potentially damaging introductions continue in many regions of the planet. In fact, many countries do not seem to perceive invasive species as an important problem. In a recent survey by the United Nations, fewer than 10% of the countries polled declared that most non-indigenous species in their territory had been identified, and only 2% acknowledged the problem enough to invest sufficient economic resources to deal with it.

What can we do to minimize the crisis generated by non-indigenous species? Given that once a species is established it is costly and often impossible to eradicate or control, prevention of new introductions is fundamental in order to minimize the impact of invaders (Mack *et al.* 2000). This demands that we understand the factors that allow certain species to establish and spread into foreign environments, so that we can identify situations where invasion risk is high (Duncan *et al.* 2003). Ecologists have long wondered what determines the success of species that are introduced into foreign environments (Mayr 1965, Ehrlich 1989). How is it that a species that has not evolved in a community not only is capable of invading it, but may even displace species adapted to live there through generations of selection?

Although researchers have for some time been pessimistic about the possibility of ever answering this question, recent studies have begun to uncover some of the rules that govern the invasion process (Williamson 1996, Kolar & Lodge 2001, Duncan *et al.* 2003). Much of this progress has come from the study of birds (Duncan *et al.* 2003, Cassey, Blackburn, Sol *et al.* 2004), for which detailed information is available on a large number of successful and failed introduction attempts (e.g. Long 1981, Lever 1987). Past avian introductions are undoubtedly an unfortunate natural experiment, but at the same time they have provided critical information for a better understanding of invasions and how we may prevent them. This has allowed the factors associated with their success and failure to be explored. Here, we describe the progress that has been made on this issue thanks to the study of avian introductions. We then examine the ecological and economic impact caused by avian invaders, and explore ways in which we might help mitigate the problem in the future.

2. A framework for understanding invasions

The process by which species establish exotic populations can be usefully illustrated as a sequence of stages (Figure 1; cf. Williamson 1996, Richardson *et al.* 2000, Daehler 2001, Kolar & Lodge 2001). First, the species must be transported from its native range to a new location. Second, it must be released or escape into that environment. Third, it must succeed in establishing a self-sustaining wild population, following release. Fourth, species that establish successfully may increase in abundance and spread beyond the release point, the extent of which defines their geographical range in the new environment. We term these stages transport, introduction, establishment and spread (see also Lockwood 1999, Kolar & Lodge 2001, Sakai *et al.* 2001), and for a species to have reached a given stage in the invasion process, it must have passed through all the previous stages (see Cassey, Blackburn, Jones & Lockwood 2004, Cassey, Blackburn, Russell *et al.* 2004, for analysis of transitions through these stages).

It is useful at this point to clarify some of the terms we will use. An introduced species is one that passes through the first two stages and is released (or escapes) into a new environment. An established (also termed naturalized) species is one that forms a self-sustaining wild population following introduction. An established species that succeeds in spreading beyond the site of introduction is termed an invasive, while the introduction of a species to a location is termed an introduction event. We use the term 'introduction' to refer to a species that has been transported to, and been released or escaped into, an alien environment, regardless of whether or not it establishes or spreads.

The stages shown in Figure 1 provide a useful framework for reviewing what we know about the factors affecting the outcome of bird introductions around the world, and we consider each of these stages in turn.

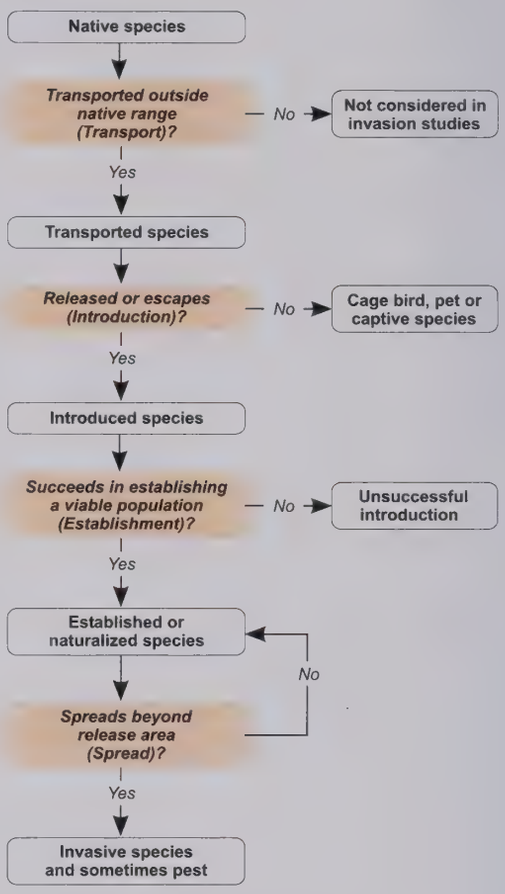

Figure 1. Schematic representation of the transitions in the process of a human-caused invasion that we recognize in this review. The stages through which a species must pass are shown in bold. From Duncan et al. *(2003).*

3. Transport and introduction

a. History of avian introductions

Since humans began purposefully leaving their homelands to colonize new territories, they have taken or brought back with them exotic plants and animals. Evidence for bird introductions dates back at least 3000 years in India, for introductions of the Greylag Goose (*Anser anser*), Rock Dove (*Columba livia*), and Red Junglefowl (*Gallus gallus*) (Cassey 2002a, Brooke & Birkhead 1991), and for introductions of junglefowl by Polynesian seafarers to locations as remote as Easter Island (Hurles *et al.* 2003).

Nevertheless, most bird introductions occurred during the great migrations of European settlers in the 18th and 19th centuries. The people moving to new colonies, notably in the Americas, Australia, New Zealand and South Africa, encountered new environments very different to the highly modified European landscapes they left behind. Introducing species that reminded them of their European homeland was one motivation for bird introductions, along with purposeful introductions for hunting and pest control; accidental escapes of cage birds were another cause. The process of transporting and introducing species was facilitated by the setting up of acclimatization societies in many countries during the 19th century. In New Zealand, for example, acclimatization societies were set up with a stated aim being "the introduction, acclimatisation and domestication of all animals, birds, fishes, and plants, whether useful or ornamental" (McDowall 1994). Private individuals also took it upon themselves to "improve" the biota of new territories through introductions (e.g. Guild 1938 on Tahiti) and in some cases even formed amateur naturalist groups (Long 1981). In

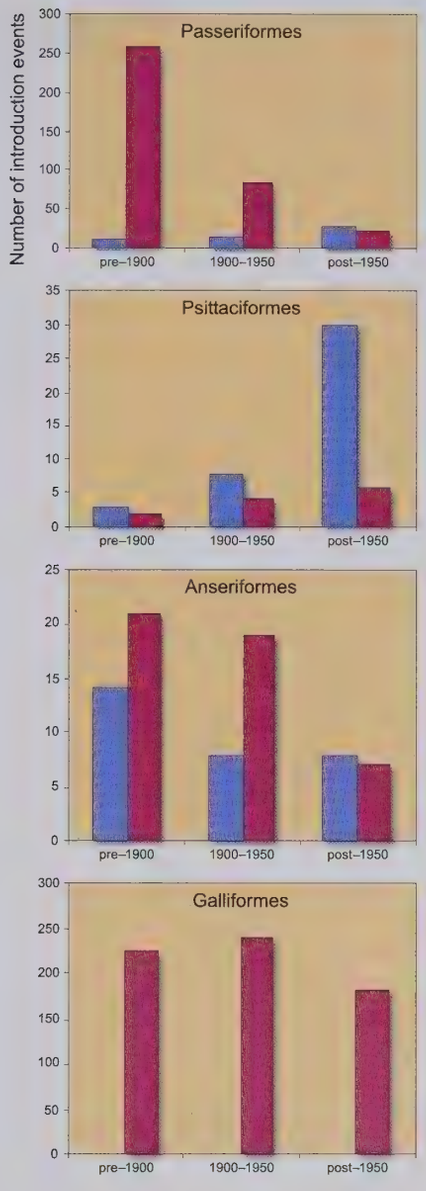

Figure 2. Trends in the frequency of accidental (blue bars) and deliberate (purple bars) introductions from early times to the present day, for four of the most widely introduced orders of birds.

South Africa, Cecil Rhodes introduced several species in order to diversify the bird fauna of Cape Town, described previously as "poverty-stricken" (Cassey 2002a).

Quite quickly, however, it was realized that bird introductions frequently had undesirable side-effects. By 1899 sparrows introduced to North America had been described as "one of the worst of feathered pests" (Palmer 1899), while in New Zealand Drummond (1906) commented that the "company [of the introduced birds] was found not to be half as desirable as had been anticipated". Indeed, in New Zealand the Protection of Certain Animals Act of 1861, which provided protection from hunting during most of the year for "swan, partridge, English plover, rook, starling, thrush and blackbird", was soon replaced by the Small Birds Nuisance Act of 1882, and eventually by The Injurious Birds Act of 1908, with provision for the wholesale destruction of certain introduced species (Thompson 1922). Growing awareness of the negative impacts of introduced birds has led to a decline in the frequency of purposeful introductions, particularly among Passeriformes, where early introductions (before 1900) were almost all intentional (Figure 2). Intentional introductions of Galliformes have continued, primarily for game purposes, while accidental introductions of Psittaciformes have increased, almost certainly in response to an increase in the importation and trade of cage birds.

b. Which species were selected for introduction?

Humans have transported and introduced to a new location fewer than 5% of the world's bird species (Blackburn & Duncan 2001a). The species chosen for transport and introduction are by no means a random subset of the world's birds. Instead they tend to be concentrated in certain taxonomic groups and geographical regions, and to possess particular characteristics. We examine the patterns and causes of selectivity for each of these features in turn.

Taxonomic selectivity

Three studies have examined the patterns of taxonomic selectivity associated with bird introductions worldwide. Blackburn & Duncan (2001a) considered selectivity in the birds chosen for introduction, while Lockwood (1999) and Lockwood *et al.* (2000) considered selectivity in the birds that had become established following introduction. The results are similar in that the families over-represented at the introduction stage are also the families over-represented among established species. Consequently, we can infer that a major cause of taxonomic selectivity among established species is taxonomic selectivity in the species chosen for introduction.

Of the species chosen for introduction, around two-thirds belong to just six bird families: Anatidae; Phasianidae; Columbidae; Psittacidae; Passeridae; and Fringillidae (Blackburn & Duncan 2001a). The over-representation of species in these families undoubtedly reflect two of the major motivations behind bird introductions: species in the families Anatidae and Phasianidae were primarily introduced for hunting; while species in the families Psittacidae, Passeridae and Fringillidae are frequently kept as cage birds and would have been transported and introduced by people for aesthetic reasons (see Long 1981, Lever 1987). Nevertheless, even introductions in these families involve only a small subset of species, and most (69–94%) of the species in these families have never been introduced by people outside their native range (Blackburn & Duncan 2001a).

Geographical selectivity

The number of bird species increases towards the equator. However, a disproportionate number of the bird species chosen for introduction come from temperate regions, with their native ranges centred between 30° and 50° in both hemispheres (Blackburn & Duncan 2001a). While the Neotropics are a centre of bird diversity, being home to around 30% of all bird species (Rahbek 1997), only about 8% of introductions involve species from this region. Conversly, about 16% of introductions involve species from the Palearctic, despite only about 10% of bird species having geographical ranges that include this region (Sibley & Monroe 1990). Overall, species from tropical regions are greatly under-represented in lists of introduced species.

This pattern of geographical selectivity can largely be attributed to introductions carried out by European settlers, who mostly colonized other temperate parts of the world. Thus, opportunities for the transport and trade of birds during the 18th and 19th centuries would have been greatest between western Europe and the predominantly temperate locations where Europeans settled and with which they traded, including North America, South Africa, Australia and New Zealand. Around 60% of the bird species introduced to New Zealand originate from the Palearctic and Australasian

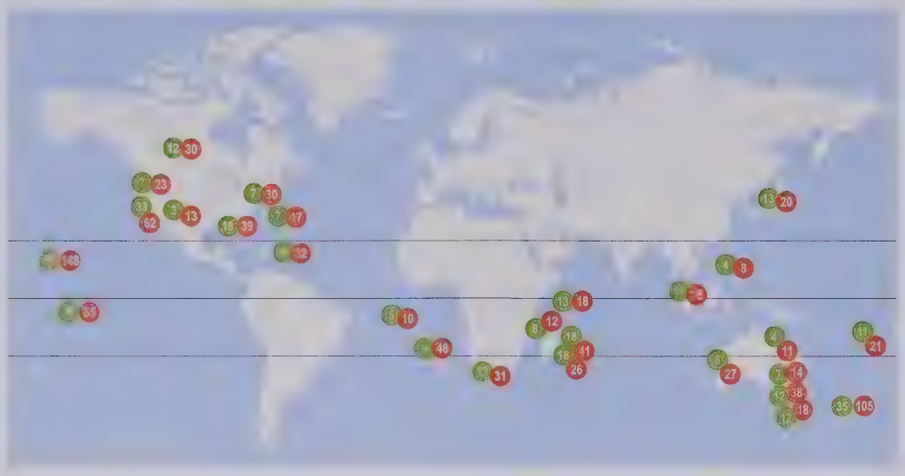

Figure 3. Regions of the world with highest numbers of established and introduced bird species.

Country, island or state of introduction	Established	Total introduced
Hawaiian Islands	58	148

regions (Duncan *et al.* 2005), the two areas with which trade and transport were most frequent during early European settlement of New Zealand.

Character selectivity

Birds in different taxa and from different regions of the world often possess characteristic life-history or ecological traits (e.g. Gaston & Blackburn 2000, Cardillo 2002). Given that the birds chosen for introduction are not a random subset of the world's birds, we might expect them to possess traits characteristic of the taxa or regions that are over-represented. Thus, we would expect introduced birds to possess predominantly the characteristics of temperate gamebirds (Anatidae and Phasianidae) or cage birds (Psittacidae, Fringillidae and Passeridae). There have been few tests of character selectivity for introduced birds, although for those introduced to Australia a high proportion of species are ground-nesters that utilize grassland, cultivation or suburban habitats, and have largely vegetarian diets, such as seeds, fruit and the like (Newsome & Noble 1986). Introduced species are also larger-bodied, on average, than would be expected if they were a randomly chosen subset of bird species (Blackburn & Gaston 1994, Cassey 2001a).

Selection for certain characteristics also occurs independently of taxonomic and geographical selectivity. Within both a geographical subset (e.g. species in the British avifauna) and a taxonomic subset (e.g. order Anseriformes: wildfowl) of the world's birds, the species chosen for introduction are those with larger population sizes (Blackburn & Duncan 2001a). For wildfowl, people tended also to select larger-bodied species, while for British birds they tended to select widely distributed and resident species. Species with a large population size, wide distribution and that are resident throughout the year are the commonest species, and hence the most readily available for capture and transport to new locations. They are also likely to be familiar species, and people may have targeted them specially for introduction.

Taken together, these findings describe a general hierarchy of causes that have contributed to the selective introduction of certain birds. First, the species chosen for introduction were concentrated in geographical regions that in large part reflect the origin of European settlers and their subsequent patterns of settlement and trade. Second, from within geographical regions, people chose certain kinds of bird for introduction for a variety of reasons. An emphasis on birds for hunting and aesthetic purposes has resulted in birds from five families being significantly over-represented among those chosen. Finally, given that birds were chosen for particular purposes and from certain regions, the species that were finally caught, transported and introduced tended to be those that were common in the source locations. People preferentially selected abundant, widely distributed species, either because they were most readily available for capture, or because they were species with which they were most familiar, and therefore most desired to introduce.

c. To which locations were birds introduced?

While birds have been introduced to all major regions of the world (Fig. 3), relatively few introductions have been to equatorial regions. Most have been to latitudes between 10° and 40° on both sides of the equator (Blackburn & Duncan 2001a). An additional, and very striking pattern, is that people mostly introduced birds to islands

(Cassey 2003). Around 70% of introductions have been to islands (Blackburn & Duncan 2001a) even though islands only make up about 3% of ice-free land area (Mielke 1989). Over half of all introductions were to islands in the Pacific (especially the Hawaiian Islands) and Australasia.

It is interesting to speculate why islands have been such a major focus for bird introductions. The answer may lie in the characteristically low numbers of bird species found on islands, relative to continents, and the extent to which island birds have suffered extinctions since human arrival. Only 52 bird species are recorded as being introduced to mainland Australia (Duncan *et al.* 2001), with its large and diverse native avifauna, compared with the introduction of over 120 species to nearby New Zealand (Duncan *et al.* 2004), with its smaller and less diverse avifauna that suffered a major extinction event following European arrival. With fewer species, European colonists may have perceived island avifaunas as being particularly impoverished and in need of "improvement".

4. What determines establishment success?

Once a species has been successfully transported and introduced, and thus passed through the first two steps on the introduction pathway, it finds itself at liberty in a novel environment. The next challenge it must overcome is to establish a self-sustaining population. The historical record shows that the chances of this are roughly 50:50 (Cassey 2002b). The obvious question then is what is it that distinguishes those cases that result in successful establishment from those that end in failure? Producing an answer to this question is complicated by the range of factors that could potentially influence establishment success.

For example, success may be more likely for species with high reproductive rates, which can rapidly build up populations to levels beyond which extinction is unlikely. Such species are typically small-bodied and short-lived. Alternatively, large body size and longevity may buffer a species against environmental fluctuations that could rapidly extirpate populations of less robust exotics. Clearly, the environment itself may also play an important role, with more stable and benign climates being perhaps more accommodating to introductions. Such climates may also have more stable and abundant food resources for the introduced species to exploit. However, in many cases they are also likely to house more potential competitors for those resources, and more predators ready to exploit the introduced forms themselves. Success in the face of these interactions could depend on how adaptable and flexible individuals of the exotic species are, and hence on their intelligence or capacity to innovate. Any of these factors could also be affected by the circumstances of each separate introduction. If only a few individuals were released (or mainly males), in poor condition (perhaps after a long sea journey from their homeland), or at a disadvantageous time of year, then any advantages bestowed by features of a species' biology or the location of introduction may count for little. On the other hand, carefully planned and supported introductions might succeed regardless. Thus, the idiosyncrasies of individual introduction events could mask the influence of other factors in determining establishment success.

This last point highlights a significant problem in any attempt to untangle the factors influencing the establishment of exotic species. As if the number of such factors were not enough, there is good reason to believe that many effects will be confounded, making the influence of individual characteristics harder to elucidate. For example, species that are commoner in Britain tended to be introduced in greater numbers to New Zealand (Blackburn & Duncan 2001a). Species that are common in Britain also possess traits that distinguish them from less common species—they tend to be passerines, small-bodied, and preferentially use certain types of niche (Nee *et al.* 1991, Gregory & Gaston 2000). It follows that for species introduced from Britain, characteristics of the introduced species will be confounded by the number of individuals introduced. If success is related to one of these factors, it is likely to be related to both. Separating the influence of confounded factors requires careful statistical analysis (using multivariate techniques).

Unfortunately, the issue of confounded factors is not the only significant problem that impedes the analysis of establishment success. The reader will recall that some species such as the House Sparrow (*Passer domesticus*) have been introduced to many exotic locations, while some locations such as Hawaii have received many exotic introductions. If some species are better at establishing than others, or if it is easier to establish at some locations than others, then the outcome of introductions of the same species, or of introductions to the same location, will be correlated. This means that each introduction event is unlikely to represent an independent piece of evidence for the influence of a factor on establishment success, because we would expect similar outcomes (either success or failure) for all species introduced to the same location, or

for all introductions of the same species regardless of location. This violates a core assumption of standard statistical tests, which assume that every data point analysed provides an independent piece of information for the test. When data points are not independent, statistical tests are more likely to show that factors are a significant influence on establishment success when actually they are not.

Let us consider, for example, bird introductions to Hawaii and New Zealand. A total of 142 bird species were introduced to the Hawaiian Islands (Moulton *et al.* 2001), where 56% of introduction events succeeded in establishing viable populations; in turn, 120 species were introduced to New Zealand and associated islands (Duncan *et al.* 2005), where only 35% of introduction events succeeded. It would be easy to conclude that tropical islands are easier to invade than temperate islands, and that we have over 200 independent data points (introduction events) to support this view. In fact, this is akin to concluding that women are taller than men by only comparing adult Swedish women and adult Pygmy men. We only really have two independent data points (the archipelagos), which is certainly not enough from which to draw any firm conclusions. The best we can do is conclude that it has been easier for birds to establish in the Hawaiian Islands than in New Zealand, which may be because of their different latitudes, but could result from any of the many other differences between them. Indeed, even that conclusion could be erroneous: instead, the species introduced to Hawaii might simply be better invaders than those introduced to New Zealand, or introduced in larger numbers, and so on. If we wanted to draw conclusions about establishment success in tropical versus temperate regions, we would have to bolster our data with introductions to other regions. Even then, if the majority of tropical introductions were to the Hawaiian Islands, these data might tell us more about Hawaii specifically than the tropics generally. In practice, therefore, we would also need to employ statistical techniques that can allow for confounding variables and incorporate information on non-independence, and so produce unbiased estimates of the effects of different factors; examples include generalized least squares, linear mixed models, generalized linear mixed models, and generalized estimating equations (Diggle *et al.* 1994, Goldstein 1995). Such techniques are only now being applied to the analysis of establishment success in birds (e.g. Blackburn & Duncan 2001b, Cassey, Blackburn, Sol *et al.* 2004).

Problems such as those just described with historical data have led some to conclude that establishment success is likely to be inherently unpredictable (Ehrlich 1989, Gilpin 1990, Williamson 1996). Indeed, early studies showed a notable lack of success in identifying any consistent patterns in establishment (Williamson 1996). Nevertheless, major goals of invasion ecology are to identify factors that have some potential for explaining the outcome of introduction events, and to identify which are most important and why (Williamson 1999). Despite their inherent problems, historical data on birds represent probably the best opportunity for understanding establishment processes for real introductions. That said, the problems described above mean that the results of many earlier studies must be treated with caution (Duncan *et al.* 2003). This needs to be kept in mind through what follows.

In order to make it easier to navigate through the tangle of factors that might potentially affect establishment success, we classify each factor into one of three categories: characteristics of the species introduced, such as their population growth rate or body size; features of the introduction location, such as its climate; and factors associated with, and often unique to, each introduction event, such as the number of individuals released. These are termed species-, location- and event-level factors respectively (Blackburn & Duncan 2001a; cf. Williamson 1999, 2001). The characteristics of each species and location ought to remain reasonably constant for all introductions concerning them. On the other hand, event-level characteristics seem very likely to vary idiosyncratically from one event to the next. Since the outcome of introduction events also seems to be idiosyncratic, this has led some authorities to conclude that event-level factors may be the key determinants of success (e.g. Williamson 1996, Duncan *et al.* 2003). Hence, it is with these that we begin our review of the causes of establishment success. In what follows, we review the findings of the wide range of studies that have explored the factors in each category thought most likely to be determining establishment success. We finish by synthesizing these findings to highlight what we think these studies really tell us.

a. The idiosyncrasies of individual introductions: event-level effects

Introduction effort

Most exotic species are released in low numbers and so start with small founding populations. Indeed, 49% of bird introductions for which the appropriate information

exists involved the release of fewer than 50 individuals (Cassey, Blackburn, Sol *et al.* 2004). IUCN categorize bird species with fewer than 50 individuals left in the wild as Critically Endangered, or Critical. In quantitative terms, this means that they have more than a 50% chance of becoming extinct in the next 10 years (or three generations), even if their populations are not currently in decline (Stattersfield & Capper 2000). These are species living in their native environment, to which they have presumably had plenty of time to become well adapted. Their small populations are highly prone to extinction for a variety of reasons, including the effects of environmental fluctuations (e.g. successive harsh winters or long periods of drought), natural disasters (e.g. hurricanes or volcanic eruptions), demographic stochasticity (random variations in the sex ratio of offspring can leave a population with few females), genetic stochasticity (reduced genetic variation can lower a population's adaptability, or increase the chances of inbreeding depression) and problems in finding mates at low densities. The probability of extinction for an equivalent-sized population of an exotic species that must additionally face the challenges of a new environment is presumably higher still. It is not surprising therefore that many introductions fail.

A straightforward explanation for the success of some introductions is that they involved the release of a greater number of individuals and so were more likely to escape the threats facing small founding populations. That is, establishment success increases with greater introduction effort (Cassey, Blackburn, Sol *et al.* 2004), or "propagule pressure" (Williamson 1996). Because information on release sizes has been recorded in many cases, it is possible to use historical bird introductions to test this hypothesis. All studies that have addressed this question so far have shown that species introduced with greater effort (typically measured as the total number of individuals released) have a higher probability of establishment (e.g. Dawson 1984 cited in Williamson 1996; Newsome & Noble 1986, Pimm 1991, Duncan 1997, Green 1997, Cassey, Blackburn, Sol *et al.* 2004). The same is true for re-introductions (Griffith *et al.* 1989, Wolf *et al.* 1998). Most studies show that greater introduction effort increases establishment success without specifically addressing the mechanism by which this increase is brought about, although Legendre *et al.* (1999) present evidence from birds introduced to New Zealand that it is at least in part due to a reduction in the effect of demographic stochasticity.

Introduction effort may influence establishment success not only through the number of individuals released, but also through the number of release attempts. A greater number of separate releases may improve the chances that at least some individuals encounter favourable conditions for population growth, while if different releases are from different locations, the probability that favourable habitat is encountered will also be increased (Crawley 1986). Veltman *et al.* (1996) reported that species successfully introduced to New Zealand were released at more localities than unsuccessful species, which supports the latter idea, although the number of localities and the total number of individuals released were correlated in their data. Griffith *et al.* (1989) found that re-introductions involving releases over a greater number of years had a greater probability of establishing, independent of the number of individuals released. This supports the suggestion that multiple releases are more likely to encounter favourable conditions for growth, because, unlike introductions, re-introductions are likely to be made into suitable habitat.

There are notable exceptions to the general pattern that greater effort leads to greater establishment success. Despite the introduction of over half a million Common Quail (*Coturnix coturnix*) to more than 30 states in North America between 1875 and 1958 (Bump 1970), no introduction succeeded (Lever 1987). Clearly, factors other than effort can determine the fate of introductions.

Environmental matching

We have mentioned that the survival probability of a small population of an exotic species is likely to be reduced by the additional challenges posed by a novel environment. It follows that the survival probability ought to be higher if a species is not so challenged because the climate and physical environment at the location of introduction matches that to which it is already adapted (Brown 1989, Williamson 1996). We classify environmental matching as an event-level factor here because it is a feature of neither the species nor the environment alone, but is defined by the interaction between the two. Two environmental matches will only be the same if they relate to two introductions of a given species to a given location, but as such multiple releases are defined as a single event, the environmental match is thus a feature unique to each introduction event.

A range of results supports the idea that a closer environmental match improves the chance that an exotic bird species will successfully establish. Regions at similar latitudes or within the same biogeographical region are more likely to be similar in

climatic and habitat conditions, and avian introductions are more likely to succeed when the difference between a species' latitude of origin and its latitude of introduction is small, and when species are introduced to locations within their native biogeographical region (Blackburn & Duncan 2001b, Cassey 2003). Success is also more likely when climatic conditions in the species' native range are similar to those of the introduction location (Duncan *et al.* 2001). Also supporting the importance of environmental matching is the finding that species re-introduced into the core of their original range had greater establishment success than species released in the periphery (Wolf *et al.* 1998). It is often argued that conditions at the core of a species' distribution will be more suitable for it than those at the edge (Brown 1984), although this is actually far from universally true (Gaston 2003).

Consistent with the importance of environmental matching is the finding that establishment success is often positively related to geographical range size across species (Moulton & Pimm 1986, Blackburn & Duncan 2001a, Duncan *et al.* 2001). Large geographical ranges typically span a wide range of environmental conditions, suggesting that the species that attain them may have broad environmental tolerances. Alternatively, wide-ranging species may utilize environments that are themselves widespread (Gaston 1994). Either way, wide-ranging species may be more likely to encounter suitable conditions following release at an exotic location, increasing their probability of establishment (for a related argument, see Ehrlich 1989).

The idea that a close match between the native and exotic environment may improve an introduced species' chances of establishing makes no assumptions about the quality of the environment itself. Yet, it seems intuitive that different environments ought to differ in terms of the ease with which exotic species can make themselves at home. Just as a life on a tropical island may seem more desirable to many people than one on a temperate island, might it not also seem so to introduced birds? Certainly, Hawaii is well stocked with them—over 70 species on recent estimates. Thus, we now go on to examine the evidence that some regions are more amenable than others to the establishment of exotic birds.

b. Why some regions house more exotics than others: location-level effects

Natural features

There are many features of the environment that might determine whether or not a location is hospitable for an exotic species, but these can be broadly divided into three groups (Shea & Chesson 2002, Duncan *et al.* 2003).

First, and what is probably most attractive to us about the Hawaiian Islands, the climate there might be relatively benign. Typically, we think of benign climates as those without extremes of temperature, humidity or rainfall. However, as we explored in the previous section, the definition of "extreme" will depend on the conditions to which each species is best adapted, and so there is unlikely to be any universal standard. Nevertheless, we do know that most bird species are located at warm tropical latitudes where water is plentiful, and that the number of species tends to decrease as annual minimum temperatures or water availability decrease (e.g. Whittaker *et al.* 2003). This suggests that, on average, climates at lower latitudes ought to be more benign for most species. Islands may also be more benign, as the maritime influence on their climate tends to moderate temperature extremes and ensures rain, at least to windward.

Second, establishment should be favoured at locations where there are more available resources. The specific requirements of species mean that, once again, there is unlikely to be any universal standard for resource availability. Moreover, it is a major task to quantify these requirements for even one species. Nevertheless, similar logic to that in the previous paragraph leads us to suspect that resource availability should, in general, be higher at lower latitudes, where the greater diversity and abundance of plant and animal life suggests more opportunities for exotics. However, that same diversity also implies greater competition for those resources. Whether resource abundance or number of competitors is likely to be the dominant force in determining exotic establishment is unclear, but we can at least say that since both vary with latitude, so too should establishment success. A clearer prediction is that the lower species richness of birds on islands compared to proximal mainlands should lead to lower competition, and hence easier exotic establishment on islands.

It has also been suggested that since larger areas of habitat provide more resources in total, larger areas potentially could support more individuals of an exotic release. Since, as discussed in a previous section, larger populations are less likely to go extinct, establishment may be more likely in larger areas. Alternatively, however, establishment may be reduced in larger areas as these will tend to house more native

competitors (both in total and in each local community: Rosenzweig 1995, Srivastava 1999, Gaston & Blackburn 2000). Moreover, if larger areas result in more dispersed founding populations, that may lower the probability of successful establishment regardless of the effect of competitors, because of the greater difficulty in finding mates.

Third, establishment should be favoured at locations where exotics are challenged by fewer enemies, be they predators, parasites or diseases. Once again, it is difficult to identify precisely which enemies will be, or even are, more important in preventing the establishment of any given species, so studies tend to assume that more species generally will result in more enemies specifically. Thus, enemies should make it harder for exotics to establish at lower latitudes and in larger areas, where species richness is higher, but easier on islands in comparison to mainlands (Elton 1958).

Tests of the underlying processes (e.g. the influence of interspecific competition) determining location-level variation in establishment success are difficult for historical bird data, as the direct causes for failure are inaccessible to investigation. Studies of the influence of location thus regularly focus on testing the predictions outlined above about the influence of latitude, insularity, area and species richness. Unfortunately, the three sets of location-level variables produce contrasting predictions with respect to relationships expected. All three predict that islands should be easier to invade than mainland regions. The influences of climate and resource availability suggest that it should be easier to establish at lower latitudes or where species richness is higher, while resource availability predicts better establishment in larger areas. However, the effects of competitors and enemies predict the reverse in each case.

In support of the island prediction, bird species introduced to mainland Australia had a higher failure rate than bird species introduced to Australia's offshore islands (Newsome & Noble 1986). However, this result could be an artefact of differences in the establishment ability of the different sets of species introduced to mainland and islands. Additional support for the influence of insularity is hard to find. A study by Sol (2000) that took account of species identity in two independent island-mainland comparisons (New Zealand vs. Australia, and Hawaiian Islands vs. USA mainland) yielded no evidence that islands were easier to invade. This result was subsequently generalized in two global analyses of bird introductions, neither of which could find a relationship between establishment success and whether the introduction was to a mainland or island location (Blackburn & Duncan 2001a, Cassey 2003). The high proportions of exotic bird species found on islands appear to be a consequence of the many attempts to introduce birds to islands (see Section 3c), rather than any inherent feature of islands that make them easier to invade.

Latitude and habitat area are no better at predicting establishment success. Blackburn and Duncan (2001b) failed to find any relationship for birds between success and latitude of introduction in their global study. Case (1996) found a weak positive correlation between island area and the number of bird species introduced, but no evidence that area also influenced establishment. Smallwood (1994) similarly found no evidence that smaller Californian nature reserves were any harder for birds to invade than larger reserves.

Bird introductions also provide little evidence for the hypothesis (Elton 1958) that species richness influences establishment success. Case (1996) showed that the number of established bird species does not vary significantly with the richness of the native avifauna, nor indeed with the variety of potential mammalian predators. There is no difference in the establishment probability of birds introduced to Australia versus New Zealand, even though the former has more natives. These studies suggest that resident species richness is not important in determining the outcome of bird introductions. In fact, competition between native and exotic birds is probably unlikely to regulate exotic establishment because most aliens establish in highly modified habitats, such as farmland and urban areas, which are little used by native species (Diamond & Veitch 1981, Simberloff 1992, Smallwood 1994, Case 1996). In New Zealand, for example, it is rare, on the one hand, to see native bird species on farmland, other than recent colonists that appear to have moved in from Australia specifically as a consequence of the availability of such habitat, or, on the other hand, exotic bird species in native woodland, although Common Chaffinches (*Fringilla coelebs*), Common Blackbirds (*Turdus merula*) and Song Thrushes (*Turdus philomelos*) do appear to be moving in. While it is possible that these non-significant results for location are because opposing influences of climate/resource availability and competitors/enemies on establishment success cancel out, we suspect that they reflect the truth.

Fighting amongst themselves? Competition between exotics

Although competition between native and exotic birds is likely to be very limited because they tend to be segregated by different habitat requirements, that still leaves

open the possibility that establishment success could be mediated by competition amongst the exotics, at those locations which have received multiple releases. This argument has been propounded in a suite of studies of different island exotic bird faunas by Michael Moulton and colleagues (Moulton & Pimm 1983, Moulton 1985, 1993, Moulton & Sanderson 1996, Moulton *et al.* 2001, Brooke *et al.* 1995). Moulton *et al.* present two types of evidence in support of this idea.

First, the success of passerine introductions to both Hawaii and St Helena declines with time as the number of exotic species accumulates. Moulton *et al.* argue that this is because each successive release faces competition from an ever-larger number of established species. Second, successfully established species at several locations overlap less in their morphological characteristics than would be expected if established species were a random selection of all species released; this is termed "morphological overdispersion". Moulton *et al.* argue that this pattern arises because species are more likely to fail due to competition with other introduced species of similar morphology. Each of these conclusions has, however, been questioned.

For example, Duncan (1997) noted that although later introductions of passerine birds to New Zealand faced a greater number of already established species and were less likely to succeed, this relationship was confounded by introduction effort. Later introductions tended to be of fewer individuals and so were less likely to succeed for that reason. Similarly, Duncan and Blackburn (2002) showed that significant morphological overdispersion found by Moulton *et al.* (2001) among gamebirds established in New Zealand could not have resulted from competition. The distribution of releases over the islands in both space and time meant that it was highly unlikely that individuals from any two gamebird introductions would ever have met to compete. Instead, overdispersion could be explained by the fact that gamebird species were released in lower numbers if a similar species was already established in New Zealand. Duncan *et al.* (2003) pointed out that it is not only birds that are introduced to exotic locations. Later bird releases in New Zealand would also have faced a greater diversity and abundance of introduced mammalian predators. The effects of competition and predation in preventing historical establishment would be difficult to distinguish. These results for New Zealand do not rule out the importance of interspecific competition among exotics in other introduced bird assemblages, but they do bring into question the evidence presented in support of this mechanism.

In summary, the evidence garnered to date from historical bird introductions suggests no consistent effect of the release location on exotic success or failure. This might be considered somewhat surprising in the light of our earlier conclusion that environmental matching does seem to matter. Clearly, the compatibility between an introduced species and the environment into which it is released is more important than features of the environment *per se*. Does this mean that the same is true for characteristics of the species? Next, we consider the evidence that certain traits enhance the establishment success of the species that possess them.

c. Why some birds are better invaders than others: species-level effects

Travel around the world and you will encounter a range of exotic bird species. After all, more than 200 have successfully established somewhere (Cassey 2002a). However, there are certain exotics that you will encounter again and again. Examples include the Common Myna (*Acridotheres tristis*), Common Starling, House Sparrow and Rock Dove (Long 1981). Indeed, it is difficult to think of some of these species as anything other than aliens. A colleague of ours told us about walking through a park in London on a first visit to England, inwardly bemoaning the presence of so many exotic birds. Having studied exotics around the world, it was with a sense of embarrassment that the realization dawned that the House Sparrows, Common Starlings, Common Chaffinches and Common Blackbirds were actually native! The widespread success of certain introduced birds suggests that some species may simply be good at establishing in novel environments. Whether species differ inherently in their probability of establishing, and, if so, what characteristics regulate this difference, are two questions that have long interested ecologists (Elton 1958, Mayr 1965, Ehrlich 1989).

Do species differ in their probability of establishing?

Simberloff and Boecklen (1991) noted what they termed an "all-or-none" (AON) pattern for bird introductions to the Hawaiian Islands. Each species tended to establish successfully or to fail repeatedly on all islands to which it was introduced. Mixed outcomes, where a species established on only some islands, were rare (although see Moulton 1993, Moulton & Sanderson 1996, 1999, Duncan 1997, 1999). The AON

pattern suggests that some species are particularly good at establishing, and so succeed everywhere they are introduced, while other species are poor and so fail everywhere. That would imply in turn that characteristics of the species are key determinants of establishment success.

The observation of an AON pattern for introductions to Hawaii of itself provides little evidence for the existence of good and bad establishers. It may instead say more about the match between the Hawaiian environment and the requirements of the various species released. Conversely, the existence of good and bad establishers is not refuted by the objection (Moulton 1993, Moulton & Sanderson 1996, 1999, Duncan 1997, 1999) that most species do not follow a strict AON pattern, as the lists of successes and failures catalogued by Long (1981) and Lever (1987) both show. Release of a particularly poor invader at an especially amenable site, or vice versa, will muddy the statistics. The question is whether species do genuinely differ in establishment success, all else being equal. Blackburn and Duncan (2001b) addressed this question by fitting statistical models for establishment success in global bird introductions that controlled for the confounding effects of event-level and location-level variables. They found that each species tends to have a similar establishment outcome every time it is introduced, but that there are highly significant differences among species. In other words, some species genuinely seem to be better than others when it comes to exotic establishment. This leaves us with the question of why?

Why do species differ in their probability of establishing?

Bird species differ in a huge variety of characteristics, from size to colour, from physiology to behaviour. It seems reasonable to assume that amongst all these traits is one, or more, that varies in tandem with a species' probability of establishing. If that is indeed the case, such traits may act in one of three ways: they may pre-adapt a species to the new environment; they may favour population increase from the low numbers that were released; or they may constrain establishment success (Blackburn & Duncan 2001b).

Observed relationships between establishment success and environmental matching suggest that it is particularly important that an introduced species finds the exotic location to suit its ecological requirements. The likelihood of this should be higher if the exotic has catholic tastes. Thus, we would expect generalist species with broad environmental tolerances to be better at establishing than specialists (Ehrlich 1989). Several studies have found evidence that birds with broader diets were more likely to establish viable populations following release (Mclain *et al.* 1999, Cassey 2001b). Similarly, Brooks (2001) found that introduced birds categorized as habitat specialists were less likely to establish successfully. However, generalism is not found to enhance success in every case (Veltman *et al.* 1996, Sol *et al.* 2002). One problem here may be that most measures of it are relatively crude. For example, dietary generalism is often assessed by dividing food into a few broad types (such as vegetation, fruit, invertebrates, etc.), and summing the number of types a species uses. It is often the case that fewer dietary records exist for rare or more geographically restricted species, which can make such species seem artificially specialized (Gaston 1994). Since more abundant species are usually released in larger numbers (Section 3b), generalism may thus be confounded with effort, whose importance in establishment success we have already seen.

The likelihood that an exotic species can establish successfully may also be higher if the species has the flexibility to change its behaviour in response to novel challenges posed by the new environment (Mayr 1965, Sol & Lefebvre 2000, Sol *et al.* 2002). Exploiting new food resources, surviving new climates or avoiding new enemies may all require the modification of a species' existing repertoire, or even the invention of completely new forms of behaviour (Lefebvre *et al.* 2004). The hypothesis that behavioural flexibility enhances establishment (Mayr 1965) is supported by studies by Sol and colleagues (Sol & Lefebvre 2000, Sol *et al.* 2002), which show that established birds tend to have larger brains for their body size, and show more forms of innovative behaviour in their region of origin, than do failed species.

Most introduced species must secure a foothold in their new environment from a bridgehead of relatively few individuals. It is in these early stages that exotic birds are particularly vulnerable to the stochastic extinction processes that afflict small populations, and which so trouble conservation biologists (Section 4a). Thus, it has been suggested that species may be more likely to establish if, through rapid population growth, they can more quickly escape the risks posed by small population size (Moulton & Pimm 1986, Pimm 1991). Population growth rates are difficult to measure directly, so most tests of this idea utilize traits that are known to be related to them. Small body mass, short development time, multiple broods per season and large clutch size should all be indicative of a bird species with fast population growth.

However, it is also easy to think of reasons why species with these characteristics should also be less likely to establish. Small-bodied species with high rates of population growth also tend to have more variable population sizes. This could increase their risk of extinction following release because their population densities may be more likely to be pushed down to terminally low levels (Pimm 1991). If population variability is more influential than population growth rate, larger-bodied, longer-lived bird species, that have populations with slower rates of growth but that are more resistant to environmental fluctuations, would be expected to have a higher probability of establishment (Legendre *et al.* 1999, Forsyth & Duncan 2001).

Tests of these contradictory predictions for the influence of life-history characteristics of avian establishment success reflect them in their contradictory findings. For example, Cassey (2001b) found that birds with longer generation times were more likely to establish following introduction to New Zealand, whereas Griffith *et al.* (1989) reported higher establishment success for re-introduced species classified as "early breeders" than for those considered "late breeders". Cassey (2001b) also showed that establishment in New Zealand was more likely for species with larger clutches, thus finding support for the influence of both "fast" and "slow" life-history traits on success (see also Green 1997). However, other studies find the reverse relationship for clutch size (Duncan *et al.* 2001), or no relationship at all (Veltman *et al.* 1996).

Results for body size are no less equivocal (e.g. Veltman *et al.* 1996, Green 1997, Sol & Lefebvre 2000, Blackburn & Duncan 2001b, Duncan *et al.* 2001), and opposing trends can even be found within a single study. Cassey (2001a) showed that small body size equated to higher establishment success across bird species. Yet, when he compared species within the same taxonomic family, he found that larger-bodied species were more likely to establish. A pattern like this could arise if, for example, a primary role in establishment for high population growth rate (giving the negative relationship across species) was modified amongst close relatives by resistance to environmental fluctuations. Species related by family tend to have similarly high or low population growth rates (Owens & Bennett 1995), and so variation in success amongst them may depend on their relative ability to weather hard times, giving the positive relationship within families.

Some traits may just be bad news for any species attempting to establish a foothold at an exotic location. One commonly cited example is migration (Kolar & Lodge 2001). If it is hard enough to respond to the challenges of one new environment, migrants have to deal with two; that is, if they can even locate a wintering ground, or indeed if there is a wintering ground for them to locate. The physiological costs of preparing for a migratory flight cannot help either. Certainly, migratory species released in New Zealand have been less likely to establish than non-migratory species (Veltman *et al.* 1996, Duncan *et al.* 2003). However, even migration does not appear to be an unequivocal handicap, as Duncan *et al.* (2001) found no evidence that it hindered the establishment of bird species introduced to Australia.

d. Synthesis and future directions

Readers arriving at this point may by now be thoroughly confused by the variety of event-, location- and species-level characteristics that do or do not influence establishment success, or that in some cases seem to do both. They might recall the comment near the start of this section that some people have considered establishment success to be inherently unpredictable, and have some sympathy with this view. However, we are not so pessimistic. Recent studies that apply modern multivariate statistical techniques simultaneously to assess the influence of multiple hypotheses, while accounting for the confounding effects of non-independence among events have, to our minds, greatly clarified the likely causes of establishment success.

An important advance towards this clarification has been provided by analyses that quantify where in the taxonomic hierarchy variation in establishment success is located (Blackburn & Duncan 2001b, Cassey 2002b, Sol *et al.* 2002). What these studies show is that species tend to have similar establishment outcomes for all their introduction events. In other words, if you want to predict the likely success of a bird release, a good place to start is by checking on its past history of success. However, these studies also show that higher taxonomic levels have much less explanatory power to predict establishment success. In other words, the past introduction history of one species of sparrow tells you very little about the likely success or failure of another sparrow species. This has two significant implications for our understanding of establishment success.

First of all, the fact that related species do not exhibit similar levels of introduction success means that success will not be well predicted by any characteristic that species do share (Blackburn & Duncan 2001b). This includes most of the life-history

traits related to population growth rates, such as body size, clutch size and longevity. It also suggests that location-level characteristics are also unlikely to be good candidates for predicting success unless it is true that certain species tend to be introduced to certain environments. However, in that special case, variation in success would probably be due to variation in environmental matching, which is an event-level characteristic. Thus, the pattern of variation in establishment amongst species tells us why neither species-level nor location-level effects have been found to be good or consistent predictors of success.

The second implication is that what does influence establishment success must be a characteristic (or suite thereof) that does vary among closely related species. This suggests two broad classes of candidate (Blackburn & Duncan 2001b). The first class includes those species-level variables in which relatives do often differ markedly. Obvious candidates include abundance, geographical range size, or whatever factors (currently unknown) in turn underlie their variation. The second class of candidates is event-level effects, and in particular introduction effort. These effects are well known to be idiosyncratic, but that idiosyncrasy could be patterned such that different introduction events involving the same species share event-level characteristics. If so, then that would explain both the distribution of success across species, and the cause of that success (Duncan *et al.* 2003).

Cassey, Blackburn, Sol *et al.* (2004) have gathered information on effort for more than 800 bird introductions worldwide. They found that variation in effort was distributed across the taxonomic hierarchy in the same way as establishment success. In other words, species tend to be released in broadly similar numbers in all their introduction events, but those numbers differ on average between even related species. Blackburn and Duncan (2001b) showed why this could happen. Species that are more abundant or widespread in their native ranges have tended to be released in larger numbers, presumably because common species are more likely to be caught in large numbers. Moreover, Cassey, Blackburn, Sol *et al.* (2004) showed that many of the characteristics previously suggested to explain establishment success (including annual fecundity, body mass, migratory tendency, geographical range size, dietary generalism, and whether or not the release is on an island) are also correlated with effort. Recall the similar effects described above, for example the confounding of overdispersion and effort for Galliformes introduced to New Zealand (Moulton *et al.* 2001, Duncan & Blackburn 2002). When all the aforementioned characteristics were analysed together using multivariate statistics, only effort and habitat generalism were found to explain independent variation in establishment success (Cassey, Blackburn, Sol *et al.* 2004).

Thus, introduction effort currently seems our best candidate to explain variation in establishment success (Duncan *et al.* 2003, Cassey, Blackburn, Sol *et al.* 2004). Effort differs among species because species differ in their abundance and range size, and hence in their availability for capture, transport and release. However, effort is not the whole story. Cassey, Blackburn, Sol *et al.* (2004) also showed that average success and average introduction effort are not correlated across regions, and neither are they correlated across taxa. In other words, although increases in effort elevate success, they do not do so in a consistent manner across species. For example, similar average numbers of individuals released lead to the success of 70% of the introduction events in Sturnidae but only 30% in Muscicapidae, and 56% of the introduction events in Hawaii but only 35% in New Zealand (Cassey, Blackburn, Sol *et al.* 2004). This idiosyncratic taxonomic and regional variation in success reflects similar findings in other studies (Blackburn & Duncan 2001b, Duncan *et al.* 2001, Moulton *et al.* 2001): for example, that introduced gamebirds (Galliformes) were significantly less likely to establish in Australia than species of other orders. These as yet unexplained patterns of taxonomic and regional variation in establishment success are likely to be important topics for subsequent investigation.

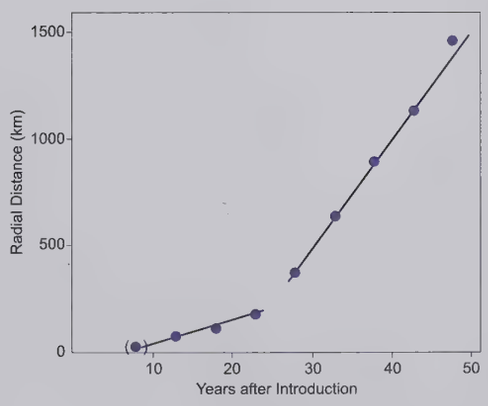

Figure 4. Plot of radial distance of the Common Starling's North American range versus time since introduction. Radial distance measures the effective radius of the range (specifically, √range area divided by √π). Rate of spread was initially relatively slow at 11·2 km/year, but then jumped to a higher but constant rate of 51·2 km/year. Plots of range expansion with this biphasic pattern are termed 'type II'. From Shigesada & Kawasaki (1997).

5. Spread following establishment

When the Common Starling was introduced in New York's Central Park, it took around a decade for the species to establish itself. Another decade passed before the species began slowly to spread, but then around a decade after that the rate of spread increased (Figure 4) so that within 80 years of release starlings had advanced right across the continent to the Pacific coast (Shigesada & Kawasaki 1997). At about the same time as the Common Starling was first introduced, a related species, the Crested Myna (*Acridotheres cristatellus*), was released and became established on the opposite side of the continent, in Vancouver. The myna initially became reasonably numerous but never spread, remaining confined to the environs of its initial release area. Spread is now unlikely, as the species has declined to low numbers (Duncan *et al.* 2003).

Birds probably have the greatest powers of dispersal of any organism. Individuals can cross continents in a matter of hours. Migrants of some species, such as the Arctic Tern (*Sterna paradisaea*) or the Sooty Shearwater (*Puffinus griseus*) undertake annual migrations that cover thousands of kilometres. Individuals of even relatively sedentary species can disperse over tens or hundreds of kilometres. Given that, and that a species has established a self-sustaining population at a location, why is it that only some species spread out from that bridgehead to invade the exotic location? Or more generally, why do species differ in the extent of their final distribution at any given location? How is that spread achieved? And why do species differ in how fast they spread? We address the last two questions first.

a. How do species spread? Pattern and rate

To understand how spread is achieved, it is necessary first to know the pattern of spread that needs to be explained. Data that allow us to plot the pattern of range expansion over time, such as those for the Common Starling, are relatively rare for birds. However, plots equivalent to Figure 4 also exist for the House Finch (*Carpodacus mexicanus*) in eastern North America (Shigesada & Kawasaki 1997); the Egyptian Goose (*Alopochen aegyptiaca*) in the Netherlands (Lensink 1998); the Common Waxbill (*Estrilda astrild*) in Portugal (Silva *et al.* 2002); and for the natural range increase of the Eurasian Collared Dove (*Streptopelia decaocto*) in Europe (Hengeveld 1989). In each case, spread shows the biphasic pattern illustrated in Figure 4, with an initial period of relatively slow increase followed by a higher but constant rate of spread. For the waxbill, the curve has a third phase as the growth rate slows, probably because all sites available for the species have been occupied. Spread in the initial growth phase has been calculated as 1·16 km/yr for the Egyptian Goose; 3·5 km/yr for the House Finch; and 11·2 km/yr for the Common Starling. These values increase to 4·59, 20·7 and 51·2 km/yr, respectively, in the faster second phase of spread. These biphasic growth curves are termed 'type II' (Shigesada & Kawasaki 1997), to distinguish them from type I curves, which show a single constant rate of range increase, and type III curves, where an initial linear rate of slow growth is followed by a period of growth at a faster but continually increasing rate. So, what do these type II curves tell us about how bird ranges expand? An answer can be obtained by examining the properties for different mathematical models of range expansion.

One simple way of thinking about an expanding range is as a growing population that is expanding the area it occupies by diffusion of individuals across the landscape. This is the approach taken in a classic paper by Skellam (1951). Skellam was able to show that if the invading population is growing exponentially, if the landscape is uniform, and if the diffusion of individuals across the landscape follows a random walk (i.e. they move randomly in a way that is similar mathematically to the well-known Brownian motion of smoke particles in air), then the invasion front advances at a constant velocity. In other words, the rate of range expansion is such that the points in a plot of radial distance versus time (e.g. Figure 4) fall on a straight line. Although the model assumes exponential growth, and hence that the population size grows without check to infinite size, the same prediction is obtained if the more realistic logistic pattern of population growth is assumed, where populations reach some finite carrying capacity. This is because diffusing populations grow by expansion at the range edge, where they will not have reached carrying capacity, and so probably are growing in an exponential manner. Skellam's model is a useful start, as some invading populations do follow this type I pattern of range expansion (Shigesada & Kawasaki 1997). Unfortunately, bird invaders are not among them.

Skellam's model assumes that ranges grow only by the random diffusion of individuals across the environment. One alternative is to assume "stratified diffusion", where spread occurs both by random diffusion of individuals from the core population, but also by occasional long-distance dispersal events. This process can be simulated by what is termed a "coalescing colony" model: the name speaks for itself. Under this model, the range initially expands through random diffusion at the wave front, as in Skellam's model, and so grows at a constant but slow rate. However, the population occasionally produces long-distance dispersers that go on to found new colonies, which then also start to expand. When these new colonies meet the expanding front of the core range, they are absorbed into it. When this first happens it results in an increase in the rate at which the core range expands, and this is maintained as subsequent colonies are encountered and absorbed (Shigesada & Kawasaki 1997). When the rate at which long-distance dispersers are produced is proportional to the radius (or circumference) of the core range (rather than its area), the change in radial distance over time follows the type II curve.

The coalescing colony model has two attractive features. First, it generates the biphasic pattern of range expansion over time characteristic of birds (e.g. Figure 4). Second, it models a pattern of dispersal that bird invaders appear to follow. For example, Hengeveld (1988) showed that the distribution of dispersal distances of individual Eurasian Collared Doves included both long-distance and short-distance events as the species spread across Europe. Several of the exotic bird species introduced to the main islands of New Zealand have colonized outlying islands, which in many cases involve dispersal over several hundred kilometres of ocean. Of course, these colonies will not coalesce with the core populations, but they are indicative of long-distance dispersal events. More generally, ringing returns from native British birds show that most individuals of most species disperse relatively short distances (under 5 km), both as juveniles and adults, but a few individuals travel long distances (over 100 km; Paradis *et al.* 1998). The spread of the House Finch following its introduction to the eastern USA has involved both neighbourhood diffusion and jump dispersal events, the latter resulting in small satellite populations that eventually coalesced with the core part of the range (Shigesada & Kawasaki 1997). These satellites seem to develop preferentially in good-quality habitat (Gammon & Mauer 2002).

Exploring the features of different models for spreading populations allows us to identify processes that can, and also those that cannot, explain the patterns of range expansion we see for invasive birds. Nevertheless, while these models allow us to examine factors affecting the rate of expansion in a few typically widespread exotic species, no study has yet quantified or examined the reasons underlying interspecific variation in rate of spread.

b. Determinants of final distribution

Although no study has considered the reasons behind interspecific variation in the rate of spread, three studies have examined why different introduced species end up with different final range sizes at the exotic location (Duncan, Blackburn & Veltman 1999, Duncan, Bomford *et al.* 2001,Williamson 2001). These studies concern the exotic bird assemblages of Australia and New Zealand. We highlight three factors that these studies find to be consistently related to exotic range size.

First, exotic species have larger ranges if the exotic location has larger areas of suitable habitat or environmental conditions. In New Zealand, the species with the largest geographical ranges were those whose preferred habitat was most widespread, specifically species that use extensive human-modified habitats such as farmland. On the larger and more climatically varied continent of Australia, exotic species with larger geographical ranges were those with a greater area of more climatically suitable habitat available. This variable explained more than two-thirds of the variation in final range size amongst these species.

Second, exotic species have larger ranges in the exotic location if they have larger native geographical range sizes. This pattern could arise because species with larger native ranges may have broader environmental tolerances or use more widespread resources. This might not only enhance establishment, as we discussed in Section 4c, but also allow a greater extent of spread across the exotic environment.

An alternative possibility is that the range-size effect could arise from the general trend for more widespread species to be introduced in larger numbers (see Section 4d). Species with large founding populations might get a head-start in establishment that allows them to appropriate a greater proportion of the resources available for exotic invaders in the new environment. In practice, this initial advantage could have compounded itself—those species initially able to capture a greater share of resources would have had faster population growth and rate of spread, allowing them further to pre-empt resources at newly colonized sites as their ranges expanded. Two pieces of evidence are consistent with this view for exotic bird species in New Zealand. First, species introduced with greater effort were more likely to spread and achieve a larger geographical range size (Duncan *et al.* 1999). Second, the relationship between range size and effort was most pronounced among closely related species. Related species are more likely to compete for similar resources, and so it is amongst these species that we would expect any head-start given by variation in introduction effort to be most important (Duncan *et al.* 1999). This explanation implies that competition may play a role in limiting the range sizes of established species, even though it does not appear to influence establishment success (see Section 4b). Nevertheless, it requires further testing to establish whether the relationship between introduction effort and exotic range size holds beyond the single example of New Zealand. It does not hold for Australia (Duncan *et al.* 2001).

Third, the geographical range size of exotic species in New Zealand and Australia relate consistently to several life-history traits (Duncan, Blackburn & Veltman 1999,

Cassey 2001b, Duncan, Bomford *et al.* 2001, but see Williamson 2001). More widespread species tend to be those with life-history traits associated with high population growth rates (see Section 4c). The reason for these relationships may be similar to that posited to explain why such species should be more likely to establish viable populations following release: they may be less vulnerable to local extinction following colonization of unoccupied sites (Gaston 1988).

Whatever the reasons for the relationships just described, they suggest that the extent of spread by exotic invaders may depend on both characteristics of the species and of the location. This is in contrast to the likelihood of establishment in the first place, which seems to be primarily determined by idiosyncratic characteristics of the specific introduction event. Thus, location- and species-level effects may not determine which species make it into the exotic environment, but may be much more important in determining which species can spread across it.

6. Impact of avian introductions

Introduced species are organisms that have not evolved over time with the recipient community, so once established they have the potential to produce significant ecological changes. The importance of their impact will depend on a combination of the abundance, distribution and impact per individual of the invader (Parker *et al.* 1999). In the region of introduction, invaders are often released from the factors that could have limited their abundance and distribution, such as competitors, predators, pathogens or parasites (Torchin *et al.* 2003). This may allow them to grow in excess, spread over wide regions and become pests. Native species, on the other hand, may not possess mechanisms to respond to novel competitors, predators, pathogens or parasites, making them more vulnerable to invaders. Despite this, ecologists estimate that only a minority of species that are introduced cause major impact on the recipient community (Williamson 1996). The reasons why some species have greater impact than others remain largely unknown, and to uncover them should be a major goal of future research.

Birds have caused, and are still causing, a variety of ecological impacts in the regions where they have been introduced. Surprisingly, however, the impact of bird invaders has been largely under-appreciated by ecologists, especially when compared with that caused by other vertebrates (see e.g. Ebenhard 1988, Lever 1994). Most avian invaders occur in human-modified habitats rather than in pristine habitats (Case 1996), so their ecological impact is often assumed to be relatively unimportant. As a result, little effort has been expended in evaluating it rigorously. However, if we do not measure the impact of non-indigenous birds, we will never know the real magnitude of the problem. In addition, introduced birds not only cause ecological impacts but they also impose substantial economic costs to human societies (Lever 1994). Although our understanding of the quantitative ecological and economic impact of birds is currently poor, we have examples of several major effects of avian invaders on native individuals, populations, genetic pools and communities, as well as those on human societies.

a. Individual and population effects

Non-indigenous species may predate indigenous species, limit their access to resources through competition and transmit parasites and pathogens to them, all of which may negatively affect the native populations. Predation is perhaps the strongest impact of introduced vertebrates. This is clearly exemplified by the devastating effect of rats and cats introduced into islands that lacked native predators (Courchamp *et al.* 2003, Blackburn & Gaston 2005). In birds, predators are uncommon among the species that have ever been introduced, but a negative impact through predation has nonetheless been documented. For example, the Pacific Marsh-harrier (*Circus approximans*), introduced into Tahiti in 1880 to control introduced rats, is one of the causes of the imminent threat of extinction faced by the Polynesian Imperial-pigeon (*Ducula aurorae*) (Thibault, 1988).

Introduced birds may also affect native birds through competition for limited resources. In North America, for example, Common Starlings have been found to usurp nests of several North American hole-nesting species (Ingold 1996, 1998). Competition for either nesting sites or food supplies with natives has been suggested for over 20 introduced bird species (Lever 1994). However, there are surprisingly few instances in which competition with introduced species causes a decline in number of resident species (Davis 2003), so whether or not competition negatively affects entire

populations remains debatable. In the case of starlings, a recent comparison of densities of native cavity-nesting species before and after invasion of sites by the starling revealed that only five out of 27 species examined exhibited significant negative effects potentially attributable to starlings (Koenig 2002). Moreover, a further five species increased following starling colonization, including the Red-bellied Woodpecker (*Melanerpes carolinus*), one of the only species for which there was good evidence of a high frequency of nest usurpation by starlings. As Koenig (2002) points out "Despite their rapid spread, striking abundance, and aggressive nature, starlings appear thus far to have had little negative affect on the native cavity-nesting bird species with which they are known to interfere". It remains to be investigated if this conclusion also holds for the other introduced species suggested to compete with native species.

Introduced birds may also affect individuals and populations of native species through the transmission of parasites and pathogens. A well-studied example is the avian malaria that is strongly implicated in declines of native passerine birds in Hawaii (van Riper *et al.* 1986). Malaria was introduced to this island through exotic birds kept by settlers, and its transmission was facilitated by the subsequent introduction of the southern house mosquito (*Culex quinquefasciatus*). Native birds were not resistant to malaria and succumbed rapidly to its detrimental effects. Avian malaria has contributed to the extinction of at least 10 native species and threatens many more.

b. Genetic effects

Closely-related species sometimes interbreed and produce fertile hybrids. This phenomenon is relatively rare in nature, where interbreeding is usually avoided by the action of geographical, ecological, behavioural or morphological barriers. Yet, it may be facilitated when a species is introduced in a region that contains a close relative (Rhymer & Simberloff 1996). Given that alien and native species were previously separated by geographical barriers, they may have been less likely to have evolved ecological, behavioural or morphological mechanisms to avoid interbreeding.

Hybridization is a conservation issue because it may alter the genetic structure and reduce the fitness of native populations (Mooney & Cleland 2001). A number of cases corroborate the importance of this phenomenon in birds. In Europe, the long-term survival of the Endangered native White-headed Duck (*Oxyura leucocephala*) is threatened by hybridization with the American Ruddy Duck (*Oxyura jamaicensis*), an introduced species currently expanding on the European continent. Likewise, hybridization with introduced Mallards (*Anas platyrhynchos*) has been related to the population decline of the Pacific Black Duck (*Anas superciliosa*) (Rhymer & Simberloff 1996). Whilst hybridization is particularly common in ducks, it is also observed in other taxonomic groups. The nominate race of the Madagascar Turtle-dove (*Streptopelia picturata*), introduced to the Seychelles from Madagascar, has so massively hybridized with the local race *rostrata* that a hybrid form resembling the invaders now lives in the Seychelles.

c. Community effects

Introduced birds have the potential to alter the composition of the recipient community through a variety of mechanisms, although evidence for such an impact is only available for a few case-studies. One of these is the dispersal of seeds from the ornamental plant *Lantana* by Common Mynas introduced in the Hawaiian Islands (Lever 1994). This plant was introduced from Mexico in 1958 to local gardens, where it serves as a major food supply for Common Mynas. Thanks to subsequent seed dispersal by mynas, the plant has become an agricultural problem in the islands.

A second example of the impact of a bird invader on the community structure comes from Mute Swans (*Cygnus olor*) introduced in the USA: experimental exclosures have shown that grazing by swans affects the diversity and density of aquatic plants (Cobb & Harlin 1980). This is one of the few cases where the impact of a bird has been evaluated experimentally.

d. Effects to human societies

Invaders are widely recognized as the cause of significant economic and health problems to human societies, although the actual magnitude of these impacts has rarely been quantified. Perhaps the most common economic impact associated with introduced birds is the damage caused to agricultural crops. At least 37 naturalized species

from four taxonomic orders have been reported to affect crops significantly (Lever 1994). In Australia, for example, the Common Starling is a pest of soft fruits and cereals, causing the loss of 10–15% of certain crops. In general, species that are considered to be pests in their natural range also become pests in the places where they are introduced (Lever 1994), a pattern with which the Common Starling fits well. However, the reverse is not always true. Species that produce little damage in their natural range may become pests when introduced in places where the natural factors that limit their abundance and distribution are absent. The Ring-necked Pheasant (*Phasianus colchicus*), for example, is regarded as harmless in its native range in the Middle East and Far East, but causes significant losses to the agriculture in many of the regions where it has been introduced (Lever 1994).

Introduced birds may also act as a reservoir of severe diseases that affect humans and domestic animals. Feral pigeons, descended from Rock Doves introduced in many regions of the world, carry diseases such as salmonellosis, tuberculosis, ornithosis and Newcastle disease (Johnston & Janiga 1995). Whilst there is no direct evidence that the diseases have been passed from pigeons to humans, the risk cannot be discounted.

The literature also reports a variety of additional problems that avian invaders cause on human activities. In Britain, for example, the introduced population of Canada Geese (*Branta canadensis*) not only is regarded as causing significant agriculture damage, but also has been implicated in damage to amenity sites, eutrophication of waterbodies, and as a threat to aircraft safety (Wattola *et al.* 1996).

7. Solutions to the problem of avian invaders

The seriousness of the impacts of avian invaders should not be underestimated, given how unpredictable their effects are. Future exotic introductions should best be avoided, and strategies to deal with species that have already been introduced urgently need to be implemented. The solution to the problem of invaders will be difficult, but not impossible. Five types of measure appear to be priorities (Genovesi 2000, Myers *et al.* 2000, Genovesi & Shine 2002):

1. *Research.* This is usually the first cry of the researcher, but with good reason. Research is necessary to help prevent new invaders, to evaluate the ecological, economic and health problems the current invaders generate, and to develop efficient measures to help mitigate these problems. For decision-taking with respect to these issues, it is particularly important that we improve our ability to predict the consequences of introducing a given alien species. Good progress has been made in the last decades in our predictive power, as we hope to have demonstrated throughout this review, but important aspects remain to be investigated. Predicting the impact of introduced species is perhaps one of the major unresolved issues in birds, and in other organisms as well (Ricciardi & Rasmussen 1998, Parker *et al.* 1999). Assuming that we can define and measure impacts, we can, in principle, apply comparative methods to identify factors that distinguish introductions with little effect from those with large effect, as has been done for other invasion transitions. This information can then be used in risk-assessment models.
2. *Monitoring.* The development of monitoring programmes for alien birds is of key importance for the identification of alien introduction and invasion pathways, the early detection of invaders, and the assessment of alien threats. Given that birds have good dispersal abilities and may easily reach distant regions, this information should be made available to other countries through regional and global information systems (Ricciardi *et al.* 2000). Intensive monitoring is particularly feasible in birds, as birdwatching is a widespread activity in many regions of the world.
3. *Legislation.* Laws and regulations may serve to encourage countries to design management strategies, to prevent the import of high-risk species, to prohibit deliberate introductions and to force captive collections to implement measures that reduce the chance of escapes of non-native species. For example, because of the ecological problems associated with Ruddy Ducks, the UK government has, since 1995, prohibited trade in the species without licence (Hughes 1996). States are a potential source of avian invaders for other states, and hence they should take appropriate co-operative actions to minimize risks. The Bern Convention, for example, specifically states that the contracting parties must undertake strict control to prevent the introduction of non-native species.
4. *Mitigating impact.* The design of control strategies to limit or eradicate high-risk non-indigenous species is the only solution once a species is established. There exist a variety of methods to control or eradicate birds (Genovesi 2000), including

trapping, population sterilization, behavioural management and biological control. The decision to use one or another method will critically depend on the characteristics of the introduced population and the impact it produces. Although vertebrates are often difficult to control, success in reducing their population density and even reaching a complete eradication can be achieved in well-planned programmes (e.g. Myers *et al.* 2000). In the UK, for example, research into control programmes led to the conclusion that shooting was the most effective means to control the growing introduced population of Ruddy Ducks (http://www.unep-wcmc.org/aewa/eng/info.htm). After informing the public about the programme, and despite some controversy, a three-year trial started in the early 1990s to assess whether the eradication of the species was a feasible option. More than 2500 Ruddy Ducks were shot within this period, halving the population size. Based on these data, it was estimated that the UK Ruddy Duck population could be reduced to fewer than 175 birds in less than six years.

5. *Informing the public*. The public needs to be aware of the serious problems that introduced species generate, so that no further irresponsible introductions are carried out. The support of the public is also important to influence political decisions and, as we have just seen, for the successful implementation of control strategies.

The growing frequency of non-indigenous species is threatening global biodiversity, ecosystem functioning, national economies and human health, making it urgent that we implement strategies to mitigate this impact. Fortunately, and despite early scepticism, our understanding of the invasion process has significantly improved during the last few years. This has broadened our ability to predict and prevent invasions, providing a good starting-point for the development of regional and global strategies against invaders. Although much work still remains to be done, we should be optimistic about the possibility that the problems posed by non-indigenous birds can be solved in the not too distant future.

Introduction to Volume 10

It hardly seems a year since we were despatching Volume 9 to the printers. Indeed, only three years have gone by since we waved off the last of the non-passerine volumes, in the company of Errol Fuller's evocative foreword on extinct birds. At that time, how many of us honestly felt that the Ivory-billed Woodpecker (*Campephilus principalis*) should have been included in the foreword rather than in the main body of the Picidae text? How many believed the reports that the species might still exist in remote backwaters of such a modernized country as the USA, with such a vast birding public, when there had been no confirmed records for over 50 years? Conservation efforts, in all their many guises, can amount to an exceedingly depressing excercise, with massive personal input and often with virtually no returns to show for it all, but when the years and the countless expeditions in quest of such a creature are rewarded by the rediscovery of such a magnificent species as the Ivory-bill, it puts fresh heart into all of us. Perhaps, after all, there really is some reason in continuing the struggle.

As each volume comes round, we seem less capable than before of excluding material. This present volume includes what will be (we trust!) the longest family text in the entire series. We imagine that some may consider it too long, but we hope that most readers will agree with us that it is so packed with interesting detail that it would have been a great shame to have cut it back. Certainly, Turdidae contains many of the most familiar and best-studied of all bird species, so it should perhaps come as no surprise that this family should end up so long and detailed.

It has been quite an effort to fit all the material in between the covers, and this time we really have come very close to the limit: any more weight and the book simply would not hold together. Indeed, even to achieve this we have had to make a concession: rather than eliminate information, we have had to change to slightly thinner paper, in order to keep within the weight limit. The good news is that this volume was already predicted as being very long, and we foresee only one other of the remaining volumes as possibly struggling with the same sort of problem.

One reviewer has suggested that we ought to save pages by avoiding blank pages between some plates, either by tacking the information for one plate on to the end of the material for the previous plate, or by allowing the option of having full-page plates on right-hand pages. Readers will appreciate that we are keener than anybody to keep such blank pages to a minimum, but we hope that most would, like us, prefer to avoid either of the possible aforementioned solutions, as being both confusing and messy.

Continuing with our collection of selected essays on unrelated subjects related to birds, we are very pleased that the foreword in this volume is dedicated to a highly topical issue that affects the whole biosphere in a variety of ways, namely the subject of introduced species, in particular, of course, introduced bird species. The team of authors is made up of specialists on the subject, all of whom are involved in some of the latest and most detailed studies of this increasingly relevant issue.

Acknowledgements

Always of prime importance in the preparation of any of our volumes is the input of museums and similar institutions. We particularly thank the British Museum of Natural History at Tring (Robert Prys-Jones, Michael Walters, Mark Adams), the American Museum of Natural History in New York (Paul Sweet, Shannon Kenney, Mary LeCroy), the Louisiana State University Museum of Natural Science (Van Remsen, Steve Cardiff, Donna Dittmann), the Smithsonian Institution, National Museum of

Natural History in Washington (James Dean), the Departamento de Zoologia Universidade de São Paulo (Luís Fabio Silveira) and the Colección Phelps de Venezuela (Miguel Lentino). We are also very grateful to the Royal Museum for Central Africa in Tervuren (Michel Louette, Gert Boden, Alain Reygel), the Field Museum in Chicago (David Willard, Shannon Hackett, Mary Hennen), the Peabody Museum at Yale University (Kristof Zyskowski), the National Museums of Scotland in Edinburgh (Bob McGowan), and the Natuurhistorisch Museum at Leiden (René Dekker).

The other principal form of reference is bibliographical, and the number of references "processed" in one way or another just refuses to stop growing. We have received a great deal of assistance in this field from a wide array of generous sources. We should like to offer our particular thanks to the British Museum of Natural History at Tring (Alison Harding), the Bavarian Ornithological Society (Juliane Diller), the Darwin Museum in Moscow (Igor Fadeev), the Durban Natural Science Museum (David Allan), the H. L. White Library in Australia (Pamela Copley), the Muséum National d'Histoire Naturelle in Paris (Jacques Cuisin), the Museum of Zoology of the University of Michigan (Janet Hinshaw, Janet Griffin-Bell), the Niven Library in South Africa (Margaret Sandwith), the Royal Danish Academy of Sciences and Letters (Bjarne Stavnshøj), the Western Foundation of Vertebrate Zoology (Linnea S. Hall), the Yamashina Institute for Ornithology (Shigeki Asai), the Zoological Museum of State, Moscow (Eugeny Koblik), Richard Banks, Murray Bruce, Bob Dickerman, Diego Calderón Franco, Lloyd Kiff, Miguel Lentino, Vladimir Loskot and Travis Rosenberry.

The content of the volume has benefited notably from many generous contributions, for instance of referees, or those who have most kindly made their unpublished information available to us, or have cleared up particular doubts. Our warmest appreciation is due to Ulf Beichle, Geoff Carey, Peter Clement, Guy Dutson, Jon Fjeldså, Héctor Gómez de Silva, HANZAB and Peter Higgins, Jesper Hornskov, Hannu Jännes, Guy Kirwan, Barbara MacKinnon, Evgenii Panov, Mark Pearman, Pamela Rasmussen, Ueli Rehsteiner, Craig Robson, Phil Round, Paul Salaman, David Snow, Helen Temple, Joe Tobias, Marcelo Vasconcelos, Gary Voelker and Paul Wood. Claire Spottiswoode generously provided a great deal of assistance in the huge task of the Turdidae species accounts.

We also owe a great deal to the tireless efforts and expert advice of Murray Bruce, Normand David, Edward Dickinson and Alan Knox, who have solved a wide variety of enigmas related to scientific nomenclature, type descriptions and so on. Likewise, we are deeply indebted to Robert Ridgely, who continues to check through every single species map that takes in the Neotropics.

Guy Tudor continues to put his large photo collection at our disposal, and this proves invaluable in several different ways. We thank him for his continuing support.

The French, German and Spanish names used in the volume continue to be supplied from the customary sources, and once again we gratefully thank Normand David, Christoph Hinkelmann and Peter Barthel, and Eduardo de Juana and their various colleagues for helping out most promptly whenever any doubts have arisen.

The individual authors and artists would like to thank the following: Mark Adams, David Allan, Per Alström, George Amutete, Mark Anderson, George Angehr, W. J. Arendt, J. Baillie, S. van Balen, Keith Barker, Clive Barlow, Roger Barnes, John Bates, Bruce Beehler, Leon Bennun, Pamela Beresford, Linda Birch, Tommy Bird, K. D. Bishop, Rauri C. K. Bowie, Adam Bowley, Tom Brooks, Pierre Bulens, John Caddick, Hugh Chittenden, Anwaruddin Choudhury, Lars Christiansen, A. Cibois, Robin Clarke Gemuseus, Peter Clement, Callan Cohen, Dan Cole, C. Z. J. Collar, Nigel Collar, Jo Cooper, Norbert Cordeiro, Matthieu Le Corre, Sara Davidson, James Dean, W. R. J. Dean, Morten Dehn, René Dekker, Ron Demey, Edward Dickinson, Janis Dickinson, L. Dijksen, Lars Dinesen, Robert Dowsett, Françoise Dowsett-Lemaire, Sergei Drovetsky, Guy Dutson, Siegfried Eck, Jonathon Ekstrom, Renate van den Elzen, David Fisher, Jon Fjeldså, Roger Fotso, Mary Gartshore, Thomas Ghestemme, Héctor Gómez de Silva, Martin Goodey, Gus Haak, Loius Hansen, Alison Harding, Douglas Harebottle, Oren Hasson, Frank Hawkins, Marc Herremans, Eric Herrmann, Mike Hill, Erik Hirschfeld, J. Hornskov, Valerie Howe, Tim Inskipp, Colin Jackson, Stuart Keith, Shannon Kenney, Jim Kerr, Howard King, Arturo Kirkconnel, Guy Kirwan, René-Marie La Fontaine, Olivier Langrand, Marc Languy, Thomas Lehmberg, L. Lens, Pete Leonard, Liu Liang-Li, Jeremy Lindsell, Michel Louette, Duncan MacNiven, Sharon Maree, Thomas Martin, Jon McCracken, Bob McGowan, Rob McKay, Bob Medland, Martim Melo, Amanda Martin, Suzanne Milton, Andy Mitchell, Anders Pape Møller, Juan Moreno, P. Morris, David Moyer, Simon Mustoe, Bill Newmark, Terry Oatley, David Okines, D. Outlaw, Alfred Owino, Mark Peck, Andy Plumptre, C. Pridham, Robert Prys-Jones, K. N. Rabenold, Hugo Rainey, R. Ranft, P. C. Rasmussen, Van Remsen, Andy Rhodes, Nathan Rice, T. R. Robinson,

P. D. Round, Paul Salaman, Peter Ryan, Roger Safford, Volker Salewski, Brian Schmidt, Sigrid Schwarz, Derek Scott, Cagan Sekercioglu, Stuart Sharp, Jackie Skeer, Adrian Skerrett, D. W. Snow, Claire Spottiswoode, Frank Steinheimer, Jim Stevenson, R. Strewe, Paul Sweet, Bryan Thomas, the late B. T. Thomas, Till Topfer, Mick Turton, K. Ueda, Pedro Vaz Pinto, G. Voelker, Michael Walters, Matthias Waltert, Effi Warr, Ben Warren, K. Weerakoorn, D. Wells, Lyn Wells, Jan Wilczur, David Willard, Robin Woods, Jo Wrigley and Kristof Zyskowski, as well as the American Museum of Natural History, the British Museum of Natural History, the Smithsonian Institution, the Trust for Oriental Ornithology in Eastbourne, the British Museum of Natural History at Tring, the Natuurhistorisch Museum at Leiden, the National Museums of Scotland in Edinburgh, the Field Museum of Natural History, the National Museums of Scotland, the Peabody Museum at Yale University, and the Staatliches Museum fuer Tierkunde in Dresden.

The authors of the foreword have a special acknowledgement to make. Their project was supported by a Ramón y Cajal grant from the Ministerio de Ciencia y Tecnología (Spain), and by the EC within the FP 6 Integrated Project "ALARM" (GOCE-CT-2003-506675), to Daniel Sol; and a Leverhulme Trust grant (F/00094/AA) to Tim Blackburn and Phillip Cassey.

And last, but far from least, as ever we must close by offering our grateful thanks for help of all sorts kindly offered by Mª Josep de Andrés, Raül Aymí, Dolors Buxó, Juan Antonio Cantí, Cam Christie, Remko van Doorn, Marc Duquet, Fortunato Frías, Rosa Llinàs, Albert Martínez-Vilalta, Isabel Martínez, Rafael Martínez, Ángela María Naranjo, Mary and Jim Ramsay, Olga Rius, Jamer Rivera, Pedro Rubio, Iván Teba, Virgínia Toledo, Aurea Vilalta, Diane Willis, Nicole Wirtz and Jo Wrigley. Toni Llobet continues to occupy the back cover, with another fine illustration; once again, we are most grateful to him.

PASSERIFORMES

Class AVES

Order PASSERIFORMES

Suborder OSCINES

Family CAMPEPHAGIDAE (CUCKOO-SHRIKES)

- Small to medium-sized passerines with broad-based bill, moderately long tail and thick, erectile rump feathers; some species brightly coloured.
- 13–38 cm.

- Sub-Saharan Africa, Malagasy, south and east Asia, Australasia and western Pacific islands.
- Forest, woodland, savanna, scrub and mangroves.
- 9 genera, 86 species, 316 taxa.
- 4 species threatened; none extinct since 1600.

Systematics

The family Campephagidae is currently considered to comprise nine genera in five distinctive groups. These are the cuckoo-shrikes in the genera *Pteropodocys*, *Coracina*, *Campephaga*, *Lobotos* and *Campochaera*, the trillers in the genus *Lalage*, the minivets in *Pericrocotus*, the flycatcher-shrikes in *Hemipus*, and the wood-shrikes in the genus *Tephrodornis*. The family is confined to the Old World and is mainly tropical in distribution, ranging from sub-Saharan Africa, the Malagasy Region and southern Asia eastwards to New Guinea, Australia and the islands of the south-western Pacific Ocean. One species, the Ashy Minivet (*Pericrocotus divaricatus*), is found as far north as south-east Russia and Japan.

The fossil record provides no direct evidence of the family's ancestry, but it has long been maintained that, in the case of *Coracina*, by far the largest genus in the family, the populations of the Indo-Australian Archipelago originated as a result of radiation from south and south-eastern Asia, and that the Pleistocene tropical Sunda Basin and the Australian mainland acted as important centres of speciation. This hypothesis proposes a common south Asiatic origin of all Afrotropical and Indo-Australian forms of *Coracina*. On the other hand, in addition to the fact that species diversity among the cuckoo-shrikes and the trillers is greatest in the area from Wallacea east to the Australia–New Guinea region, these groups are represented in this region by more diverse lineages, including at least five infrageneric groups of cuckoo-shrikes and three of trillers, and such local endemics as the Golden Cuckoo-shrike (*Campochaera sloetii*) and the Ground Cuckoo-shrike (*Pteropodocys maxima*). In view of these factors, it has also been proposed that this region was the likely cradle of evolutionary radiation. An origin in southern mainland Asia is assumed for the minivets, the flycatcher-shrikes and the wood-shrikes on the basis of their current distribution, which is centred on southern and south-eastern Asia.

Despite the vernacular name, cuckoo-shrikes are not related to either the cuckoos (Cuculidae) or the shrikes (Laniidae). The "cuckoo" part of the name probably derives from the grey coloration of many of the species, some of which also have conspicuous cuckoo-like barring on the underparts, and the name "shrike" from the strong, hooked and notched bill. Various other English names are applied to different species, including "greybird", obviously again because of the predominantly grey coloration of many, and "caterpillar-bird", because of the preponderance of caterpillars in the diet of several species. The name "cicadabird" is commonly given to a group of *Coracina* species that were formerly separated in the genus *Edolisoma* because of differences in bill shape and plumage (see Morphological Aspects), and is derived from the insect-like calls of some of these campephagids (see Voice). Likewise, the trillers are named for their calls, while the flycatcher-shrikes and the wood-shrikes bear a superficial resemblance to the laniid shrikes and, in the case of the former, are similar to the Old World flycatchers (Muscicapidae) in their foraging behaviour.

Traditional classifications place the family Campephagidae between the wagtails and pipits (Motacillidae) and the bulbuls (Pycnonotidae). Structurally, the family is corvoid, crow-like skeletal features including the humeral fossa, the configuration of the palate, the nasal bones and other parts of the skull, and the lack of an apterium in the spinal feather tract. In most of these features the cuckoo-shrikes resemble the Old World orioles

The most diverse campephagid genus, Coracina, *contains 50 species. Some of these are inconspicuous, while others are large and often seen in high, undulating flight over forests and open country, their bursts of wingbeats interspersed with downward glides on stiffly held wings. Although they are mainly distributed in continental south Asia and Australia, high mobility has led them to colonize remote oceanic islands in the Malagasy Realm as well as Indonesia, Polynesia and Melanesia, where they have diversified into a multitude of forms, such as the* ***South Melanesian Cuckoo-shrike****.*

[*Coracina caledonica caledonica,* New Caledonia. Photo: Roland Seitre]

When perched, members of Coracina *are elongated birds with the upright posture, short tarsi and weak feet associated with an arboreal lifestyle. They are known by many regional monikers, but most are now called "cuckoo-shrikes". Even though related neither to cuckoos (Cuculidae) nor shrikes (Laniidae), the name is fairly apt because they combine plumage patterns of the former and the stout hook-tipped bills of the latter. The* ***White-bellied Cuckoo-shrike*** *is typical in its soft, dense plumage, and in lacking any hint of bright colour. Like many of its congeners it is essentially grey, with darker feathering on the wings, tail and head.*

[*Coracina papuensis artamoides*, Georgetown, Queensland, Australia. Photo: Graeme Chapman]

(Oriolidae), a group to which they were for long thought only distantly related. DNA–DNA hybridization first indicated a close relationship to the Oriolidae, and led C. G. Sibley and B. L. Monroe to combine the cuckoo-shrikes and the orioles into one tribe, the Oriolini, within their expanded family Corvidae. Studies of proteins corroborate a close association between the orioles and the cuckoo-shrikes. There are also, however, significant structural differences between the two groups, including some features of the skull, and the possession of ten secondaries, as opposed to the eleven commonly found in the orioles. The erection of the tribe Oriolini has not, therefore, gained general acceptance, and the Campephagidae and Oriolidae have subsequently been retained as separate families, pending further study. It should also be noted that the trillers in the genus *Lalage* have all the cranial features of the cuckoo-shrikes.

The genus *Chlamydochaera*, with only one species, the Black-breasted Fruithunter (*Chlamydochaera jefferyi*) of Borneo, was originally included in the Campephagidae, but it has the distinctive syringeal morphology of the true thrushes (Turdidae) and the muscicapid flycatchers, while DNA–DNA hybridization studies also suggest a turdine relationship. In addition, S. L. Olson has pointed out that the morphology of the humerus corroborates this placement and further negates any possible relationship with the Campephagidae. On plumage and zoogeographical grounds, *Chlamydochaera* is probably closely related to the turdine genus *Cochoa*.

Retention of the genus *Tephrodornis* in the Campephagidae is problematical. DNA–DNA hybridization indicates that the genus is related to the helmet-shrikes (Prionopidae), and not to the orioles, and Sibley and Monroe placed it in the tribe Vangini, as part of the bush-shrike subfamily Malaconotinae, within their enlarged Corvidae. Although such evidence suggests that *Tephrodornis* should perhaps be moved into the shrike assemblage, such a change is considered premature without more corroborative evidence.

The validity of two genera within the cuckoo-shrike assemblage is open to debate. The monotypic genus *Pteropodocys* is split from *Coracina* on the basis of its morphology. It is a ventrally barred, long-tailed, predominantly grey species, with a short bill and strong legs and feet, and the sexes are alike in plumage. Some authorities, however, regard these characters as insufficient for separation from *Coracina*, and they retain the Ground Cuckoo-shrike in that genus, or accept *Pteropodocys* as having subgeneric rank, on the grounds that it may be more closely related to some *Coracina* taxa than are other, undisputed members of the latter. The two wattled cuckoo-shrikes from Africa are sometimes retained in *Campephaga*, but they are probably better separated in the genus *Lobotos* on the basis of their prominent facial wattles, colourful plumage and lack of strong sexual dimorphism. The two have discrete, non-overlapping ranges and are sometimes regarded as conspecific, but the male plumages are distinct, and it seems better to treat them as separate species forming a superspecies.

As described later (see Morphological Aspects), the cuckoo-shrikes treated as comprising the genus *Coracina* fall into two groups. The *Coracina* cuckoo-shrikes *sensu stricto* are larger, broader-billed and usually sexually monomorphic, whereas the cicadabirds, forming the "*Edolisoma* group", are smaller, more slender-billed and usually sexually dimorphic. A third group, containing two similarly small species, was once treated as constituting the genus *Volvocivora*; it, too, may be distinguishable and may form a link with the *Lalage* trillers, although it is sometimes included in a subgenus *Ceblepyris*. Efforts to determine whether these are natural groups, deserving generic recognition, are hampered by the limited amount of study that they have received and by disagreements among various authors, who have usually reviewed only part of the assemblage. Genetic comparisons may well indicate that the current taxonomy is in need of revision and that the division of *Coracina* into several genera may be appropriate.

Although there is still no general agreement on species limits within *Coracina*, the tendency in recent years has been to separate distinctive taxa formerly included in broad species. A good example is provided by *C. novaehollandiae*, in which were previously united many forms occurring from India east to Australia, in a somewhat arbitrary arrangement. This broad taxon has now been split into the Large Cuckoo-shrike (*Coracina macei*), the Javan Cuckoo-shrike (*Coracina javensis*), the Wallacean Cuckoo-shrike (*Coracina personata*) and the Black-faced Cuckoo-shrike (*Coracina novaehollandiae*); and all are included in a superspecies, along with the South Melanesian (*Coracina caledonica*), North Melanesian (*Coracina welchmani*), Buru (*Coracina fortis*), Moluccan (*Coracina atriceps*) and Slaty Cuckoo-shrikes (*Coracina schistacea*), and possibly also the Stout-billed Cuckoo-shrike (*Coracina caeruleogrisea*). The race *pollens* of the Wallacean Cuckoo-shrike was once considered a full species within this group. The four Solomon Islands races comprising *C. welchmani* have together been returned their former

In comparison with the forms called cuckoo-shrikes, cicadabirds tend to be smaller, lighter-billed and sexually dimorphic. Males are grey, much like cuckoo-shrikes, while females have brown, reddish or grey upperparts, barred underparts and complex face-patterns, as illustrated by this ***Slender-billed Cicadabird****. As their name suggests, they produce insect-like trills that differ widely from the more strident calls of cuckoo-shrikes. Given that* Coracina *embraces this level of morphological and vocal discontinuity, the results of future genetic analysis may prompt its subdivision into two or more genera, with cicadabirds returning to* Edolisoma.

[*Coracina tenuirostris grayi*, Halmahera, Indonesia. Photo: Morten Strange]

species status, separate from *C. caledonica*, on the bases of plumage, iris colour, voice, and habitat preferences.

Nevertheless, the separation of *C. macei* and *C. javensis* remains unresolved, with all eight subspecies of the former sometimes being placed in the latter. Crucial to this question is whether the Peninsular Malaysian subspecies *larutensis*, currently included in *C. macei*, should be included in *C. javensis*. It is assumed that the latter should incorporate only the populations of Java and Bali, but further research may dispute this. Moreover, differences in calls and morphology also suggest that the nominate race and the subspecies *layardi* of *C. macei* could together represent another, distinct species.

Confined to Africa, the genus *Campephaga* contains four species. Three of these are broadly allopatric and are included in a superspecies, but they present a complex taxonomic situation. The Black Cuckoo-shrike (*Campephaga flava*) and Petit's Cuckoo-shrike (*Campephaga petiti*) overlap in range in western Kenya, eastern DRCongo and north-western Angola, but they are largely separated by the latter's preference for true forest, the Black Cuckoo-shrike occurring in woodland and at forest edges. Females or young males from the Rwanda Rift and from Angola, however, have underparts that are strongly yellow, as in Petit's Cuckoo-shrike, but also well barred, as in the Black Cuckoo-shrike, suggesting that they are hybrids between the two. This appears to be a case of incomplete genetic isolation and, although the two species are sometimes considered conspecific, they are probably better treated as allospecies with marginal distributional overlap.

The relationship of the Red-shouldered Cuckoo-shrike (*Campephaga phoenicea*) to the Black Cuckoo-shrike is uncertain, and the two are sometimes considered conspecific on the basis of some assumed interbreeding. Their breeding ranges overlap only in south-western Ethiopia and western Kenya, and no males of intermediate appearance are known. On the other hand, some female Black Cuckoo-shrikes from central and eastern Kenya, outside the range of the Red-shouldered Cuckoo-shrike, have yellow in the tail that is intermediate in extent between the amounts exhibited by typical females of the two respective species, suggesting incomplete genetic isolation. In the areas where males and females of both species occur, all three female tail patterns are found, but differences are not sufficiently clearly defined to point to further intergradation. Where the Red-shouldered and Petit's Cuckoo-shrikes overlap geographically, in Cameroon and north-eastern DRCongo, they are ecologically separated and no interbreeding is suspected.

In the genus *Lalage*, the White-rumped Triller (*Lalage leucopygialis*) is often treated as a subspecies of the Pied Triller (*Lalage nigra*), and its systematic position is unclear. The two have non-overlapping ranges, and some authors regard them as forming a superspecies, which seems not unreasonable. On the basis of plumage characters, however, the White-rumped Triller would appear to be less close to the Pied Triller than is the White-shouldered Triller (*Lalage sueurii*), a form likewise treated as a

The ***Ground Cuckoo-shrike*** *is most peculiar. Not only is it the largest member of the family, but its deeply forked tail and terrestrial habits are unique. It lives in the arid interior of Australia, where it runs about on long legs in open acacia scrub, spinifex* (Triodia), *and grassy plains with scattered trees, its head bobbing back and forth all the while. Despite this suite of anomalous features, and its traditional placement in* Pteropodocys, *the Ground Cuckoo-shrike is patterned like many species of* Coracina, *and the two genera are sometimes merged.*

[*Pteropodocys maxima*, Meekatharra, Pilbara, Australia. Photo: Simon Nevill/ Lochman Transparencies]

The genus Lalage *is essentially Australasian in origin, but representatives have reached islands as far afield as the Nicobars, the Philippines, and Samoa. It contains twelve species of triller, the males of which are small and relatively slender-billed, boldly patterned in black and white on the upperparts, usually with prominent patches of white on the wings, rump and supercilium. The underparts are generally white, the exception being the* ***Rufous-bellied Triller****, which is almost entirely rufous below. Females are similar to males but duller, usually with some dark barring or scaling.*

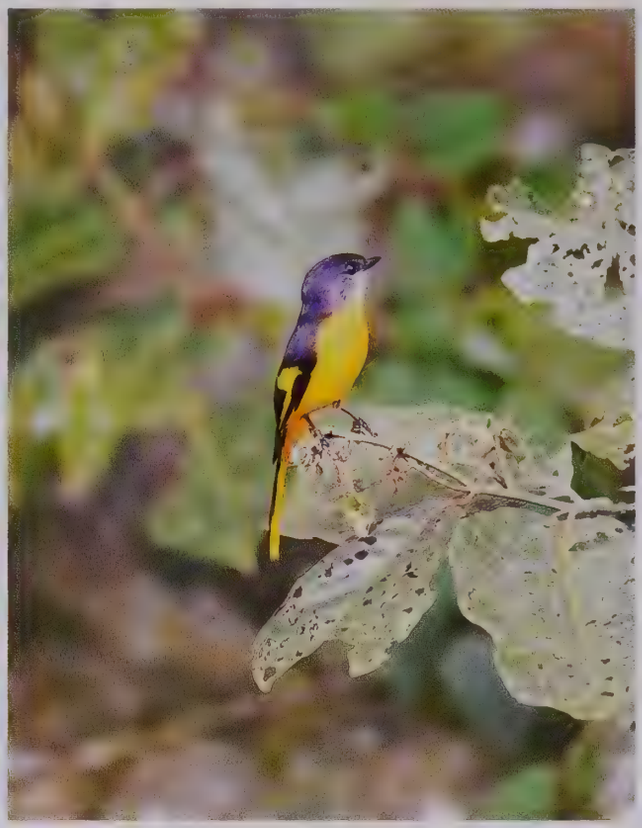
[*Lalage aurea*, Halmahera, Indonesia. Photo: A. Greensmith/ Ardea]

valid species herein. It is sometimes suggested that the White-shouldered and Pied Trillers might be conspecific, but they may occur sympatrically in Java; the situation there, however, is unclear and further study is required. On current information, it may make more sense to treat the White-shouldered Triller as forming a superspecies with the White-winged Triller (*Lalage tricolor*) of Australia and south-east New Guinea, and indeed these two are sometimes considered conspecific, although they are quite distinct in terms of plumage. Just to add to the confusion, the White-winged Triller is the only *Lalage* species in which the male is known to have an "eclipse" non-breeding plumage (see Morphological Aspects). The most aberrant species in the genus, the Samoan Triller (*Lalage sharpei*), which lacks sexual dimorphism and has a characteristically juvenile-type plumage, is sometimes placed in a monospecific genus, *Oscarornis*.

Swinhoe's Minivet (*Pericrocotus cantonensis*) is often considered conspecific with the Rosy Minivet (*Pericrocotus roseus*), primarily because, where the summer ranges of the two meet in southern Guangdong, in China, a small and, possibly, now stable population with mixed characters occurs in the valley of the River Sijiang, apparently as a result of interbreeding. This population was described as a separate species, *P. stanfordi*, in 1913, and it has also been regarded as representing a subspecies of the Rosy Minivet. There is, however, no sign that Swinhoes's and Rosy Minivets hybridize elsewhere in southern China in the region where their ranges closely approach or overlap one another, and the zone of occurrence of *stanfordi* is sufficiently restricted to suggest that the parent forms now behave as separate species. They are considered to form a superspecies.

For many years, the Long-tailed Minivet (*Pericrocotus ethologus*) was erroneously included with the sympatric Short-billed Minivet (*Pericrocotus brevirostris*). It was not until 1940 that E. Mayr distinguished between the two forms, which occur side by side over a wide range, from the eastern Himalayas to Myanmar, South-east Asia and southern China. The taxonomy at the subspecies level is still unclear, with some specimens not yet properly assigned. Further, the race *affinis* of the Short-billed Minivet is sometimes merged with the nominate race, a treatment which may be warranted but requires additional study. Some supposed *affinis* are apparently synonymous with the Long-tailed Minivet, and a more detailed review of specimen material is needed in order to resolve this matter.

Morphological Aspects



Members of the Campephagidae are small to medium-sized, mainly arboreal birds of conventional passerine form. The name "cuckoo-shrike" is normally applied to members of the genera *Coracina*, *Campephaga*, *Lobotos*, *Pteropodocys* and *Campochaera*, and these include the largest species in the family. The range of body sizes of these is, however, considerable. The Black-headed (*Coracina melanoptera*) and Lesser Cuckoo-shrikes (*Coracina fimbriata*) are 19–20 cm long and weigh only 24–36

The genus Campephaga *contains four closely related African species, all of which are slim with small bills and rather long, graduated tails. Sexual dichromatism is extreme, the males being glossy black with patches of colour at the gape and shoulder, like this* ***Black Cuckoo-shrike****. Females, meanwhile, are mostly olive-green above, yellow or white below, and prominently barred. Some of these species inhabit forests, others savanna, and they present a rather challenging taxonomic puzzle, with interbreeding reported in some regions, but not in others.*

[*Campephaga flava*, Nylsvley, Limpopo, South Africa. Photo: Warwick Tarboton]

The unassuming colour scheme of most campephagids is turned on its head in the Pericrocotus *minivets. This genus contains twelve diminutive upright-perching species, most of which are instantly recognizable by their vivid patterning and energetic charisma. Sexual dichromatism is usually acute, the scarlet or fiery orange of males being replaced by bright lemon-yellow in females. Like most of its congeners, the* ***Grey-chinned Minivet*** *has a long tail, a small bill, and feeble legs. Similarly, it lives in small, talkative groups which spend most of their time in the canopy.*

[*Pericrocotus solaris montanus*, Fraser's Hill, Malaysia. Photos: Morten Strange]

g, whereas, at the other extreme, the Ground Cuckoo-shrike is 31–38 cm long and weighs up to 155 g, and the South Melanesian Cuckoo-shrike can reach 180 g in weight. As is the case throughout the family, there is apparently little sexual dimorphism in size, but males tend to be slightly larger than females, For example, males of the Stout-billed Cuckoo-shrike weigh 127–170 g, while the females are 116–142 g in weight.

Cuckoo-shrikes have an elongated body and are typically quite slim. They have fairly long, pointed wings with ten primaries, and a moderately long, rounded or graduated tail with twelve rectrices. The Ground Cuckoo-shrike is unique in having a deeply forked tail. The bill is often rather stout, broad at the base, generally well hooked at the tip and strongly notched, and it is curved along the culmen. The nostrils are rounded, and are largely or completely obscured by the frontal feathering and the well-developed rictal bristles, an adaptation both to frugivory and to the consuming of hard-shelled insects. The tarsi are short, scutellated at the front and smooth at the rear, and the feet are characteristically coarsely scutellated, typically small and rather weak, and suited only for perching. There is one exception, the Ground Cuckoo-shrike, which has long, sturdy legs and long toes, characters adapted to its largely terrestrial existence.

The plumage is dense and soft. The shafts of the thickly downed feathers on the lower back and rump are often stiffened and enlarged, and are partly erectile and spine-like. These feathers may be puffed up over the back in display or defence, and they are easily shed, possibly as a defence mechanism, as occurs with the trogons (Trogonidae) and the pigeons (Columbidae). In addition, cuckoo-shrikes frequently carry powder-downs, hidden on the sides of the body and the back, and the uropygial glands, used for preening purposes, are much reduced.

Plumage patterns among the cuckoo-shrikes vary, from being virtually monomorphic to strongly sexually dimorphic. The Ground Cuckoo-shrike and, within the now enlarged genus *Coracina* (see Systematics), the *Coracina* species *sensu stricto* are relatively large and broad-billed, and tend towards monomorphism in plumage characters. Apart from the Cerulean Cuckoo-shrike (*Coracina temminckii*), which is predominantly greyish-blue, the males are largely grey to blackish, sometimes with black on the head; the underparts are sometimes paler grey or white, occasionally barred, and rarely, as demonstrated by the Black-bellied Cuckoo-shrike (*Coracina montana*), black. The females of these species are paler than the males, with less black on the head, and are often barred on the underparts. In contrast, the members of the "cicadabird group", formerly separated into the genus *Edolisoma*, are smaller, with a more slender bill, and are usually sexually dimorphic in plumage, with most males resembling "typical" *Coracina* species but the females having distinctive patterns of brown, reddish and grey upperparts and barred underparts. The male New Guinea Cuckoo-shrike (*Coracina melas*) is all black and the female entirely rufous-brown, while the females of the Mauritius (*Coracina typica*) and Reunion

When it comes to canopy flocks of passerines in tropical Asia, minivets usually steal the show. This photograph captures a typical view overhead: a couple of birds move into some bare twigs in the early light. One of them, a ***Scarlet Minivet****, takes off to reveal the dazzling patches of colour in its wings and tail, and the other goes unwatched and unidentified. Before they vacate a tree, minivets often perch prominently right on top of the canopy. After they set off for their chosen destination, their flight is direct but fluttery, with the long, graduated tail held partially open.*

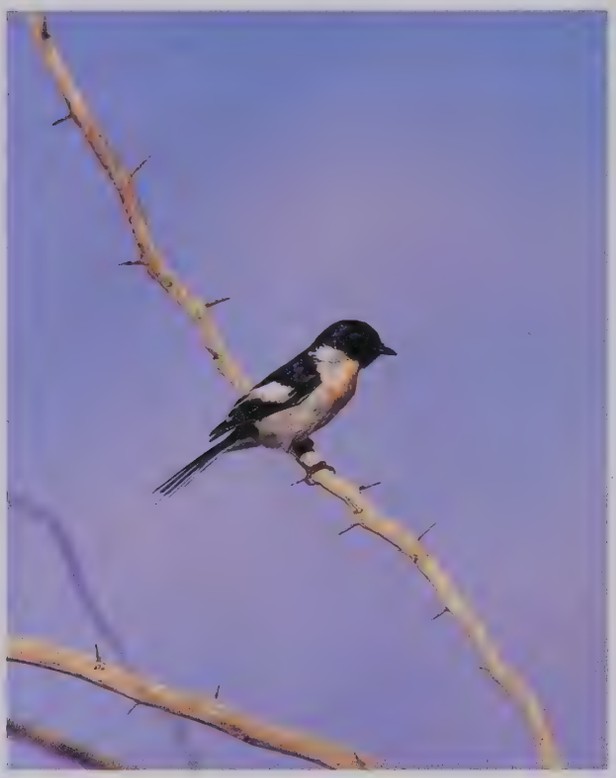
[*Pericrocotus flammeus andamanensis*, Havelock Island, Andamans. Photo: Konrad Wothe]

Most minivets are birds of humid montane forests, but a few inhabit drier or more stunted formations right down to sea-level, including strand forest and mangroves. Others, like the ***Short-billed Minivet****, are partial to stands of conifers or montane pine forests, and this species ascends to nearly 3000 m in summer. Only in the 1940s was it realized that the then-accepted species in fact comprised two morphologically similar, yet broadly sympatric species, one of which was redaubed the Long-tailed Minivet* (Pericrocotus ethologus) *—which just goes to prove that not all "cryptic species" are dreary to look at!*

[*Pericrocotus brevirostris*, Bhutan. Photo: Roland Seitre]

Cuckoo-shrikes (*Coracina newtoni*) have brown upperparts and, respectively, chestnut or barred underparts.

The four *Coracina* species of Africa are medium-sized, with a rather stout bill. They have a tail of medium length and almost square-ended, the outermost feathers being slightly shorter than the rest. In three species the plumage is grey, or grey and white, but that of the Blue Cuckoo-shrike (*Coracina azurea*) is almost entirely brilliant glossy blue. The sexes are similar, the females being only slightly less boldly patterned and coloured than the males. The other African cuckoo-shrikes are very different. The four *Campephaga* species are slim, with a relatively small bill and a rather long, graduated tail, and they exhibit very strong sexual dimorphism in plumage. The males are predominantly glossy black, with orange or yellow gape wattles, while the Red-shouldered Cuckoo-shrike has red or orange lesser and median upperwing-coverts, and the Black Cuckoo-shrike often has yellow lesser coverts. The females in this genus are mostly olive-green on the upperparts and yellow or white on the underparts, and those of all species except Petit's Cuckoo-shrike have pronounced dark barring on the underparts and, variably, on the upperparts. The two wattled cuckoo-shrikes, constituting the genus *Lobotos*, have a smaller bill and very prominent orange to yellow wattles below the eye; their plumage is predominantly green above and yellow or orange below, while the head is blackish. The sexes are similar, but the female is duller, with smaller wattles.



Farther east, the Golden Cuckoo-shrike, confined to New Guinea, is a small species with a small bill and much yellow in the plumage. The female has much the same coloration and pattern as the male, but in a washed-out version.

Immature and juvenile plumages are not described for many species in the family. Moreover, plumage sequences are sometimes difficult to interpret, especially for African species, because no proper distinction is made in published descriptions between the first plumage, referred to as the "juvenile", and that acquired at the post-juvenile moult, the "immature" plumage. Nevertheless, a characteristic of the Campephagidae appears to be that the immature plumage resembles that of the adult female. The juvenile plumage pattern is often basically similar to that of the immature, but duller, usually with pale and, in some cases, also dark scaling on the upperparts, and often with dark bars or scales on the underparts; the remiges and rectrices may have pale edges and, sometimes, pale tips. The Stout-billed Cuckoo-shrike is unusual in that the newly fledged young are predominantly whitish-grey, with some dark grey on the head, breast and wings, and with whitish upperwing-coverts.

The trillers in the genus *Lalage* are smaller birds, with relatively long legs, a rather short, slender bill, and a medium-long tail which varies, according to species, from almost square-ended to slightly graduated. The plumage is dense and soft, and the rump feathers do not have spiny shafts. In males, the head and upperparts are boldly patterned in black and white, usually with a prominent white wingbar and a pale rump, and often with a white superciliary stripe. The underparts are generally white, but the male Rufous-bellied Triller (*Lalage aurea*) is almost entirely rufous below. The females are typically patterned like the males but are duller, the black of the upperparts being replaced by brown to grey, and those of most species show some dark barring or scaling on the underparts. The two triller species which inhabit oceanic islands at the extreme eastern limit of the family's range differ quite markedly in plumage from their congeners. The first of these, the Polynesian Triller (*Lalage maculosa*), is very variable, the males of several of its 16 island subspecies being brown, rather than black, and some having dark barring and a rufous wash on the underparts. The Samoan Triller, which, with a length of 13 cm, is one of the smallest species in the family, has entirely brown upperparts and barred underparts, has virtually lost all white patterning in the wings, and is sexually monomorphic.

Of particular interest is the White-winged Triller of Australia and south-east New Guinea. This is the only campephagid in which the male is known to have two plumages yearly. Its black-and-white breeding plumage is replaced in the post-breeding moult by a so-called "eclipse" plumage, which resembles that of the brown female except that the remiges and rectrices remain black. The White-shouldered Triller, with which the White-winged Triller is often considered conspecific (see Systematics), does not possess this eclipse plumage. It has been suggested that the male Long-tailed Triller (*Lalage leucopyga*) may also have an eclipse plumage, but this is unconfirmed.

The two flycatcher-shrikes in the genus *Hemipus* have a relatively flat bill, which is very much depressed and is comparatively wide at the base. The rictal bristles are small, and the nostrils are more or less hidden by hairs. The tail is narrow and graduated, the wings fairly long and pointed, and the legs and feet

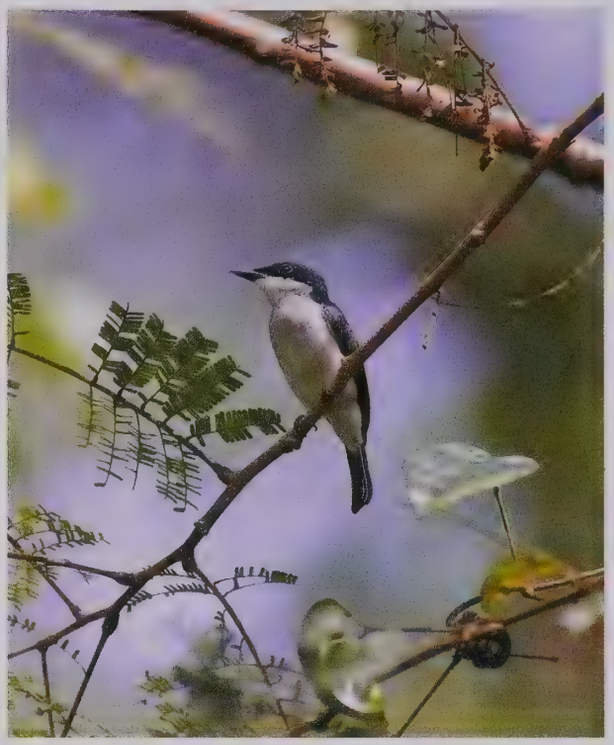
*The **White-bellied Minivet** is an outlier in the genus* Pericrocotus, *almost completely lacking the rich carotenoid pigmentation of its relatives. It is essentially black above and white below, with a reddish flush on the chest; in other words, it is somewhat* Saxicola*-like in pattern, if not behaviour. Not only is it exceptional in inhabiting low-stature dry forest, shrubland and semi-desert in the Indian Subcontinent, but its undulating flight is also unusual. Its affinities deserve further investigation, as does the taxonomic status of the race* albifrons, *a poorly known but highly divergent form from the basin of the Irrawaddy, in Myanmar.*

[*Pericrocotus erythropygius erythropygius*, Kachchh, Gujarat, India. Photo: Otto Pfister]

small; the rump feathers do not have spiny shafts. Like the trillers, the flycatcher-shrikes are sexually dimorphic in plumage. The males are black and white above, although the Black-winged Flycatcher-shrike (*Hemipus hirundinaceus*) lacks a white wingbar, and greyish-white below, while the females have the black replaced by grey or brown. In the race *leggei* of the Bar-winged Flycatcher-shrike (*Hemipus picatus*), however, the female is black and white, like the male.

Although bearing a superficial resemblance in plumage pattern to the true shrikes of the family Laniidae, the two wood-shrike species in the genus *Tephrodornis* differ from them in having a smaller head, a longer bill, a short tail, soft plumage and smaller legs and feet. The tail is square-ended, and the wings are moderately long and rather rounded. The very stout bill is about three-quarters the length of the head, is quite wide at the base, and is strongly hooked and notched. The nasal bristles are very numerous, entirely concealing the nostrils. The rump feathers are very ample, but are soft, and not spinous. Both species have greyish-brown upperparts, a black mask, white on the rump, and greyish-white underparts, and the Common Wood-shrike (*Tephrodornis pondicerianus*) also has a white supercilium. The sexes are more or less alike, the female being rather duller than the male, with a browner mask.

The smallest members of the family are the twelve minivets that make up the genus *Pericrocotus*. They are about the size of a wagtail (*Motacilla*), with moderately long wings and a long and steeply graduated tail. Although the Small Minivet (*Pericrocotus cinnamomeus*) is 16 cm long, its tail accounts for about half of its length, and the bird weighs only 6–12 g. The bill of minivets is relatively short, moderately broad at the base, and rather high, with a slightly curved culmen. The nostrils are partly concealed by frontal plumes, and the rictal bristles are few and insignificant. The legs and feet are short and rather feeble, and the claws are well curved. The shafts of the rump feathers are spiny, as in the cuckoo-shrikes. Most minivet species have brilliantly coloured plumage, the males being of a striking red and black, and the females yellow or orange and blackish to grey.



Moult in the Campephagidae is imperfectly known, but sufficient information is available to suggest that the typical pattern in the family is of a complete post-breeding moult and a partial pre-breeding moult. In the complete moult, the primaries are shed descendantly over a period ranging from two months to five months, the rectrices are usually moulted centrifugally, usually at the same time as the primaries, and moult of the head and body plumage commonly begins before the primary moult starts and continues after primary moult is complete.

The young of most species appear to undergo a partial post-juvenile moult, involving all or most of the body feathers, the marginal wing-coverts, most or all the median coverts, some or all the greater secondary coverts, and sometimes some tertials and/or rectrices. This post-juvenile moult usually results in the acquisition of a female-like immature plumage, and is followed by a partial pre-breeding moult in which most species acquire an adult-type plumage, although some do not gain full adult body plumage until after the first post-breeding moult. Thus, the Mauritius Cuckoo-shrike loses its juvenile body plumage within about

The two wood-shrikes in the genus Tephrodornis *are also placed with the Campephagidae. Both are relatively small, short-tailed and prominently hook-billed, with a pad of bristly hairs concealing the nostrils. They are grey, with paler rumps, darker masks, and, in the case of the **Common Wood-shrike**, a white supercilium. Both inhabit a variety of wooded formations, including tall scrub, bamboo, deciduous forest, and open evergreen forest, where they are a regular, if not particularly conspicuous, component of canopy flocks.*

[*Tephrodornis pondicerianus*, Ranthambore Sanctuary, Rajasthan, India. Photo: Gertrud & Helmut Denzau]

Another anomalous campephagid duo is made up of the flycatcher-shrikes in the genus Hemipus. *Of these, the* ***Black-winged Flycatcher-shrike*** *is typically pied, with black upperparts and white underparts. In females, the black is replaced with grey or brown. Both species have an odd bill, broad-based and laterally compressed, as befits their foraging tactic. In stance and pattern the males are reminiscent of some* Myiagra *(Monarchidae) or* Ficedula *(Muscicapidae) flycatchers, and likewise they sally to catch flying insects. Flycatcher-shrikes, however, often accompany mixed-species flocks in the canopy.*

[*Hemipus hirundinaceus*, Panti Forest, Malaysia. Photo: Morten Strange]

two months, attaining a plumage like that of the adult female, although some males develop partly adult whitish underparts. Individuals attain complete adult plumage only with the first complete post-breeding moult, more than a year after hatching.

The Ashy Minivet is unusual in having two complete moults in each year.

Habitat

The principal or, often, the only habitat exploited by 73 of the 86 species in the family is forest. Together, these occupy a wide range of forest types, including tropical or subtropical rainforest, swamp-forest, moss forest, vine forest, bamboo forest, monsoon forest, eucalypt (*Eucalyptus*) forest, deciduous forest, including oak (*Quercus*) forest, and pine (*Pinus*) forest. A few species, such as the New Caledonian Cuckoo-shrike (*Coracina analis*), the Hooded Cuckoo-shrike (*Coracina longicauda*) and the Golden Cuckoo-shrike, are restricted to primary forest, but the majority are apparently able also to utilize, at least to a limited extent, secondary forest, forest edges and the edges of clearings, selectively logged forest and other degraded forest habitats. In Kibale, Uganda, Petit's Cuckoo-shrike has even been recorded as commonest in logged areas with dense undergrowth and a sparse canopy, but this is exceptional. Riparian or gallery forest and forest patches are also occupied by some species, while many occur in mangroves as well. Almost all species are predominantly or exclusively arboreal, and many are found mainly in the upper levels or canopy of tall trees.

Many of the primarily forest-dwelling species can sometimes be found in other habitat types, such as woodland, wooded cultivation and watercourses, evergreen thickets, orchards and even savanna. Some may forage in artificially created or modified habitats, such as old or overgrown plantations of rubber, coconut, teak (*Tectona*), pine or wattle (*Acacia*), and even in parks, avenues and suburban gardens.

A few species are adapted to woodland or more lightly timbered habitats, rather than true forest. On Sulawesi, for example, the widespread and common White-rumped Cuckoo-shrike (*Coracina leucopygia*) exploits open wooded areas, lightly wooded cultivation, secondary woodland and scrub with trees. In Africa, the White-breasted Cuckoo-shrike (*Coracina pectoralis*) occurs in acacia (*Acacia*) savanna north of the equator, whereas in southern Africa it inhabits tall, broadleaf woodland such as brachystegia (*Brachystegia*), *Baikiaea* and mopane (*Colophospermum mopane*). The White-winged Triller in Australia is found in a wide range of lightly timbered habitats with a sparse, open shrub layer and grassy ground cover, particularly in dry, open eucalypt woodland, as well as in sparsely wooded farmland. It does not occur in heavily forested areas, except where clearing has taken place. In arid and semi-arid zones, it is often attracted to flowering shrubs and trees, and on migration it occurs in open country with trees, and sometimes in coastal casuarina (*Casuarina*) groves.

More open, less wooded areas are favoured by another Australian campephagid, the Ground Cuckoo-shrike. This species is

As with most aspects of their natural history, there are few details on record about the general habits of campephagids, and little can be said of their comfort behaviour until detailed field studies are undertaken. They are known to sunbathe in typical fashion, either on branches or on the ground, as this ***Black-faced Cuckoo-shrike*** *attests. In raising its sunlit feathers it shows off one feature that binds the Campephagidae as a family: the long plush feathering of the rump and lower back. Interestingly, in* Coracina *at least, these feathers have spiny shafts and sharp tips, and come away easily when the bird is alarmed.*

[*Coracina novaehollandiae*, Jervis Bay, New South Wales, Australia. Photo: Graeme Chapman]

Many Coracina *species advertise their presence with far-carrying and distinctive vocalizations. These are given either in flight, or while perched prominently at the tops of trees, with such regularity that they are a familiar background noise in many Asian and Australasian forests. The* ***Large Cuckoo-shrike****, for example, produces loud parrot-like screeches as well as chuckling notes, though calls do vary regionally. Most campephagid vocalizations seem to be trills, churrs, chatters, whistles or squawks of some sort, often in repetitive series. They are not known to produce complex songs.*

[*Coracina macei larutensis*, Fraser's Hill, Malaysia. Photo: Morten Strange]

often found in dry places, including acacia scrub and spinifex (*Triodia*), and grassy plains with scattered trees or shrubs. Although its preferred habitats have little or no ground cover, they do usually contain at least scattered trees. The extreme example of the utilization of very dry habitats with no trees is presented by the White-bellied Minivet (*Pericrocotus erythropygius*) in the Indian Subcontinent. This fascinating bird ranges from savanna to dry thorn-scrub, grassland, dry cultivation, hedgerows, rocky scrub-covered slopes and, occasionally, semi-desert.

Some campephagid species may be regarded more as habitat generalists, exploiting a very wide range of vegetation types, including forest, woodland, savanna and cultivated areas. The White-bellied Cuckoo-shrike (*Coracina papuensis*), for instance, is found in woodland, savanna, many types of forest, secondary growth, mangroves, coconut, teak and *Araucaria* pine plantations, wooded farmlands and suburban gardens. In south and Southeast Asia, the widespread Large Cuckoo-shrike, as well as inhabiting open, light and secondary forest, including those of teak, pine and oak, also frequents savanna, open and cultivated areas with scattered trees, and gardens. Likewise, the Black Cuckoo-shrike in Africa can occur in virtually any woodland or forest habitat, and less commonly in savanna, scrub, semi-arid bush, gardens and exotic plantations. In areas of overlap with more forest-dependent species, it is more restricted to forest edge, woodland and savanna. Among the minivets, the Small Minivet utilizes forest, woodland, mangroves, thorn-forest, strand woodland, casuarinas, scrub, orchards and other cultivated lands, preferring more open wooded habitats than those used by most of its congeners. Similarly, the Common Wood-shrike occurs in open forest, dry deciduous forest, secondary growth, bamboo forest, woodland, scrub, orchards, gardens, hedgerows, and dry open country with scattered trees. Among the trillers, the White-shouldered Triller is found in woodland, savanna, open forest, scrub, mangroves, overgrown cultivation, including rice fields, swamps, gardens and near human habitations.

Migratory species may tolerate a wider range of habitats during passage or in the non-breeding areas, often entering degraded or cultivated habitats, sometimes near human habitations. Thus, the Black-winged Cuckoo-shrike (*Coracina melaschistos*), which inhabits mainly deciduous forest, forest edge, groves and bamboo jungle, can be found in winter also in gardens, abandoned cultivation, open areas and woodland. The Ashy Minivet, a long-distance migrant, breeds in a broad variety of habitats, including evergreen and deciduous forests, secondary growth, woodland and scattered trees, while on passage and in winter it also frequents mangroves, mixed peatswamp-forest, beach vegetation, casuarinas, plantations, open country and even towns. Its relative, the Long-tailed Minivet, inhabits a wide range of open forest types, including both broadleaf and pine forests, and also occurs, especially in the non-breeding season, in largely deforested areas, groves, wooded cultivation and roadside avenues. The Slender-billed Cicadabird (*Coracina tenuirostris*) occupies a wide range of tropical and temperate forests, but migrants in New Guinea are absent from the forest interior, except on is-

Minivets give simple trilling, twittering or piercing notes when foraging or in flight, and these usually provide the best means of locating flocks. The same calls are sometimes given in a song-like series, but the distinction between a contact function and a sexual or territorial function is rather difficult to draw in campephagids, hampering the use of voice in determining species limits. Throughout most of its range the ***Scarlet Minivet*** *gives a series of whistles, but in the Himalayan form* speciosus *this is replaced with a single lower-pitched upslurred note. More research is needed to clarify the phylogenetic significance of this type of geographical variation.*

[*Pericrocotus flammeus andamanensis*, Andaman Islands. Photo: Otto Pfister]

lands, and prefer instead to keep to forest edges, secondary growth, savanna and mangroves.

The great majority of species occur at low to medium altitudes. Over half of them, approximately 45 species, including the two wattled cuckoo-shrikes and both wood-shrike species, are found from sea-level up to about 1500 m. A few of these primarily lowland campephagids are known to ascend to about 2000 m, but the number of true montane species in the family is small. In the genus *Coracina*, only four resident species are regarded as exclusively birds of montane forest. These are the Black-bellied and Hooded Cuckoo-shrikes of the mountains of New Guinea, where the latter species occasionally reaches 3700 m, the Pygmy Cuckoo-shrike (*Coracina abbotti*) of Sulawesi and McGregor's Cuckoo-shrike (*Coracina mcgregori*) of the Philippines. In the Afrotropics, the forest-dwelling Grey Cuckoo-shrike (*Coracina caesia*) has a very wide altitudinal range, typically occurring above 1000 m in West Africa and at 1500–3000 m in Central and East Africa, but also, exceptionally, near sea-level in Cameroon and Kenya. Farther south, it regularly comes down to sea-level in South Africa. This species is an altitudinal migrant in some parts of its range, descending to lower levels after breeding. Grauer's Cuckoo-shrike (*Coracina graueri*) inhabits African montane and transitional forest, from 1150 m to 1900 m; it is mainly allopatric or parapatric with the Grey Cuckoo-shrike, which typically occurs at higher altitudes.

Two of the four *Campephaga* species also occur typically at higher elevations in Africa. Petit's Cuckoo-shrike inhabits forest mostly at 1000–2000 m, while the wide-ranging and habitat-generalist Black Cuckoo-shrike breeds mainly from 900 m to 2000 m in Central and East Africa, but near sea-level in the Cape, at the southern extreme of the continent. It is a migrant, and in some areas, as with the Grey Cuckoo-shrike, it is present at lower elevations outside the breeding season. In addition, the Purple-throated Cuckoo-shrike (*Campephaga quiscalina*), although mainly a lowland-forest species, occurs in Kenya only at 1500–2500 m.

The minivets include several species that are typically mountain-dwellers. The Grey-chinned Minivet (*Pericrocotus solaris*) is recorded from 600 m to 3050 m, the Long-tailed Minivet at 900–3650 m, rarely to 3965 m, and the Short-billed Minivet and Sunda Minivet (*Pericrocotus miniatus*) up to about 2700 m. The first two of these species are altitudinal migrants, and the Long-tailed Minivet descends as low as 245 m in winter. The Sunda Minivet is apparently sedentary, and it is therefore a true montane-habitat specialist.

Many other migratory campephagids often descend to lower elevations in the non-breeding season, and this behaviour typically occurs among species breeding at high elevations in south Asia. This is enlarged upon later (see Movements).

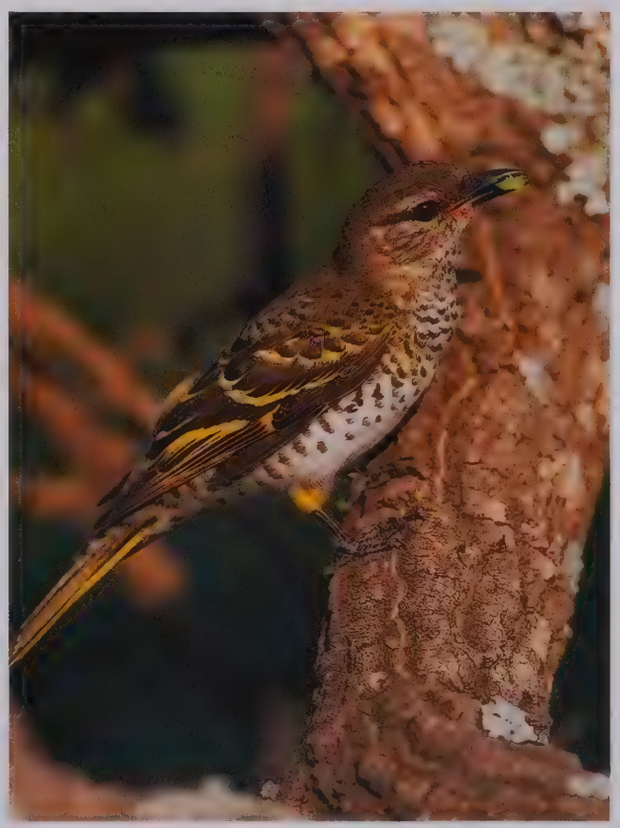
General Habits

Almost all cuckoo-shrikes are arboreal, and most species in the genera *Coracina*, *Campephaga* and *Lalage* occur singly, in pairs, or in small groups of up to about five individuals that are often family parties. Many members of the Campephagidae, such as the Red-shouldered Cuckoo-shrike, the Western Wattled Cuckoo-shrike (*Lobotos lobatus*) and the Slender-billed Cicadabird, are often difficult to locate, as they are unobtrusive and quite silent as they move around among the foliage. Others, however, although of similar habits, have loud calls that draw attention to their presence. Examples of these are the Mauritius Cuckoo-shrike, which is secretive but may be located by its melodic trill and harsh call note, and the Hooded Cuckoo-shrike, which moves slowly through the trees as a group, calling frequently. Other species betray their presence more readily. This is especially true of the frugivorous ones such as the Golden Cuckoo-shrike, which forages in active and noisy groups, and the Barred Cuckoo-shrike (*Coracina lineata*). The latter occurs not only in small groups, but also in flocks of up to 20, and occasionally up to 40, individuals; it forages actively, while uttering a pleasant chattering call. Depending on the species, trillers may be either active or unobtrusive, but their calls usually draw attention to their presence.

Flycatcher-shrikes and wood-shrikes sometimes occur in small flocks, and are active and not usually difficult to locate. By way of comparison, flocks of minivets, with their bright colours, restless behaviour and musical contact calls, are much more obvious as they flit from tree to tree. Not all minivet species, however, behave in this way. The Rosy Minivet is rather more sluggish, often sitting still on the tops of trees, while the Short-billed Minivet typically lives in pairs, and the White-bellied Minivet is less arboreal and forms only small parties.

The cuckoo-shrikes and their relatives are fundamentally insectivorous, consuming a large amount and broad variety of invertebrate prey. Bulky campephagids, such as the ***Moluccan Cuckoo-shrike****, tend to be fairly ponderous and methodical, searching for arthropods by hopping or walking along trunks and branches, and diligently examining foliage, creepers and vines. They often eat a great many caterpillars, earning them the name "caterpillar-birds" in some regions, but they also catch larger animals, including small vertebrates.*

[*Coracina atriceps magnirostris*, Halmahera, Indonesia. Photo: Morten Strange/ NHPA]



Like other Lalage *species, the* ***White-winged Triller*** *eats a wide variety of insects, including orthopterans, mantids, hymenopterans, bugs and beetles, often dropping down to glean these from the ground. It also visits shrubs and trees to eat fruit, flowers, buds, seeds and nectar, although it is difficult to tell which of these are the real targets here. Most campephagids are relatively solitary, or live in small groups, but some trillers have been noted consorting in flocks of up to 70 in the non-breeding season.*

[*Lalage tricolor*, Mitchell Plateau, Kimberleys, Western Australia. Photo: Jiri Lochman/ Lochman Transparencies]

Flocking behaviour is much more prevalent outside the breeding season, when many species associate in monospecific parties or larger flocks. The White-bellied Cuckoo-shrike, for example, associates in groups of up to twelve or so individuals at this time. More strikingly, the Black-faced Cuckoo-shrike occurs in flocks of 50 or more birds, and Australian migrants of this species in Papua New Guinea are conspicuous and highly gregarious, with roosting flocks of 100 or more recorded in southern areas. Similarly, the White-shouldered and White-winged Trillers form flocks containing up to 70 individuals, while the Large Wood-shrike (*Tephrodornis virgatus*) can be observed in flocks of up to 30 in the non-breeding period.

Throughout the family's range, many campephagids regularly associate with mixed-species foraging flocks in forest or woodland, from low to high altitudes. This behaviour is recorded for members of all genera except the monotypic *Pteropodocys* and *Campochaera*, and is well documented in Asia and Australia, while all the African cuckoo-shrikes, comprising ten species in the genera *Coracina*, *Campephaga* and *Lobotos*, are known to join such flocks. In a New Guinea study, J. M. Diamond found that one type of foraging association, which he termed the "brown and black flock", was distinctive in that member species converged on two alternative colours, rather than on one, and that the flock retained its character through many geographical and altitudinal changes of species composition. The flocks included 35 species and were led by the Rufous Babbler (*Pomatostomus isidorei*) or, in its absence, by one of five pitohui (*Pitohui*) species, all of which have rusty-brown or blackish plumage. Flock-members were predominantly brown, or black to grey. The followers included seven cuckoo-shrikes, at least one species being recorded in many flocks and all seven in at least one flock. All of the cuckoo-shrike species occurring within the altitudinal range of the flocks, 0–1700 m, were represented. They were the Black-shouldered Cicadabird (*Coracina incerta*) and the New Guinea, Barred, Grey-headed (*Coracina schisticeps*), Black-bellied, Stout-billed and Boyer's Cuckoo-shrikes (*Coracina boyeri*).

As well as bearing a superficial resemblance to cuckoos in their plumage and general appearance, the larger cuckoo-shrikes also have an undulating, cuckoo-like flight, in which flapping to gain height is alternated with gliding on stiffly downward-held wings. The flight of some species is rather slow, that of the Stout-billed Cuckoo-shrike appearing somewhat laboured, but the Black-faced Cuckoo-shrike has a vigorous flight with deep wingbeats, and it sometimes glides or dives with the wings closed. Boyer's Cuckoo-shrike has a bouncing, almost hesitant flight, while the Moluccan Cuckoo-shrike executes distinctive, rapid wingbeats. The trillers and the wood-shrikes also have an undulating flight, and in the air trillers look small-headed, with broad, rounded wings. Although the minivets generally have a direct flight, during which the long, graduated tail is often held spread,

In the endemic African genera of Campephaga *and* Lobotos, *insects are the principal food, with lepidopteran larvae forming a large part of the diet of all six species. The urticating species, with poisonous hairs, are usually rubbed vigorously on branches before being consumed. As well as juicy caterpillars, this female* ***Black Cuckoo-shrike*** *is partial to spiders, ants and alate termites, which it hunts at post-rain hatchings. Pairs of cuckoo-shrikes are a common sight in African woodlands, where they spend much of their time following mixed-species flocks of foraging insectivores.*

[*Campephaga flava*, Nylsvley, Limpopo, South Africa. Photo: Warwick Tarboton]

Fruit makes up a large part of the diet in at least 20 Coracina *species, and for some, including the* ***Barred Cuckoo-shrike****, it is the dominant component. This widespread taxon consumes many types of small berries and other fruit, such as* Ficus, Calamus, Terminalia *and* Alphitonia, *gathering in small parties to harvest the abundant food supply at fruiting trees, often alongside other frugivores. In comparison, insects are of minor significance, but prey such as caterpillars and beetles are taken opportunistically.*

[*Coracina lineata lineata*, Kuranda, North Queensland, Australia. Photo: Len Robinson/ FLPA]

the White-bellied and Ashy Minivets fly more in the manner of wagtails, with a few flaps followed by a dipping glide.

When foraging and moving around in trees, many species are quite slow and deliberate in their actions, making long hops and frequent pauses, while some walk and run along branches. Ground Cuckoo-shrikes, aided by their long legs, run freely on the ground, with the head bobbing backwards and forwards like that of a pigeon, and they often leap up to catch insects. When foraging terrestrially, the Black-headed Cuckoo-shrike makes long hops in the manner of a thrush. Some cuckoo-shrikes in the genera *Coracina* and *Campephaga* have a habit of perching motionless on a branch, often in an upright stance and sometimes for long periods; the function of this behaviour is not clear, although it certainly makes the birds very difficult to locate. Many members of the family often alight on an exposed perch, such as a high branch of a dead tree, a telegraph pole, a post or even a wire, and they may sit quietly for some time in such an open situation. Further, some, such as the Cerulean Cuckoo-shrike, call and sing from high, bare branches, and the trillers, too, often perch on exposed branches and utter calls from them. When perched, minivets have an upright posture and frequently flirt the wings and tail. During foraging, they sometimes perch on the tops of trees before flying on.

Some of the larger *Coracina* species have the habit of shuffling or flicking their wings on alighting and when perched, and this action, sometimes described as "nervous-looking", is a recognized field character. The same behaviour is recorded for the Ground Cuckoo-shrike, too. The North Melanesian Cuckoo-shrike also shuffles its wings when foraging, while the Hooded Cuckoo-shrike is said to flick its wings before flying, but not when landing. Among the African species, the Grey Cuckoo-shrike gives occasional flicks of its wings when moving around, while the behaviour is also recorded for the genus *Campephaga*, the Black Cuckoo-shrike often flicking its wings when perched.

A feature peculiar to cuckoo-shrikes is the presence of long, erectile feathers on the lower back and rump (see Morphology). These may be erected during display or when the bird is alarmed. The Black Cuckoo-shrike, for example, when disturbed at the nest, raises these feathers and directs its rounded-looking back towards the source of the danger. A brooding individual will also erect these feathers in the presence of a predator, when the head and tail are depressed and the raised rump feathering makes the bird look like a bump on the branch where the tiny nest is placed. It has also been suggested that these feathers, which have spinescent tips, might deter a small predator that attempted to grab the bird from behind.

All members of the family are territorial when breeding. Members of some resident populations may be territorial throughout the year, even if others of the same species are migratory and exhibit only seasonal territorial behaviour. Agonistic behaviour towards conspecifics and other bird species is well known among

The ***Varied Triller*** *is not much of a socialite: pairs or trios forage surreptitiously in tree canopies, but they rarely associate with other species and are often quite difficult to find. As well as insects, the species eats a great deal of fruit, berries and seeds. By repute, it is particularly attracted to the smaller varieties of figs* (Ficus), *and this photograph does nothing to detract from that theory.*

[*Lalage leucomela rufiventris*, Kakadu National Park, Northern Territory, Australia. Photo: Stuart Miller/ Lochman Transparencies]

Pair-territoriality is the norm for most campephagids during the breeding season, and several resident species appear to defend these territories all year round. This seems to be the case for the ***Madagascar Cuckoo-shrike****, a species that occurs in its namesake island and in the nearby Comoros. Like other* Coracina *species, it builds a small saucer-shaped nest from fine plant fibres, placing this on top of a branch or fork, and decorating the exterior with lichen, moss or pieces of bark, presumably for camouflage.*

[*Coracina cinerea*, Madagascar. Photo: Dominique Halleux/Bios]

breeding campephagids, but it has not been described outside the breeding season. An interesting exception to the general picture is provided by the Ground Cuckoo-shrike. This Australian campephagid is permanently group-territorial and, when the group is foraging on the ground, one individual usually perches in a nearby tree, possibly acting as a lookout.

There is no evidence that any species in the family is anything other than strictly diurnal in its activity. The Black-faced Cuckoo-shrike, for instance, is active from a few minutes after sunrise until about 15 minutes before sunset, and this is probably fairly typical for the family as a whole. Little is known about the roosting behaviour of the Campephagidae. For the few species for which some information is available, roosting takes place singly, in pairs or in small groups in trees, at sunset. In Australia, at least 36 Barred Cuckoo-shrikes were once seen at roost together in a single tree, and migratory species are known to roost in flocks in trees during the non-breeding-season. A flock of Black-faced Cuckoo-shrikes was observed as it circled an area, in almost complete silence, towards dusk; the flock often divided, and individuals alighted in trees before rising and rejoining the flock, which finally settled for the night in the trees.

Very little is known about the comfort activities of members of this family, and allopreening has not been recorded for any of its species. There are, however, several observations of bathing. The Black-faced Cuckoo-shrike bathes in rain, and flutters in wet foliage during rain, while parties of Large Wood-shrikes bathe in the evening in a pool or stream, by swooping down like drongos (Dicruridae) and dipping while on the wing. Sun-bathing is probably widespread in the family, and has been recorded, for example, in the White-winged Triller. This species lies with the body lowered on a horizontal branch, the tail towards the sun, the wings and tail fully spread, and the plumage of the head and upperparts slightly raised. It has also been seen to sun-bathe on the ground, with the feathers fluffed up. During hot weather, temperature regulation is achieved by panting.

Voice

Most cuckoo-shrikes tend to be unobtrusive and quite silent when foraging. Many, however, have loud contact or display calls that are uttered frequently by members of pairs, parties or flocks in flight from tree to tree, and such calls are often characteristic sounds of the forests in which these species occur.

Campephagid songs and territorial calls are simple, often loud and frequently repeated, and, in the case of many species, are apparently given largely or exclusively by the male. Vocalizations consist typically of trills, churrs, chatters, whistles or squawks, some calls being nasal or metallic in quality and others resembling insect sounds. The cicadabirds in the genus *Coracina* are aptly named, as most species have songs reminiscent of the loud mechanical noises produced by the large homopteran bugs known as cicadas (Cicadidae). For example, the Sumba Cicadabird (*Coracina dohertyi*) has a three-note, grating cicada-like song, while the Sulawesi Cicadabird (*Coracina morio*) produces a slow sequence of cicada-like buzzy, nasal, ringing notes alternating with a clear, descending whistle, and the Black-shouldered Cicadabird emits a series of 5–30 disyllabic, buzzing notes. Cicadabirds are generally more secretive than are other *Coracina* cuckoo-shrikes, and their calls are often the best clue to their presence. The Large Cuckoo-shrike is unusual in that its song is a quaint, rarely heard melodious warble, but its calls are loud and screeching and reminiscent of those made by a parrot (Psittacidae). The Hooded Cuckoo-shrike also gives a loud, parrot-like squeal and other harsh, jangling and rasping notes, while the jumbled song of the White-bellied Cuckoo-shrike is said to be suggestive of the sound made by wind chimes.

In the strictly Afrotropical genera, the two wattled cuckoo-shrikes in *Lobotos* are mainly silent and inconspicuous, with "zit" or "tsik" flight calls, while the four *Campephaga* cuckoo-shrikes are also rather silent but have whistling, churring or scratchy warbling songs. The Black Cuckoo-shrike sometimes gives a high-pitched, penetrating, insect-like trill when foraging or in flight.

Elsewhere, the trillers constituting the genus *Lalage* have a variety of calls, including trilling, chattering, chuckling, rattling or rasping notes. Most species have simple songs of repeated musical whistles or piping notes, but the somewhat aberrant Samoan Triller produces a thin, squeaky, ascending or descending trill that sounds as though it has been forced out with great effort. In the breeding season, the male White-winged Triller sings noisily from high perches and in frequent, loud and conspicuous song flights, giving a rapid series of "ditch" or "chur" calls followed

Campephagids often bind their nests together with spiders' webs, or even saliva, and sometimes they work the nest walls over underlying branches for added stability. The ***Varied Triller*** *builds just such a nest, barely large enough to accommodate a single egg. By reducing the structure and its contents to a bare minimum this species presumably succeeds, more often than not, in evading the prying eyes of predators. The eggs of campephagids are variable in colour, but most are off-white or bluish, with a dense pattern of darker blotches or speckles, sometimes gathered in a sort of wreath around the blunt end.*

[*Lalage leucomela leucomela*, near Gympie, south-east Queensland, Australia. Photo: Cyril Webster]

by a canary-like trill. Varied Trillers (*Lalage leucomela*) are noticeably vocal, uttering a loud, rolling, repeated call, and several individuals may call together to produce a widespread chorus. The two flycatcher-shrikes in the genus *Hemipus* and the two wood-shrikes in *Tephrodornis* also have trilling songs.

Minivets have simple, repeated, often trilling or twittering flight calls, or high-pitched, thin whistling or squeaky notes. Their whistling songs are simple, but are often highly variable within a species, and the distinction between songs and calls is sometimes not entirely clear. Flocks of minivets, with their bright colours and soft, musical contact calls, are much more obvious than are many other species in the family.

Duetting of some form or other is known to occur in at least seven species in the family. The song of the Red-shouldered Cuckoo-shrike of Africa is a medley, 5–10 seconds long, of squeaks, churrs and whistles, delivered simultaneously by the male and the female. The Moluccan Cuckoo-shrike has a harsh, staccato chatter, occasionally given by two individuals alternately, while Boyer's Cuckoo-shrike has an antiphonal duet of two or three hard notes followed by a sweet downslurred whistle, sounding like "(tuk)-tuk-tuk see-yu", the short notes given by the female and the whistle by the male. The calls of this species in the Wau area of eastern New Guinea include a different antiphonal duet, the first bird giving a "weeowee" and the second a lower-pitched "wurr". In mainland Papua New Guinea, the Barred Cuckoo-shrike has a plaintive, downslurred, whistling "whee", "whee-uuu" or "seeuu-seeuu-seeuu" which is often given as a duet in flight. Among the trillers, paired Black-browed Trillers (*Lalage atrovirens*) countersing with a sweet "tewhit tewheet wheetu".

It is in New Guinea that the two most dramatic examples of duetting by campephagids are found. The Golden Cuckoo-shrike has a "duet" in which groups of 2–4 individuals are involved. The leader gives a rapid series of about six identical notes, during the last 2–3 of which a second individual utters a whistled upslurred, downslurred or multiple-slurred call. This pattern is repeated continually as the birds chase each other in flight over a tree, or while perched. The group will then fly to another tree, duetting as they go, or with all group-members giving rapidly repeated notes similar to those made by the leader. This performance may be repeated for a long time as the birds move through the forest. A variety of other calls is also given, commonly in a duet. A basic call of the male is a rapid, bubbling, repeated "chirrapa", often with downslurred and upslurred notes added, and the female may make chipping or chuckling notes immediately before the male's call. The second example is that of the Black-bellied Cuckoo-shrike, which has a conspicuous, loud, precisely synchronized antiphonal duet. The male emits an upslurred whistle followed by a downslurred whistle, repeating this call several times; immediately after the beginning of each call, the female utters three or four harsh "kek" notes, completed before the end of the male's slur. The duet is usually carried out by a group of 2–4 individuals, and always while perched. The group flies from tree to tree, making "kek" calls in flight, and duetting each time the birds land. A group may use the same duetting trees and follow a prescribed route each day; one group followed a circular route of about 30 m in radius, returning to the same tree after half an hour.

The behaviour of the Grey-headed Cuckoo-shrike makes an interesting comparison with that of the Black-bellied Cuckoo-shrike. Both occur in the same forests of New Guinea, but are separated by altitude, the Grey-headed occurring at lower elevations. The display and song of the Grey-headed Cuckoo-shrike are very similar to those of the Black-bellied, except that there is no duetting. The perched male makes slurring notes, at the end of which several birds join in with rapid "chuk" calls, which they continue as they fly to the next tree. Bearing in mind the existence of other pairs of similar species separated by altitude in New Guinea, it has been suggested that such pairs originate when one population of a polytypic species, or one of a superspecies group, reinvades the range of a related population that has developed a different elevational preference during geographical isolation. The altitudinally separated members of such species pairs are often similar morphologically but have very different songs, suggesting that voice plays an important role in the isolating mechanisms. Thus, in addition to plumage differences, the synchronized duet of the Black-bellied Cuckoo-shrike, which could readily have evolved from a song resembling that of the Grey-headed Cuckoo-shrike, may function as an isolating mechanism between the two species.

A number of species exhibit marked geographical variation in the pattern and quality of vocalizations. One example among island species is the North Melanesian Cuckoo-shrike: on

Bougainville the call is a squeaky "mee-ahh-ahh", whereas on Guadalcanal it is a harsh, creaking "squeei". In Africa, the song of the Blue Cuckoo-shrike in Gabon is a powerful, downslurred "peeeoo" prefaced by a short "chup", while in Ivory Coast it is more nasal, a mixture of upslurred and downslurred notes. Similar vocal variation is demonstrated by the widespread Slender-billed Cicadabird, which occurs as 30 subspecies ranging from Micronesia, Sulawesi and the Lesser Sundas southwards to Australia and the Solomons. The nominate race, in Australia, has a cicada-like buzzing call, whereas *admiralitatis*, in the Admiralty Islands, gives a repeated, downslurred "seeu" and *monacha*, in the Palau Islands, a quiet, upslurred whistle. As a further example, the song of the Bar-winged Flycatcher-shrike in the Himalayas and South-east Asia includes a short, clear trill, that of the nominate race in the Western Ghats of India incorporates a hard trill, and that of the subspecies *leggei* in Sri Lanka includes a dry, thin, high-pitched trill.

Regional differences in voice are, in some cases, accompanied by significant morphological differences, and this has led to proposals for taxonomic splits. For example, the Scarlet Minivet (*Pericrocotus flammeus*), in most of its large range, utters loud, piercing, repeated whistles as flock contact calls, but the Himalayan subspecies *speciosus*, which is sometimes considered a separate species on the basis of its plumage colour, has a twangy, relatively low-pitched, single upslurred note. Similarly, the Bar-bellied Cuckoo-shrike (*Coracina striata*) has a loud, harsh "klee kleep" flight call in the Philippines, but in the Malay Peninsula and the Greater Sundas the subspecies *sumatrensis* has a clear whinnying "kliu-kliu-kliu" and a sharp "see-up", while the distinctive Andaman Islands race *dobsoni* emits a repeated, ear-splitting, shrieking call. The last-mentioned taxon is sometimes considered to represent a full species.

The calls of young campephagids are very poorly known. Young Black-faced Cuckoo-shrikes produce a begging "cher-reer" call in the nest and a buzzing begging call after leaving it. White-winged Triller chicks utter a peevish husky squeak.

Food and Feeding

Within the family as a whole, the diet consists predominantly of insects and other arthropods, and many campephagids take caterpillars, including hairy ones. The larger species consume relatively large prey, and even, occasionally, small vertebrates. Nevertheless, many species also eat fruit, especially wild figs (*Ficus*), and some are mainly frugivorous, taking insects only infrequently. Several also eat seeds, buds and other vegetable matter.

In keeping with our generally very limited level of knowledge of the family, the diet and food preferences of many of its members are very incompletely documented. Indeed, there is no available information on the food taken by 21 of the 84 species, including 15 of the 50 *Coracina* species. In part, this may be explained by the unobtrusive nature of many of these species, and their preference for foraging in the canopy, which can often make field observation difficult. Not unexpectedly, the most detailed information on food and feeding available is for the campephagids that occur in Africa and Australia.

The majority of cuckoo-shrikes in the genus *Coracina* eat arthropods, this being the principal food type recorded for 28 of the 35 species for which information is available. The four African species, the White-breasted, Grey, Blue and Grauer's Cuckoo-shrikes, are known to feed predominantly on caterpillars, while the Slender-billed Cicadabird of Wallacea, Micronesia and the Australian region is commonly known as the "Caterpillar-catcher" or "Caterpillar-eater", and the Bar-bellied Cuckoo-shrike appears partial to large, hairy caterpillars. The members of this genus often prey on large insects, including mantids (Mantodea), grasshoppers (Orthoptera), dragonflies (Odonata), large beetles (Coleoptera) and bugs (Hemiptera), cockroaches (Blattodea) and stick-insects (Phasmatidae). Other insects preyed upon include ants and wasps (Hymenoptera), termite alates (Isoptera) and flies (Diptera). Spiders (Arachnida), earthworms (Annelida) and snails (Gastropoda) make up the remainder of the invertebrate part of the diet. Large *Coracina* species, such as the Slaty Cuckoo-shrike of the Sulawesi region, the Black-faced Cuckoo-shrike of Australia and New Guinea, and the Hooded Cuckoo-shrike of New Guinea, are known to take small invertebrates such as lizards and, possibly, frogs, while the Mauritius Cuckoo-shrike preys on geckos of the genus *Phelsuma*.

At least 20 *Coracina* species eat fruit. This consists mainly of figs, but also comprises berries of such plants as *Lantana*, *Olea*, *Erxocarpus*, *Lycium*, *Terminalia*, *Calamus*, *Alphitonia* and mistletoe (Loranthaceae). Seeds, including those of the genera *Acacia*, *Cassia* and *Enchylaena*, are also recorded. The Barred,

In some genera, especially Campephaga *and* Pericrocotus, *nests are built by the female. Although she receives no direct assistance, she is often closely accompanied by the male, who seems to follow her permanently during the fertile period, presumably to guard against the loss of paternity to extra-pair males. Once the last egg has been laid, females begin to incubate, and males are free to make a more active contribution. They watch for predators in the vicinity of the nest, and occasionally bring food items to the female, as shown by this* ***Black Cuckoo-shrike****.*

[*Campephaga flava*, Nylstroom, Limpopo, South Africa.
Photo: R.P.B. Erasmus/ Photo Access]

*The best-documented instance of co-operative breeding in the family involves the **Ground Cuckoo-shrike**, a species that permanently lives in groups. These tend to contain a dominant pair and their subordinate helpers, apparently always the young from the previous season, if these have failed to encounter alternative breeding opportunities. It is not known whether helpers assist with incubation, but they do feed, brood and shade the nestlings, as well as chase conspecifics from the territory. On the rare occasions that two adult females have been present in a group, these either laid eggs in the same nest or built nests side-by-side.*

[*Pteropodocys maxima*, Australia. Photo: E. McNamara/ Ardea]

Boyer's, Grey-headed and Black-bellied Cuckoo-shrikes are largely frugivorous, with a diet made up mainly of wild figs. Otherwise, the Slender-billed Cicadabird and the White-bellied Cuckoo-shrike occasionally take nectar, and a few species sometimes eat plant material, such as leaves.

Insects are the principal food also of the African cuckoo-shrikes of the genera *Campephaga* and *Lobotos*, with lepidopteran larvae forming a large part of the diet of all six species. The food of the trillers is relatively poorly documented, and no data are available for five of the ten species. This genus appears to be largely insectivorous, although some species also take some fruit, mostly in the form of small berries, and some seeds, but the Black-browed Triller may be almost entirely frugivorous, as is the Varied Triller, at least in Australia. The White-winged Triller of Australia and New Guinea, although often known as a "caterpillar-eater", has a very diverse insect diet, which includes bees (Apidae) and ichneumons (Ichneumonidae), among others. It is known also to take fruit, seeds and nectar.

Similarly, the minivets are predominantly insectivorous, feeding chiefly on smaller prey than those taken by members of the other genera in the family. Vegetable matter apparently does not form part of the diet of most minivets, and the visits made by Fiery (*Pericrocotus igneus*) and Scarlet Minivets to fruiting fig trees are reportedly for the purpose of capturing insects attracted to the ripe fruit, and not to eat the fruit itself. The Long-tailed Minivet, however, supplements its diet with acacia buds and some fruit, while the Short-billed Minivet also eats some buds.

Not surprisingly, the flycatcher-shrikes and the wood-shrikes feed for the most part on insects. Finally, in the two monotypic genera, the Ground Cuckoo-shrike eats mainly insects, but takes prey up to the size of a House Sparrow (*Passer domesticus*), and the Golden Cuckoo-shrike, in contrast, feeds primarily on fruit.

From the little information available, it appears that the diets of young campephagids are similar to those of the adults. Thus, insectivorous species such as the Ground Cuckoo-shrike, the Slender-billed Cicadabird and the Black-faced Cuckoo-shrike feed their young on arthropods, consisting mainly of insects, while the frugivorous Barred Cuckoo-shrike provisions its nestlings mainly with fruit, especially figs, supplemented with some insects. Although adult Black Cuckoo-shrikes eat mostly caterpillars, they present their young with other insects, especially katydids (Tettigoniidae). A study of the Mauritius Cuckoo-shrike revealed that the diets of adults and nestlings differ only in the fact that small nestlings less than one week old, because they cannot cope with sizeable prey such as geckos and stick-insects, are not given the largest prey items.

Most of the Campephagidae are arboreal foragers, feeding mainly at levels from the middle to the canopy of trees in forest and woodland, and also in the crowns of isolated trees. The principal exception to this general rule is the Ground Cuckoo-shrike of Australia. This species, the largest in the family, lives in open country and forages mainly on the ground, walking and running to catch its prey, leaping into the air to catch insects, and sometimes sally-hovering above the ground, or above ground vegetation, before settling again. Other members of the family, principally those which occur in more open habitats, including forest edge, secondary growth, plantations, scrub, wooded farmland and gardens, sometimes forage on the ground. Examples in the genus *Coracina* are the Large, White-rumped and Black-faced Cuckoo-shrikes, the last of which often sally-pounces to the ground, and both the White-bellied and the Black-faced Cuckoo-shrikes have even been seen to take food scraps on the ground in school playgrounds. Similarly, the two wood-shrike species and the White-shouldered, White-winged and Polynesian Trillers capture prey on the ground in open habitats, while the White-bellied Minivet, which occurs in dry scrub, grassland, savanna, cultivation and even semi-desert, seeks food in low bushes, in grass and on the ground.

In open forests and woodlands in Australia, the White-bellied Cuckoo-shrike has been found to forage in lower strata during the wet season than those levels exploited in the dry season. The male Mauritius Cuckoo-shrike apparently tends to forage higher in trees than does the female, and it has been suggested that this could be associated with the male's display: males of this species usually sing from near the treetops, whereas females do not sing at all.

Species that forage in trees often move quite slowly and methodically. They glean arthropod prey while hopping or walking along tree trunks and branches; they diligently search foliage, including the undersides of leaves, and creepers and vines; and they hop or fly from branch to branch or from tree to tree. Several other prey-capture methods are also used. These include hawking

*In the **Black-faced Cuckoo-shrike** both adults share the task of building a nest on a horizontal fork, usually 8–20 m above the ground, but sometimes lower. In this the female lays two or three eggs, which are incubated by both sexes until they hatch around three weeks later. The nestlings are provided for, again by both sexes, until they fledge in a further 22–26 days, making the nesting cycle fairly long, despite which three broods are sometimes raised in a single season. Australian populations migrate north after breeding, some reaching New Guinea and Wallacea, a journey necessitating strong wings and long primaries.*

[*Coracina novaehollandiae melanops*, Woodanilling, Australia. Photo: Stanley Breeden/ DRK]

or sallying from a perch, sometimes an exposed one, sally-pouncing or striking, flutter-chasing, flush-pursuit, leap-snatching, hover-gleaning, and hovering over bushes or grass before dropping down on to prey items. The Reunion Cuckoo-shrike also probes bark and lichens, as does the Large Wood-shrike, which also takes insects from water surfaces. Frugivorous species, likewise, often move slowly and deliberately through trees while searching for food, although some, such as the Black-bellied and Grey-headed Cuckoo-shrikes, are active and noisy when feeding.

Large prey items are normally swallowed head first, and the largest are often struck repeatedly against a branch before being eaten. Hairy caterpillars are rubbed against a branch before being consumed. The Bar-bellied Cuckoo-shrike, when dealing with large figs, holds the fruit under one foot while picking it apart in order to eat it.

The only information available on foraging and feeding rates is for two species in Australia. During an 80-minute observation period, a male Slender-billed Cicadabird found and ate five insects, each about 30 mm long, which it obtained by gleaning along branches and by sally-hovering. The Black-faced Cuckoo-shrike is also reported as taking long periods, of 10–15 minutes, to obtain food items by gleaning and sally-striking.

All campephagids can occur singly, in pairs or in small groups while foraging, and many are commonly recorded in groups, especially outside the breeding season, when minivets, in particular, often gather in quite large flocks. A good number of species, especially those of forest and woodland habitats, regularly join mixed-species foraging flocks, this behaviour occurring among frugivorous as well as insectivorous species (see General Habits). Such foraging flocks frequently include several campephagid species.

Breeding

Detailed studies of breeding have been made for very few species in the family. Indeed, fairly comprehensive information has being recorded for only twelve species, six from Australia, four from Africa and two globally threatened species of Indian Ocean islands, the Mauritius and Reunion Cuckoo-shrikes. The breeding of some species occurring in India is also fairly well documented. For as many as 39 of the family's 86 species, however, including eight of the twelve *Lalage* trillers and 27 of the 50 *Coracina* cuckoo-shrikes, there is no real information at all on breeding habits. In a very few cases, the months in which breeding occurs or the dates on which nestlings have been found are documented, but no other information is available, and in others only observations of juveniles, or of adults in breeding condition, give some indication of the breeding period.

All species for which relevant information is available are territorial during the breeding season, and some resident species are known, or believed, to be permanently territorial. Monogamy is the rule, and in the case of resident species the pair-bond appears to be strong throughout the year. The single recorded exception to a monogamous mating system is one instance of polygyny, recorded for the White-winged Triller in Australia. In this case, one male and two females occupied a territory; the females used separate nests and each fledged two young, and the male assisted at both nests.

Co-operative breeding has been recorded for several campephagids and may be more widespread in the family than is currently realized. The best-documented example is that of the Ground Cuckoo-shrike of Australia, which normally lives in groups, often containing both adults and young. Helpers appear to be young from the previous season that did not breed at the end of their first year but, instead, help their parents to build the nest and to feed, brood and shade the nestlings. It is not known if helpers assist with incubation, and they do not always assist with brooding, but they do also feed fledglings. Helpers may also chase conspecifics and other bird species away from the nest, or even out of the territory. Occasionally, Ground Cuckoo-shrikes build two nests close together; in one instance, two were placed within 1 m of each other on the same branch, and the nestlings in both were attended by five individuals. Two females occasionally share a single nest, both laying in it, and two nests containing six eggs were each attended by four adults. Co-operative breeding may sometimes occur with the Black-faced Cuckoo-shrike in Australia, as immatures have been observed to attend nests, and an immature was once seen to brood nestlings. In South-east Asia, a pair of Grey-chinned Minivets was assisted by two subadults, possibly its offspring, in tending the nestlings, and co-operative nest-building by the Scarlet Minivet was observed on one occa-

The nest of the ***White-winged Triller*** *is a small, neat saucer built by both sexes. It is made of tiny plant fragments such as dry grass, tendrils and strips of bark, bound with cobwebs and placed on a horizontal or slightly sloping fork of a relatively slender branch, usually 1–12 m above the ground. Both sexes incubate the clutch for around 14 days and feed the brood for a further 12 days, after which the young fledge. One of the most peculiar aspects of breeding behaviour in this species is the fact that it is semi-colonial. Up to seven nests have been counted in a single tree, or 15 in a small clump of trees. Interestingly, these nests are often sited close to those of other black-and-white birds, such as Magpie-larks* (Grallina cyanoleuca) *and Willie-wagtails* (Rhipidura leucophrys).

[*Lalage tricolor*, Manmanning, Western Australia. Photos: Graeme Chapman]

Nestling cuckoo-shrikes are downy and heavily speckled, the latter a feature which helps to camouflage them amongst lichen-encrusted branches, especially when the nest itself is decorated with lichen. In terms of placement and architecture, as well as nestling morphology, campephagid nests bear a striking resemblance to those of certain Neotropical canopy-dwelling cotingas (Cotingidae), no doubt because both families have converged on an optimal predator evasion tactic. If the ploy is successful this brood of ***White-breasted Cuckoo-shrike*** *will fledge around 25 days after hatching, finally reaching independence a full three months later.*

[*Coracina pectoralis*, Marondera, Zimbabwe. Photo: Cyril Laubscher]

sion, when a party of about ten individuals, including apparent immatures, brought material to the nest in turn.

Many campephagids for which information is available appear to breed during or just after the rains, or, in temperate regions, during the summer. Some species in high-rainfall regions, however, tend to avoid the wettest months and may even breed during the dry season. For several members of the family, breeding is recorded in most or all months of the year, and this includes those species inhabiting dry regions with often irregular rainfall, such as those that are widespread in Australia. Thus, the Ground Cuckoo-shrike, which often occurs in dry areas, breeds in all months, but mainly from August to December or January, and after rain in arid regions. Similarly, the Black-faced Cuckoo-shrike breeds in northern Australia from May to December, before and during the summer rains, and in southern Australia from August to January, mainly after the winter rains, but it may nest at any time of the year after good rains, especially in arid regions.

In Africa, the breeding season is normally centred on the rains. The Black Cuckoo-shrike nests mainly during the rains, the White-breasted Cuckoo-shrike mainly from the end of the dry season through the rains, and the Purple-throated Cuckoo-shrike during and at the end of the rains. In New Guinea, Stout-billed and Black-bellied Cuckoo-shrikes probably breed late in the dry season and early in the wet season, while the Fiery Minivet breeds in the December dry season on Palawan, in the Philippines, but in May, at the start of the rains, in Peninsular Malaysia.

Members of the family in the Indian Subcontinent breed primarily during the summer, from March to September, the period varying locally. The Large Cuckoo-shrike, however, is unusual in that, in western India, it apparently has two breeding periods, nesting in February–April and also in August–October.

Courtship chases and pre-copulatory displays have been described for a number of species. The male White-winged Triller, for example, pursues the female through the trees, singing constantly and with a buoyant, floating flight. Paired Black Cuckoo-shrikes often move about together in the breeding season, the male following the female closely and performing a fluttering, moth-like flight near her when excited. Some of the larger cuckoo-shrikes have a courtship display in which the male repeatedly lifts each wing alternately, without opening it, calling strongly while doing so. This same behaviour has been recorded for the Large Cuckoo-shrike in India, which also indulges in courtship chases while uttering its shrill, screaming calls. In New Guinea, the White-bellied Cuckoo-shrike performs a pre-copulatory display in which the male and female, facing each other on a perch, repeatedly raise and lower their wings. A different kind of display is demonstrated by the Slender-billed Cicadabird, in which the male jumps towards the crouching female, with his tail fanned and wings partly spread, and bows towards her with his neck extended. A similar bowing display is given by the Barred Cuckoo-shrike, while the male Varied Triller hops about and bows to the female with jerky movements, calling constantly, immediately before copulation.

Some minivets have impressive courtship-flights and displays, soaring up and then spiralling downwards on outstretched wings to perch on the top of a tree. A female Scarlet Minivet was seen to fly high into the air, pursued by the male, which seized her tail tip in his bill, whereupon both spiralled down, the male releasing the female before perching again; the procedure was then repeated. In another observation, a male Grey-chinned Minivet, holding a white flower in his bill, approached a female; he tilted his head from side to side, swinging the flower, and presented it by touching the female's bill before dropping it. Copulation followed immediately.

Although the majority of campephagids are solitary nesters, the White-winged Triller often nests colonially, with up to seven nests in one tree or 15 pairs in the same clump of trees. This species often nests close to other black-and-white birds, such as Magpie-larks (*Grallina cyanoleuca*) and Willie-wagtails (*Rhipidura leucophrys*). Colonial nesters each maintain a small individual territory, the size of which has not been described. Hardly any information is available on the size of breeding territories, but the Reunion Cuckoo-shrike holds territories of 6–8 ha, while the territory size of the Black-faced Cuckoo-shrike is at least 10 ha. The highest breeding density recorded for the Mauritius Cuckoo-shrike is 25 territories per square kilometre.

All members of the family nest in trees, and many build in tall forest trees high above the ground. Heights of 10–20 m are common, although some species, including the wood-shrikes, nest lower than this. The maximum recorded height, involving a nest of the Black-winged Flycatcher-shrike, is 40 m above the ground. The White-bellied Minivet, because of its occurrence in arid areas with scrub and low vegetation, utilizes small trees and shrubs, nesting only 1–2 m above the ground. All species usually place the nest on a horizontal fork or branch, or sometimes on a slop-

ing branch, and often near the end of the branch and not among foliage. The nest is difficult to see from below.

Both sexes may look for a suitable nest-site, searching either separately or together. Studies of the White-winged Triller have revealed that the finder of a suitable site settles there, and its mate approaches, hops closely around its partner, and takes its place when its mate moves off. Nest-building normally starts within 2–4 days at the selected site. A pair of Ground Cuckoo-shrikes can occupy the same area for many years, and nest in the same tree year after year. Some species may occasionally build inside old nests of other birds. The Ground Cuckoo-shrike, for example, occasionally builds in old nests of Magpie-larks, White-winged Choughs (*Corcorax melanorhamphos*) or Apostlebirds (*Struthidea cinerea*).

All campephagids build very small, inconspicuous, saucer-shaped or cup-shaped nests, sometimes only just big enough to contain the eggs. Materials used include fine twigs, roots, bark, grasses, casuarina needles, lichens, moss, vine tendrils, plant down, wool and horsehair. Most species bind the materials together and anchor the nest to the branch with spider webs, and some apparently use saliva to bind the materials of the sides and rim. Nests are usually lined with soft vegetation, including fine fibres, fine grass, rootlets, moss, hairs, leaves and feathers, but those of some of the large *Coracina* species are left unlined. Many species camouflage the nest by adding pieces of lichen, moss or bark to the outside. Sometimes, as is the case with, for example, the Varied Triller, the outer portion of the nest is worked over the branch on which it is placed. Minivets, the smallest members of the family, tend to build comparatively bulky nests.

In many species, both sexes share in the task of nest-building. In some cases, particularly with species in the genera *Campephaga* and *Pericrocotus*, the female usually builds, while the male accompanies her but does not undertake any of the work. Both sexes of the Barred Cuckoo-shrike collect material, but only one of the two may build, while the male of a pair of Black-winged Flycatcher-shrikes brought materials while the female shaped the nest. The work of nest-building can take time: the female White-breasted Cuckoo-shrike requires about six days and the female Black Cuckoo-shrike up to ten days to complete the nest.

Campephagid eggs are normally oval to elongated oval in shape, but sometimes more rounded, and are smooth and, often, glossy. The ground colour varies from white, as in some minivets and the wood-shrikes, through olive, pale green, pale blue-green or pale blue-grey, as in some *Coracina* species, flycatcher-shrikes and trillers, to olive-green, yellow-olive, darker green or blue-green, as in *Campephaga* and some *Coracina* species. The eggs of almost all species are spotted or blotched, and sometimes also streaked or squiggled, with brown, which varies from pale brown to deep red-brown, purple-brown or even blackish brown, and often have undermarkings of grey, lilac or violet. Those of some species have the markings concentrated in a zone or, more rarely, a ring at the blunt end.

The clutch is of 1–5 eggs, two or three being the commonest number. The minivets and the wood-shrikes lay the largest clutches, often consisting of three or four eggs, and the Ashy Minivet sometimes lays five eggs. In contrast, several species in the genera *Coracina* and *Lalage* regularly lay only a single egg. The laying interval has been recorded for very few species: for the Mauritius Cuckoo-shrike it is one day, for the White-winged Triller it is two days, occasionally shorter, and for the Black-faced Cuckoo-shrike it can be more than 24 hours. Some species are known to re-lay after the loss of eggs or young.

Incubation is undertaken solely by the females of some species, but the duty is shared by both sexes of others. The incubation period is often protracted, varying from 14 days in the White-winged Triller to 21–27 days in members of the genus *Coracina*. In many cases, the sitting female is fed by the male, which also defends the area near the nest. From the very little information available, it appears that incubation commences when the last egg is laid and that hatching is usually synchronous. The chicks are altricial and nidicolous. On hatching, they are blind and naked, but they develop whitish or greyish down within about four days. This down, together with the often dull-coloured skin, renders the young camouflaged on the small nest, placed, as it is, among greyish or grey-brown branches. The chicks of the Bar-winged Flycatcher-shrike, for example, have grey down, sit in rigid stillness with the beak pointing vertically upwards, and are almost invisible to intruders. The nestlings of the similarly camouflaged Large Wood-shrike behave in a similar manner.

Generally, both sexes feed and brood the young, and remove from the nest, or swallow, their faecal sacs. With a few species, however, only the female cares for the chicks, and sometimes

Not surprisingly, adult campephagids feed their nestlings large quantities of soft-bodied insects, a perfect diet for growth and development. In the ***Black-faced Cuckoo-shrike*** *the proportion of fruit and invertebrates in the diet of young birds is not thought to differ from that of adults. In other words, adult birds select the same types of prey for their brood as they do for themselves, although very young hatchlings must be fed relatively small items. It also seems likely that the frugivorous species in* Coracina *might switch to a more insect-based diet in the nestling phase, but this remains to be investigated.*

[*Coracina novaehollandiae*, near Gympie, south-east Queensland, Australia. Photo: Cyril Webster]

*The largest clutches known in the family are laid by the **Ashy Minivet**. This nest contains a brood of three chicks, but clutches of up to five eggs are not uncommon. This fact makes sense in the light of its breeding distribution, which extends into north China and Siberia as far as 52°N. As can be seen from this example, minivet nests are typical in design, but large in relation to body size. Most are built by the female alone, but in at least one group-living species the whole group was seen to collaborate in the construction phase. This suggests that some type of co-operative breeding occurs, but nothing else is known.*

[*Pericrocotus divaricatus divaricatus*, Ussuriland, Russian Far East. Photo: Yuri Shibnev]

only the female broods the young but both parents feed them. The adults also shade the nestlings from the sun and may cover them during rain. Fledging periods are documented for very few campephagids but, as with incubation periods, are generally long, lasting between 20 and 30 days, the longest recorded period being for the White-breasted Cuckoo-shrike of Africa. At the opposite extreme, the White-winged Triller, as well as having the shortest incubation period, of 14 days, has the shortest fledging period, the duration of which is just 12–14 days. Observations made on White-bellied Cuckoo-shrikes have revealed that the adults of this species, in order to encourage the youngsters to fly, push them out of the nest; in one instance, a nest was pulled apart before all the brood had fledged.

Among all species for which information is available, the fledged young remain with the parents for some time after leaving the nest. They may be fed by them for up to two months, and in the case of the White-breasted Cuckoo-shrike for as long as three months. The juveniles often remain with their parents until the next breeding season, at which time they may be driven out of the territory. This is typical with, for example, the Black-faced Cuckoo-shrike. With species that are double-brooded, such as the White-winged Triller in Australia, the male drives away the offspring as the pair begins the second nesting attempt.

Most campephagids rear only one brood in a season. The few for which two broods have been recorded include, in addition to the aforementioned, the Reunion Cuckoo-shrike, the Black-winged Cuckoo-shrike in China, the Pied Triller in Singapore and the Scarlet Minivet in India and Sri Lanka. A further species, the Black-faced Cuckoo-shrike, is capable of raising up to three broods per season.

The age at which campephagids first breed is uncertain, but it is assumed to be one year. Black-faced Cuckoo-shrikes are reported as breeding in immature plumage, when they are presumably less than one year old.

Very few data exist on the breeding success of the members of this family. Hatching success reportedly varies between 49% and 73%, and is highest for the Ground Cuckoo-shrike and the Black-faced Cuckoo-shrike. Fledging success of 27% is reported for the White-winged Triller and of 42% for the White-breasted Cuckoo-shrike. In other studies, the number of young successfully reared per breeding attempt was 0·75 in the case of White-bellied Cuckoo-shrikes and 0·93 in the case of Reunion Cuckoo-shrikes.

Brood parasitism is recorded for campephagids in Australia, where several cuckoo species sometimes lay their eggs in the nests of this family. The White-winged Triller is parasitized by the Pallid Cuckoo (*Cuculus pallidus*), the Brush Cuckoo (*Cacomantis variolosus*), the Fan-tailed Cuckoo (*Cacomantis flabelliformis*) and the Shining Bronze-cuckoo (*Chrysococcyx lucidus*); the Slender-billed Cicadabird is parasitized by the Pallid Cuckoo; and the Black-faced Cuckoo-shrike falls victim to the Common Koel (*Eudynamys scolopacea*) and the Pallid Cuckoo. There is no evidence that any African cuckoo-shrike suffers brood parasitism.

Movements

In view of the largely tropical and subtropical distribution of the family, and the relatively small proportion of species living in regions and habitats where environmental conditions vary markedly by season, it is not surprising that movements are recorded for only a minority of the 86 species. Nevertheless, the Campephagidae do provide examples of all the major types of movement strategy, including regular seasonal latitudinal migration, seasonal altitudinal migration, nomadic and irregular movements, and seasonal dispersive movements. Although many species are poorly known, sufficient information is available to give a good indication of movement patterns in the family.

Of the 60 species for which no movements are recorded, 53 occur exclusively or principally in forest habitats, which are relatively stable, and a further six inhabit both forest and woodland. The only sedentary species that occupies a wide range of generalized habitats, in addition to forest and woodland, is the White-throated Triller. This is one of 52 sedentary species, all largely forest-dwelling, that occur on islands in the Indian Ocean and the western Pacific, this total including those occupying large islands such as New Guinea and Madagascar. In fact, there is no evidence that significant movements are made by any of the campephagids on islands in these regions. Furthermore, of the 26 species which do undertake movements, four, the White-bel-

In most campephagids females tend to shelter the chicks for the first few days after hatching, but this ***Black Cuckoo-shrike*** *seems to be taking her brooding duties too seriously. In this species, both sexes feed the young for 20–23 days, apparently bringing them relatively few caterpillars in comparison with the adult diet, and rather more orthopterans, though this is based on scant evidence.*

[*Campephaga flava*, Stone Hills, Matobo, Zimbabwe. Photo: Richard Peek]

lied Cuckoo-shrike, the Slender-billed Cicadabird, the Barred Cuckoo-shrike and the Varied Triller, have island populations in this region. Their global distributions extend from Wallacea to New Guinea, Melanesia and Australia and, in the case of the Slender-billed Cicadabird, to Micronesia, but, for each of the four, it is only the populations breeding in mainland Australia that exhibit movements.

Significant movements are evident only in continental populations of campephagids, and the longest and most marked are made by those species, especially the minivets, that breed in the more temperate areas of southern and eastern Asia, such as the Himalayas, China and Russia. These movements fall into two principal categories: latitudinal and altitudinal. Seven minivet species undertake regular movements, and three of these make long migrations. The nominate race of the Ashy Minivet breeds in south-eastern Siberia, north-eastern and eastern China, Japan and Korea, and migrates south to South-east Asia and Peninsular Malaysia, the Philippines and the Greater Sundas, while Swinhoe's Minivet breeds in China and spends the winter months in South-east Asia and the Malay Peninsula. The Rosy Minivet is a resident and partial migrant, breeding from northern Pakistan eastwards through Nepal to southern China, and wintering south to central India and continental South-east Asia. The four other migratory minivet species, the Grey-chinned, Scarlet, Short-billed and Long-tailed Minivets, have resident populations and also migratory Himalayan populations, the latter descending to lower elevations after breeding.

There are five other migratory mainland Asian species, but only two of them are long-distance migrants. The Black-winged Cuckoo-shrike makes latitudinal and altitudinal movements, with Himalayan populations wintering in northern India and Chinese populations moving as far south as Indochina and the Malay Peninsula. Northern populations of the Black-headed Cuckoo-shrike, breeding in Nepal and northern India, winter at lower elevations and also farther south, some reaching Myanmar. The other three species, the Large Cuckoo-shrike, the Bar-winged Flycatcher-shrike and the Large Wood-shrike, make seasonal movements to lower elevations in the Himalayan parts of their ranges. The Large Cuckoo-shrike, which occupies a wide range of habitats, is also locally nomadic.

The most detailed information on movements comes from Africa and Australia. In Africa, four species exhibit regular migration. The widespread Black Cuckoo-shrike, of predominantly woodland habitats, has complex and incompletely understood movements, being variously resident, nomadic and migratory. In southern Africa, it breeds in plateau country during the rains and then moves down to lower altitudes; such movements are apparently influenced by rainfall, fewer birds moving away from the breeding areas in wet years. Many individuals in other regions fly north to the equator after breeding, and this species is mainly a non-breeding visitor to East African countries. In addition, it occurs in southern coastal regions throughout the year. Some West African populations of the forest-dwelling Red-shouldered Cuckoo-shrike migrate northwards to breed during the rains, and return to the edge of the forest belt in lower latitudes in the dry season, but elsewhere the species is largely sedentary or nomadic. The White-breasted Cuckoo-shrike is for the most part a resident inhabitant of woodland and savanna, but in some areas it makes seasonal shifts, either to lower elevations or to drier areas. Similarly, the Grey Cuckoo-shrike is largely resident in forest, but some of its populations make altitudinal movements.

In Australia, where in many regions rainfall is irregular or shows great seasonal variation, members of the family exhibit several types of movement. The Ground Cuckoo-shrike is considered resident in some areas, but in others it is regarded as nomadic, with movements that sometimes show no definite general pattern, apparently not being influenced by local rainfall or temperature. In some areas, however, its presence appears to be related to drought, bush fires and the availability of food, and some seasonal occurrences are noted, individuals usually being classed as irregular and uncommon non-breeding visitors. Tasmanian populations of the Black-faced Cuckoo-shrike spend the austral winter in mainland Australia, while those breeding in eastern Australia migrate to the northern parts of the country and to New Guinea, and in smaller numbers westwards to parts of Wallacea. The White-bellied Cuckoo-shrike, on the other hand, is mainly resident, but it apparently shows some seasonal movements and is locally nomadic during the dry winter season, when it occurs uncommonly on islands in the Torres Strait. Finally, the Slender-billed Cicadabird and the White-winged Triller fly south to breed,

*The nest of the **Varied Triller** is designed to hold a single egg, but is no match for a growing nestling. Only mid-way through the nestling period this young bird has burst through the rim of the tiny nest, and will soon have to cling onto the branch to prevent itself from tumbling to the ground. The inadequacy of the nest structure as a housing for young birds is presumably even more pronounced in the case of brood parasitism. Trillers are known to be parasitized by Shining Bronze-cuckoos* (Chrysococcyx lucidus), *which are hardly larger than the host, as well as by Brush* (Cacomantis variolosus) *and Fan-tailed Cuckoos* (Cacomantis flabelliformis), *which are slightly larger. Largest of all is the Pallid Cuckoo* (Cuculus pallidus), *a species that must almost certainly flatten triller nests within a day or two of hatching.*

[*Lalage leucomela leucomela*, near Gympie, south-east Queensland, Australia. Photo: Cyril Webster]

*The nestlings of this **Pied Triller** are almost ready to fledge, but they persist in clinging to the vicinity of the nest-site. They have long since outgrown the nest itself, which has collapsed, and hangs in tatters from its original location. In these last days before fledging the provisioning rate is at its peak, both in terms of rate of visits and the size of items brought by the parents. This species is the only member of* Lalage *to have reached continental Asia, this being an Australasian genus in terms of evolutionary history.*

[*Lalage nigra striga*, Kranki Dam, Singapore. Photo: Jimmy Chew]

after which they head northwards, some reaching New Guinea. The triller also appears irregularly in many of the more arid districts of Australia, depending on the rains, and can be common in desert areas in wet seasons.

The only information on dispersal derives from studies of the Reunion Cuckoo-shrike. Seasonal occurrences of this species in atypical heath habitat are attributed to post-breeding dispersal.

Few data are available on the migratory behaviour of these campephagids. Some migrate at night, as is evidenced by kills recorded at lighthouses in Australia (see Status and Conservation) and by records of migrating Black Cuckoo-shrikes being attracted to lights at night in Kenya, in East Africa. In south-east Russia, however, the Ashy Minivet is known to migrate during the day, when passage is readily detectable because the flocks call in flight. This species is said to make post-breeding movements in flocks, but spring movements in small parties or singly. The Black-faced Cuckoo-shrike collects in large flocks in Australia before it moves north, apparently in a broad front across the Coral Sea, to New Guinea. Migration has been observed throughout the day, and the birds readily cross large expanses of water, flying about 10–12 m above the surface, either with or against the wind. Still in Australia, it has been noted that the sexes of the Slender-billed Cicadabird may migrate separately, the males apparently leaving before the females, juveniles or immatures, and also returning first in the spring. Likewise, the White-winged Triller migrates in flocks, containing up to 60 or so individuals, and the sexes appear to travel separately, the males arriving and departing first. This species, too, can cross large stretches of water, and vagrants have occurred in Tasmania and even New Zealand, although such long-distance movements are, at least sometimes, ship-assisted.

Relationship with Man

Although some members of the family, especially the minivets, are brightly coloured, and despite the fact that these and many other species are quite vocal, the family apparently has no cultural significance in human affairs. Because they are mainly forest-dwellers, usually foraging at treetop level, and are unobtrusive in nature, most campephagids do not come into frequent contact with humans and are easily overlooked.

The majority of the species do not occur in large flocks, and there is no evidence that any one of them has any significance in an agricultural context. The frugivorous species feed mainly on figs and do not forage in numbers large enough to cause damage to commercial crops. Moreover, the diet of the insectivores could be considered to render these species, on balance, beneficial in areas where they forage in plantations and agricultural land.

As may perhaps be expected, the cuckoo-shrikes, minivets and allies are apparently not hunted or trapped to any major extent. In the nineteenth century, it was recorded that, in India, the flesh of the Large Cuckoo-shrike was "eaten and esteemed by some of the natives". This seems, however, to be something of an exception for, so far as is known, campephagids do not feature among the birds prized for the quality of their flesh.

Probably the most important association between this family and humans relates to the interest that they arouse among ornithologists. Minivets, for example, with their brightly coloured plumages, provide a regular delight for birdwatchers visiting the southern and south-eastern parts of Asia.

Status and Conservation

Thirteen species in the family are of conservation concern, but only four of these are currently considered to be globally threatened.

The Reunion Cuckoo-shrike is the only campephagid classified as Endangered, by virtue of its very restricted island distribution and its extremely small population. It is confined to the island of Reunion, in the western Indian Ocean, where the number of mature individuals was estimated at 240 in 1991, at which time it was suggested that the population had been stable since 1974. In 2000, this species was found to occupy a very small range of 16 km², made up of two areas of increasingly degraded forest habitat, in the north-west of the island, and its breeding population was estimated at 60–160 pairs. Its current habitat comprises closed mixed evergreen subtropical forest, often with areas of the heath *Philippia montana* and tamarin (*Acacia heterophylla*), at elevations of up to 1850 m; records in the heath are attributed to post-breeding dispersal.

This species seems unable to colonize new areas, and it is suggested that poor breeding success or poor survival, coupled

*The **New Caledonian Cuckoo-shrike** is endemic to the South Pacific island of New Caledonia, a fact that ensures its permanent treatment as a restricted-range species. It remains widespread in humid forest patches, several of which receive some form of protection, and is therefore not thought to face any immediate risk of extinction. Of all the New Caledonian endemic birds that are not classified as threatened, however, it is perhaps the most uncommon. Its status and distribution should be monitored, and the protected-area network serving New Caledonia's unique avifauna should be expanded wherever possible.*

[*Coracina analis*, Rivière Bleue Reserve, New Caledonia. Photo: Joe Tobias]

with population fragmentation, may prevent it from spreading. Further habitat loss, as a result of degradation by the invasion of exotic vegetation, for example, could therefore have devastating consequences. Other threats to its habitat include tree-felling, agriculture, development for tourism and recreation, and damage by introduced deer. Poaching and hunting, and the predation of nests by cats and rats (*Rattus*), may be major problems. The very small population is at risk also from catastrophic events such as cyclones and extensive fires, which occur regularly on Reunion.

The Reunion Cuckoo-shrike's narrow habitat tolerance, its inability to colonize other areas of similar forest, and its rather low population density are unusual characteristics in an island endemic. Such bird species typically attain a high density and occupy a relatively broad habitat niche, as apparently do all other native forest birds on Reunion. Heavy deforestation since the seventeenth century has led to contraction and fragmentation of the cuckoo-shrike's formerly widespread range on the island, and the surviving population may be forced to subsist in suboptimal habitat in the last remaining extensive forest patches at higher altitudes. Its former distribution was centred on lower elevations, where natural forest has now almost disappeared.

In 1999, the 38-km² Roche Ecrite Reserve, which encompasses most of the species' range, was being established, and plans for habitat management were being formulated. These include a logging ban, control of exotic plants, the establishment of firebreaks, better control of hunting, the curbing of tourism, and action to reduce deer numbers. An experimental translocation of Reunion Cuckoo-shrikes to a lowland site has also been suggested, with the aim of creating a second population as an insurance against the stochastic extinction risk faced by the species' current small, isolated population.

Of the three Vulnerable species, the Mauritius Cuckoo-shrike is restricted to southern Mauritius, where it has a very small range of about 117 km². Its population in 1993 amounted to no more than about 260 pairs, but it has responded well to the recent rehabilitation of native ecosystems. Its population was estimated at 300–350 pairs in 2000 and is still increasing, and the species has colonized two lowland areas contiguous with its previous range. It is apparently strictly territorial throughout the year, and its distribution in forest seems to be linked to food availability. Habitat loss and degradation, through invasion by exotics and poor regeneration of native plants, remain a long-term threat. There is circumstantial evidence that the use of organochloride pesticides in the 1950s and 1960s also caused a population decline, from which the species seems to have largely recovered. Introduced predators and natural cyclones take a heavy toll on nests, while the introduced Common Myna (*Acridotheres tristis*) may be a food competitor. The Black River Gorges National Park covers most of this cuckoo-shrike's range, and it has benefited from the rehabilitation of habitat in Conservation Management Areas. It is intended to translocate pairs to new areas on Mauritius, and also, eventually, to adjacent islets.

In the Philippines, the White-winged Cuckoo-shrike (*Coracina ostenta*) is also listed as Vulnerable. Like many other

*The **Cerulean Cuckoo-shrike** is another restricted-range campephagid that is not thought to be globally threatened. It is restricted to the Indonesian island of Sulawesi, where it remains generally common and conspicuous in humid forests of the foothill and montane zone. Effective long-term management needs to be ensured for all protected areas embracing this habitat, perhaps especially at Lore Lindu, where a healthy population of this species survives, alongside most of Sulawesi's unique montane fauna.*

[*Coracina temminckii rileyi*, Lore Lindu National Park, Sulawesi. Photo: Bernard Van Elegem]

*One of several trillers restricted to small oceanic islands, the **Polynesian Triller** occurs in a variety of South Pacific archipelagos, including Vanuatu, Fiji, Tonga and Samoa. The total land area of these island groups is very small, however, resulting in its classification as a restricted-range species. Fortunately, it has adapted well to degraded habitats and man-modified environments, such as scrubland, gardens and roadsides, and most of its subspecies are therefore thought to be secure.*

[*Lalage maculosa maculosa*, Samoa. Photo: Roland Seitre]

avian species in the region, it is undergoing a rapid population decline following large-scale destruction of its forest habitat at low to middle altitudes. Its range is small, covering 23,000 km², fragmented and shrinking. It is now restricted to a few localities on the islands of Negros and Panay, both of which have suffered massive forest destruction, and it is almost certainly extinct on Guimaras, the only other island from which it has been recorded, as a result of near-total deforestation. Large trees appear to be an essential requirement of this campephagid, as a consequence of which it suffers heavily from logging; although some records suggest that it can survive in secondary forest, albeit at relatively low densities, small patches of less than 50 ha may be unsuitable. Habitat degradation, particularly the selective logging of large trees, poses a serious threat to this species. It is rarely recorded above 1100 m, and much of the surviving forest within its range lies above this altitudinal limit. Significant populations are unlikely to survive in montane forest, and it occurs at relatively low densities in secondary forest.

The third Vulnerable species, the Western Wattled Cuckoo-shrike of West Africa, is confined to the canopy of primary or tall lowland rainforest and open swamp-forest. It seems able to tolerate some habitat modification, as it is also recorded in logged, disturbed and managed forest, and in Ivory Coast it has been found in *Terminalia ivorensis* plantations; it can breed in mature logged forest. Despite these adaptations, this campephagid must be seriously threatened by massive forest destruction throughout its fragmented range of 300,000 km². It is locally rare to uncommon, and its population may be declining rapidly. Its sole congener, the Eastern Wattled Cuckoo-shrike (*Lobotos oriolinus*) of the more central parts of Africa, is listed as Data-deficient. This poorly known species is uncommon to very rare throughout its potentially wide range, but the reasons for its rarity are unclear. It is not likely to be immediately threatened by habitat loss, as it appears to prefer secondary forest.

Nine members of the family are currently placed in the conservation category of Near-threatened. Seven are confined to islands, and six of these, including one minivet species, occur in Indonesia or the Philippines, where forest destruction has been severe. In Indonesia, the Buru Cuckoo-shrike is restricted to the island of that name. Although apparently uncommon and locally distributed, it is probably little affected by recent habitat changes because it occurs in disturbed areas, and its preferred habitat appears to be higher-altitude forest with an open understorey. The Pied Cuckoo-shrike (*Coracina bicolor*) is confined to islands in Indonesia, where its range is fragmented. Forest destruction within its altitudinal limits has been extensive, and its populations must have declined, but it does, nevertheless, occur in forest with clearings. The Kai Cicadabird (*Coracina dispar*), restricted to the Banda Sea Islands Endemic Bird Area, inhabits forest and secondary woodlands. It appears to be uncommon but, as it is easily overlooked, it is possible that it is locally more numerous. The condition of some of the islands on which this cicadabird occurs is unknown, and an assessment of its true status is therefore very difficult.

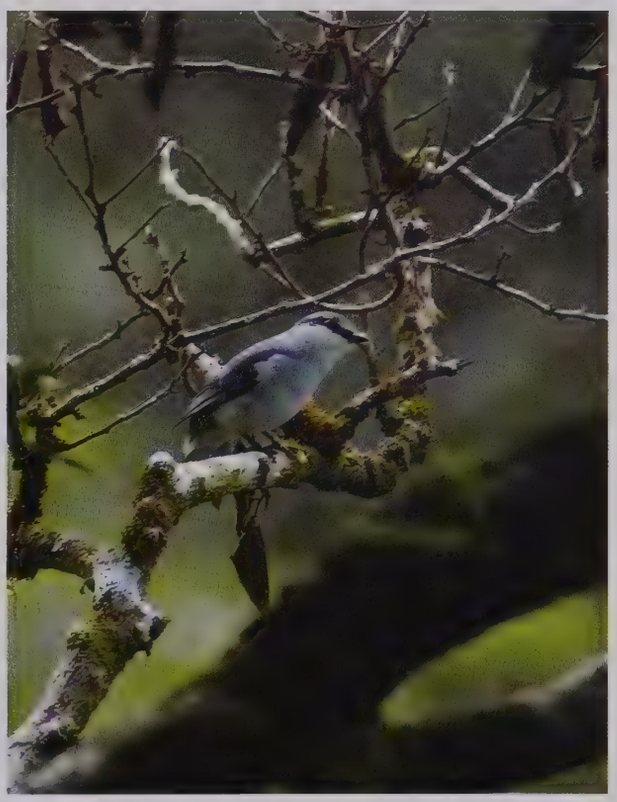
In the Philippines, the Black-bibbed Cicadabird (*Coracina mindanensis*) is found on a dozen islands, and three of its five races are considered rare. Most records of this species have been made at elevations well below 1000 m. This apparent preference for lower-altitude forest suggests that it must have suffered population declines with the destruction of lowland forest in the region. McGregor's Cuckoo-shrike is found only on the Philippine island of Mindanao, where it is apparently common in montane forest at 1100–1900 m. Although forest above 1300 m is now seriously threatened by clearance at one locality, habitat at these higher altitudes is generally fairly secure.

The only Near-threatened minivet, the Fiery Minivet, is restricted to the Sundaic lowlands in the southern Malay Peninsula, Indonesia and the south-west Philippines. Forest destruction in these lowlands has been very extensive, but this minivet occurs also on submontane slopes, where forest destruction has been less severe, and in secondary growth, and it is thought not to be immediately threatened. Farther east, the Solomon Cuckoo-shrike (*Coracina holopolia*) is generally scarce, but it remains fairly common, especially in the hills, on Bougainville and Buka. Its ability to survive in logged and degraded forest is poorly known. Lowland forest throughout the region is threatened by logging, and the cuckoo-shrike itself is considered Near-threatened; as a large proportion of the population appears to inhabit hill forest unsuitable for logging, however, its numbers may be declining relatively slowly. The Samoan Triller, confined to the two main Samoan islands, is generally uncommon and probably sedentary. Its survival requires the protection of primary forest on Upolu and Savai'i.

In Central Africa, Grauer's Cuckoo-shrike, the only entirely continental Near-threatened campephagid, is extremely local and uncommon. It has a restricted range in forested highlands of east-

*The **Samoan Triller** is restricted to the Samoan islands of Upolu and Savai'i, where it is generally uncommon and reliant on old-growth native forests for its survival. A combination of gradual habitat degradation, natural cyclones and poorly managed protected areas has raised concern for this species, which is therefore listed as Near-threatened. It is highly aberrant in several respects, being tiny, pale-eyed, sexually monochromatic and virtually patternless, on the basis of which it is sometimes placed in a monospecific genus:* Oscarornis. *Its taxonomic affinities deserve further study.*

[*Lalage sharpei*, Samoa. Photo: Roland Seitre]



ern DRCongo. Here, it is potentially at risk owing to the effects of forest clearance for slash-and-burn agriculture, and unregulated logging.

Reliable detailed information on the current status of most of the non-threatened species in the family is lacking, but many, especially those that are dependent on primary or mature forest, must have suffered extensive habitat loss. Species having a wider habitat tolerance, allowing them to thrive in modified forest, woodland and more open areas, as well as those which can occupy agricultural and urban habitats, generally appear to be relatively numerous and less vulnerable. Unfortunately, little or no information is available for a few very poorly known single-island endemics, including the Manus Cuckoo-shrike (*Coracina ingens*), the San Cristobal Cicadabird (*Coracina salomonis*) and the St Matthias Triller (*Lalage conjuncta*). The conservation status of the triller should perhaps be reassessed, in view of its very restricted range; confined to the St Matthias Group, in the Bismarck Archipelago, this species should probably be considered Vulnerable, at best.

A few of the Campephagidae have adapted well to modified or degraded habitats. In New Guinea, for example, the White-bellied Cuckoo-shrike is common and has invaded some urban areas, where it is locally abundant. It increased greatly in numbers following forest clearance in the Wau Valley, and it has invaded other highland areas in disturbed habitats. In Australia, it is similarly abundant in urban areas of the tropics. In contrast, the Ground Cuckoo-shrike, found only in Australia, is generally uncommon, and has declined in some places, possibly as a result of shrubland clearance. It may have benefited elsewhere, however, from the clearing of dense vegetation for agriculture, enabling it to extend into previously unsuitable areas.

In the Afrotropics, the four *Campephaga* and the four *Coracina* species are generally regarded as uncommon to locally common, but they must have suffered to some extent from habitat loss, and most of the forest-inhabiting species have fragmented distributions. It seems certain that the White-breasted Cuckoo-shrike, which inhabits mature woodland, has been adversely affected throughout its range by woodland clearance, especially for agriculture and charcoal production. The Grey Cuckoo-shrike, a widespread forest bird, is an altitudinal migrant and is thus able to tolerate a range of habitats. In consequence, if its breeding habitat is destroyed, it may have a better chance of natural relocation than would a sedentary forest species, while it may have benefited locally from increases in secondary forest and forest-edge habitats, and it also tolerates the presence of humans and occurs in gardens. The poorly known Petit's Cuckoo-shrike is considered uncommon to locally frequent. Although its numbers must surely have been reduced by forest destruction, it is known to survive in logged forest in Uganda.

The Madagascar Cuckoo-shrike (*Coracina cinerea*) is reasonably common in suitable habitat in Madagascar, but is uncommon in the Comoros. It is presumably at some degree of risk as a result of forest destruction, but few data are available.

*In 1993 the global population of the **Mauritius Cuckoo-shrike** amounted to a mere 260 pairs, but recent conservation action, involving the rehabilitation of native ecosystems on Mauritius, had already resulted in an increase to 300–350 pairs by 2000. Its numbers and range are still expanding, but it remains threatened by habitat loss, pollution, and predation by introduced mammals. The continued protection and management of Black River Gorges National Park, which covers most of the natural range of this species, would appear to be of critical importance.*

[*Coracina typica*, Mauritius. Photo: Roland Seitre]

*The only officially Endangered campephagid is the **Reunion Cuckoo-shrike**, a species confined to the Indian Ocean island of Reunion, where 60–160 pairs were estimated to survive in 2000 in a very small range (16 km²). It lives in mixed evergreen subtropical forest in the north-west of the island, often ranging into areas of low-stature heath, but it seems unable to expand its distribution or population despite ongoing conservation efforts. It is to be hoped that the 38-km² La Roche Ecrite Nature Reserve, established largely to conserve this species, will play a major role in ensuring its long-term survival.*

[*Coracina newtoni*, Reunion. Photo: Thomas Ghestemme/SEOR]

In Asia, numbers of the widespread Bar-bellied Cuckoo-shrike have probably been reduced throughout its range by the destruction of lowland forest. This species is apparently still common in the Philippines, but it is only rare to locally fairly common in the Malay Peninsula. Indeed, the subspecies in the latter region, *sumatrensis*, which occurs also, probably as a scarce resident, in Sumatra, is regarded as "Vulnerable", bordering on "Endangered", as a result of habitat destruction. Although the species is able to breed in secondary vegetation and isolated trees, it never occurs far from tall forest. Similarly, the Lesser Cuckoo-shrike is labelled as "Near-threatened" in the Malay Peninsula, again because of loss of its forest habitat. Farther east, on Halmahera, the Rufous-bellied Triller remains moderately common, despite its numbers having almost certainly been reduced by forest destruction. This campephagid's ability to occupy selectively logged forest suggests that it may not have suffered so serious a reduction as have some other species. Its relative, the Varied Triller, is locally common in suburbs and partly cleared country in Australia.

Although the Small Minivet is regarded as "Vulnerable" in the Malay Peninsula, because of a lack of records inland from the mangrove zone, it is still common in many other parts of South-east Asia and is very common in suitable habitat over the Indian Subcontinent. In contrast, the White-bellied Minivet, which was formerly regarded as common in Myanmar, is believed now to be uncommon there, and it is local and uncommon in India and Pakistan. One of the most widespread members of the family, the Scarlet Minivet, is designated as "Near-threatened" in the Malay Peninsula as a result of forest loss and fragmentation, but it appears still to be common elsewhere in South-east Asia, as well as in the Philippines, and from India to southern China.

Finally, one of the two flycatcher-shrikes, the Black-winged Flycatcher-shrike, is another species that is regarded as "Near-threatened" in Peninsular Malaysia. This is due to its relative scarcity on major slopes, and to its generally narrow habitat range.

No campephagid species are known to have become extinct in recent years, but three subspecies have disappeared. The nominate race of the Long-tailed Triller was restricted to Norfolk Island, east of Australia, where it probably occupied all wooded habitats and was common until 1941. Amazingly, however, it has not been seen since the year after that, 1942, and is considered extinct. This sudden and complete disappearance evidently coincides almost exactly with the arrival of black rats (*Rattus rattus*) on the island in the mid–1940s, and predation by the rats was probably the main cause of its extinction. Its disappearance also coincided, however, with the construction of an airport in the centre of the island, which involved the clearing of a large area of remnant native forest. The two other extinct taxa were both endemic on the island of Cebu, in the central Philippines. The subspecies *cebuensis* of the Bar-bellied Cuckoo-shrike was believed extinct in 1959 as a result of widespread deforestation on the island, while the subspecies *altera* of the Blackish Cuckoo-shrike (*Coracina coerulescens*) is considered also to be extinct, for the same reason.

There is no indication that members of this family are subject to significant mortality as a direct result of human actions. They are not hunted for food, nor are they targeted as pest species. With the exception of the globally threatened and extinct taxa mentioned in the preceding paragraphs, none of the species seems to suffer to any major extent from the adverse effects of introduced predators. In Australia, the Black-faced Cuckoo-shrike is occasionally killed by cats, and is sometimes a victim of road traffic. In addition, it sometimes dies as a result of flying into lighthouses while on passage, having been disoriented by the dazzling beams of light. Occasional lighthouse casualties are also reported for other migratory species, such as the Slender-billed Cicadabird and the Barred Cuckoo-shrike, while White-winged and Varied Trillers are very occasionally killed by vehicles.

Genus *PTEROPODOCYS* Gould, 1846

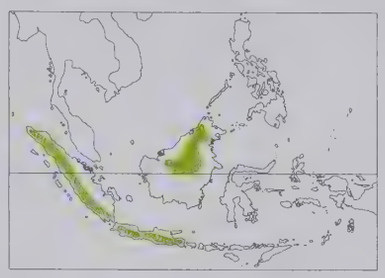
1. Ground Cuckoo-shrike

Pteropodocys maxima

French: Échenilleur terrestre **German**: Grundraupenfänger **Spanish**: Oruguero Terrestre
Other common names: Greybird, Caterpillar-catcher

Taxonomy. *Ceblepyris maxima* Rüppell, 1839, New Holland = New South Wales, Australia.
Sometimes placed in genus *Coracina*. N birds have been separated as race *pallida* on basis of slightly paler overall colour, but degree of difference from birds elsewhere in species' range is small (minor Gloger effect). Monotypic.
Distribution. Australia, mainly in interior.

Descriptive notes. 31–38 cm; 124–155 g. Large, slender and long-legged cuckoo-shrike; slightly forked tail unique in family. Has grey head, nape, mantle and breast, darker on ear-coverts and in front of and around eye; back to uppertail-coverts white, narrowly barred black; lesser upperwing-coverts grey, rest of wing black with greenish gloss, outer primaries narrowly edged white; rectrices black with white bases and narrow white tips, outer pair largely white; lower breast and belly white, finely barred black, undertail-coverts, underwing-coverts and axillaries white; iris buffy white; bill and legs dark grey. Easily separated from all other cuckoo-shrikes by striking contrast between grey head and back, black wings and tail, white underparts and lower back with fine dark barring, and whitish eye emphasized by darkish mask. Sexes alike. Juvenile is duller than adult, head to mantle lightly barred dusky, eye dark; immature not properly described, similar to adult. Voice. A loud, repeated "pee-oo" or "queel" delivered in flight; "chill-chill.....kee-lick", harsh "cool-ook" and muffled "woof" given when perched.
Habitat. Inhabits open, usually rather dry, lightly timbered country, including low eucalypt (*Eucalyptus*) woodland, acacia (*Acacia*) scrub and spinifex (*Triodia*), and grassy plains with scattered trees or shrubs; also visits trees along watercourses, as well as claypans, pastures and vineyards. Its preferred habitats tend to have ground cover sparse or absent; often occurs in areas of bare, stony ground.
Food and Feeding. Eats mainly adult and larval insects, including mantids (Mantodea), grasshoppers and locusts (Orthoptera), Phasmatodea, and ants (Hymenoptera); also arachnids. House Sparrow (*Passer domesticus*) also recorded as a prey item. Occasionally takes seeds and leaves. Prey taken on the ground; walks and runs with head jerking back and forth. Also hawks for flying insects from perch on stump or fence post. Usually forages in small groups.
Breeding. Recorded in all months, but mainly Aug–Dec/Jan, and after rains in arid regions. Nests communally; sometimes breeds co-operatively, helpers apparently the pair's young from previous season. Nest variable, from a shallow bowl to a deep cup, made of fine dry twigs, roots, bark and grass bound with cobwebs, loosely lined with soft vegetation, lichens or wool, placed 3–15 m above ground on horizontal branch or fork; occasionally builds on old nest of Magpie-lark (*Grallina cyanoleuca*), White-winged Chough (*Corcorax melanorhamphos*) or Apostlebird (*Struthidea cinerea*). Eggs 2–3, occasionally 4; no information on incubation period; chicks fed and cared for by both parents, often assisted by helpers, fledging period 29 days. Hatching success 67–73%; fledging success 40%.
Movements. Thought to be resident in some areas, and no large-scale seasonal movements apparent. Regarded as nomadic, with some types of movement that show no overall definite pattern. In S Murray Darling region, in SW New South Wales, an irregular visitor, apparently not influenced by local rainfall or temperature; at Coolup, in SW Western Australia, winter flocks occur fairly regularly and some stay for most of year.
Status and Conservation. Not globally threatened. Widespread, but generally regarded as uncommon; rarely found near coasts. Density of 0·5 birds/ha recorded on Nullarbor Plain, in Western Australia, in 1979. Declined in Victoria after human settlement, possibly because of clearing of shrublands. Has apparently extended its range into Queensland since 1935 and 1950, and in some parts of South Australia in 1930s and 1960s. Populations have reportedly declined in Murray–Mallee since mid-1970s.
Bibliography. Beruldsen (1980), Blakers *et al.* (1984), Boehm (1983), Brooker *et al.* (1979), Christidis & Boles (1994), Dickinson & Dekker (2002a), Hall (1974), Higgins *et al.* (2005), Immelmann (1962), Keast (1958), MacDonald (1988), McAllan & Bruce (1988), Morcombe (2000), Pizzey (1980), Schodde & Mason (1999), Serventy & Whittell (1976), Simpson & Day (1994), Slater *et al.* (1989), Trounson & Trounson (1987).



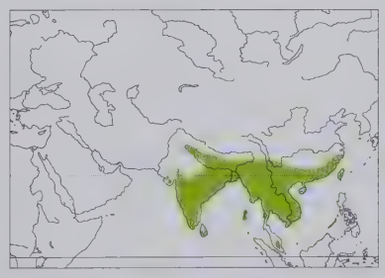
Genus *CORACINA* Vieillot, 1816

2. Sunda Cuckoo-shrike

Coracina larvata

French: Échenilleur de la Sonde **German**: Larvenraupenfänger **Spanish**: Oruguero de la Sonda
Other common names: Black-eared/Black-faced Cuckoo-shrike(!)

Taxonomy. *Ceblepyris larvata* S. Müller, 1843, Java.
Sometimes considered to form a species group with *C. temminckii*, *C. longicauda* and *C. parvula*, and has been treated as conspecific with last. Three subspecies recognized.
Subspecies and Distribution.
C. l. melanocephala (Salvadori, 1879) – Sumatra.
C. l. larvata (S. Müller, 1843) – Java.
C. l. normani (Sharpe, 1887) – Borneo.



Descriptive notes. 26–27 cm. Male nominate race is dark slaty-grey above, including upperwing-coverts, paler on side of head, dusky lower forehead and lores, slaty-black ear-coverts and feathers around eye; alula black, primary coverts and primaries black, edged slaty grey, secondaries similar but with broader grey edges, tertials slaty grey on outer webs, black on inner webs; rectrices black, tipped pale grey; throat dark grey merging into slaty grey rest of underparts, thighs darker; underwing-coverts and axillaries slaty grey; iris dark brown; bill and legs black. Differs from somewhat similar *C. personata* in having underwing-coverts grey (not white), bill smaller and narrower. Female resembles male, but smaller black mask, underwing-coverts barred grey and white, occasionally some barring on undertail-coverts. Juvenile is like female, but with whitish feather edges; immature also resembles female, but barring on underwing-coverts more pronounced. Race *melanocephala* male has entirely black head, juvenile very similar to adult nominate; adult *normani* has intermediate extent of black on head. Voice. Harsh, ringing whistles, "eeooo-eeooo-eeooo" or "shreeok", and a curious loud, wheezy song.
Habitat. Occupies humid forest, including mossy forest and pine (*Pinus*) forest; highlands, 850–2200 m.
Food and Feeding. Eats insects, including lepidopteran larvae, beetles (Coleoptera), grasshoppers (Orthoptera), crickets (Gryllidae), ants (Hymenoptera) and arachnids; also takes fruit. Forages singly or in pairs in treetops; sometimes joins mixed-species foraging flocks.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. In 1990s, was common in N & W mountain ranges of Sumatra, and in higher ranges in Borneo from Mt Kinabalu S to at least the Mueller Range (Kalimantan), but very local in Java. Occurs in Mount Kinabalu National Park, in Borneo, and Gunung Gede-Pangrango National Park, in Java.
Bibliography. Andrew (1985, 1992), Davison (1992), Hellebrekers & Hoogerwerf (1967), MacKinnon (1988), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Ripley (1941), Smythies (1999), Voous & van Marle (1949), Wilkinson, Dutson & Sheldon (1991).

3. Large Cuckoo-shrike

Coracina macei

French: Échenilleur de Macé **German**: Maskenraupenfänger **Spanish**: Oruguero de Macé
Other common names: Black-throated/Indian Cuckoo-shrike

Taxonomy. *Graucalus Macei* Lesson, 1831, Calcutta, India.
Forms a superspecies with *C. javensis*, *C. schistacea*, *C. personata*, *C. atriceps*, *C. fortis*, *C. welchmani*, *C. caledonica* and *C. novaehollandiae*, possibly also including *C. caeruleogrisea*; all were formerly treated as conspecific. All races of present species or, alternatively, only *larutensis* sometimes placed in *C. javensis*; the decision regarding to which of the two species *larutensis* should be assigned is critical to the resolution of relationships of these taxa, and further study needed. Differences in calls and morphology suggest that nominate race and *layardi* may represent a separate species. Eight subspecies provisionally recognized.
Subspecies and Distribution.
C. m. nipalensis (Hodgson, 1836) – Himalayas from Garhwal and W Nepal E to NE India (W Assam).
C. m. macei (Lesson, 1831) – C & S India from Garhwal E to West Bengal and Orissa, S to Travancore.
C. m. layardi (Blyth, 1866) – Sri Lanka (except NW lowlands).
C. m. andamana (Neumann, 1915) – Andaman Is.
C. m. siamensis (Stuart Baker, 1918) – Myanmar, S China (S Guizhou, W, NW & S Yunnan), Thailand (S to Isthmus of Kra) and S Indochina.
C. m. larutensis (Sharpe, 1887) – Peninsular Malaysia (from N Perak S to S Selangor and Pahang).
C. m. rexpineti (Swinhoe, 1863) – SE China (Guangxi, Guangdong, Fujian), Taiwan, N Laos and N Vietnam.
C. m. larvivora (Hartert, 1910) – Hainan I.

Descriptive notes. 23–30 cm. Very large cuckoo-shrike with massive, hooked bill. Male nominate race has upperparts, including upperwing-coverts, grey, paler on rump and uppertail-coverts; frontal line, lores and feathers around eye black, ear-coverts and side of face dark grey; alula black; primary coverts black, edged pale grey; primaries black, edged white; secondaries and tertials black, tipped white, with grey inner webs and white edges; rectrices black, tipped white, central pair grey, outer pair edged grey; chin blackish; cheeks and underparts grey, becoming white with grey bars on belly, white undertail-coverts; axillaries and underwing-coverts white with a few grey bars; iris brown to orange-brown; bill and legs dark brown to black. Female is lighter grey than male on upperparts, lores grey, ear-coverts dark grey, orbital feathering black; feathers from lower back to uppertail-

On following pages: 4. Javan Cuckoo-shrike (*Coracina javensis*); 5. Slaty Cuckoo-shrike (*Coracina schistacea*); 6. Wallacean Cuckoo-shrike (*Coracina personata*); 7. Moluccan Cuckoo-shrike (*Coracina atriceps*); 8. Buru Cuckoo-shrike (*Coracina fortis*); 9. North Melanesian Cuckoo-shrike (*Coracina welchmani*); 10. South Melanesian Cuckoo-shrike (*Coracina caledonica*); 11. Black-faced Cuckoo-shrike (*Coracina novaehollandiae*).

coverts, and greater upperwing-coverts, edged whitish, cheeks and entire underparts white, barred grey to blackish except from lower belly to undertail-coverts; rectrices browner than male's, with smaller white tips. Juvenile is brownish, heavily scaled whitish-buff, more mottled on underparts; immature resembles adult female, but with broader, paler edges on remiges and primary coverts. Races differ in barring of underparts, and in size and overall colour: *nipalensis* is largest and darkest, with very long wing, unbarred below, female weakly barred; *layardi* resembles nominate, but smaller (smallest race), wing short; *andamana* is pale, with reduced black on head, unbarred below, female weakly barred; *siamensis* has underpart barring absent in male, and reduced in female; *larutensis* is similar to previous, but male even darker grey, blacker on primaries and primary coverts, less white on tail tip; *rexpineti* is also similar, but darker on head and throat; *larvivora* is very like last, but bill more robust, wing shorter. Voice. Very noisy. Song (rarely heard) a quaint, melodious warble. Calls include loud, ringing parrot-like screech, "shkréét" (race *nipalensis*), longer, shriller "skréééaréél" (nominate, *layardi*), ringing "kleep" (*siamensis*); also has chuckling notes.

Habitat. Open, light woodland and secondary forest, including teak (*Tectona*), pine (*Pinus*) and oak (*Quercus*) forests, also scrub, groves, edges of clearings and plantations; occurs also in savanna, open and cultivated areas with scattered trees, and gardens. Lowlands and foothills, to 2400 m.

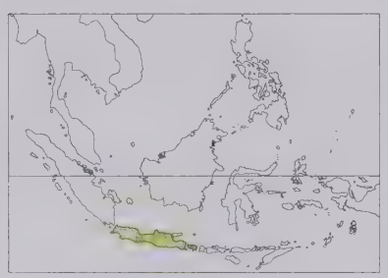
Food and Feeding. Eats large insects and their larvae, including mantids (Mantidae), weevils (Curculionidae), bugs (Hemiptera) and crickets (Gryllidae); also fruits and berries, especially figs (*Ficus*). Favours large trees, usually foraging in treetops but sometimes in bushes or among dead leaves on the ground. Occurs singly, in pairs or in loose flocks; searches methodically for insects, hopping and flying from branch to branch.

Breeding. Jan–Nov; May–Jun in Andaman Is, Apr–May in Myanmar and Mar–Apr in Peninsular Malaysia; apparently two breeding periods, Feb–Apr and Aug–Oct, in W India. Nest a shallow, flimsy saucer of twigs and grass with cobweb on outside, placed up to 18 m above ground in fork of horizontal branch in tree. Eggs 2–3. No other information.

Movements. In Himalayas and peninsular India, subject to local migrations in non-breeding season; also locally nomadic. In Nepal descends to lower altitudes in winter.

Status and Conservation. Not globally threatened. Rare in Himalayas of NE Pakistan and uncommon in Bhutan, but fairly common to common in Nepal, India, Sri Lanka and Bangladesh; common to fairly common in SE Asia. In Pakistan, has become a rare straggler around Murree and Islamabad, where formerly resident. Occurs in a number of protected areas, including e.g. Royal Chitwan National Park, in Nepal, Corbett and Nagarhole National Parks, in India, and Khao Yai National Park, in Thailand.

Bibliography. Ali (1969), Ali & Ripley (1996), Ali *et al.* (1996), Stuart Baker (1918), Cheng Tsohsin (1987), David & Gosselin (2002a), Deignan (1945, 1963), Dickinson & Dekker (2002a), Eames & Ericson (1996), Eames & Robson (1992), Étchécopar & Hüe (1983), Grimmett *et al.* (1998), Himmatsinhji (1969), Inskipp & Inskipp (1991), Kazmierczak (2000), Kuroda (1933), Lekagul & Round (1991), MacKinnon & Phillipps (2000), Madoc (1976), Medway & Wells (1976), Rasmussen & Anderton (2005), Ripley (1941, 1982), Roberts (1992), Round (1988), Smythies (1986), Stepanyan (1995), Voous & van Marle (1949), White & Bruce (1986).



4. Javan Cuckoo-shrike

Coracina javensis

French: Échenilleur de Java **German**: Javaraupenfänger **Spanish**: Oruguero de Java
Other common names: White-vented Greybird

Taxonomy. *Ceblephyris* [sic] *Javensis* Horsfield, 1821, Kepodang-sungu, Java.
Forms a superspecies with *C. macei*, *C. schistacea*, *C. personata*, *C. atriceps*, *C. fortis*, *C. welchmani*, *C. caledonica* and *C. novaehollandiae*, possibly also including *C. caeruleogrisea*; all were formerly treated as conspecific. All races of *C. macei* or, alternatively, only *larutensis* sometimes placed in present species; the decision regarding to which of the two species *larutensis* should be assigned is critical to the resolution of relationships of these taxa, and further study needed. Monotypic.

Distribution. Java and Bali.

Descriptive notes. 28 cm. Male has head and upperparts, including lesser upperwing-coverts, lead-grey; narrow frontal band, lores, face to ear-coverts and above eye, and chin and upper throat, grey-black; median and greater wing-coverts lead-grey, edged paler; alula and primary coverts black, margined grey; primaries and secondaries black, edged whitish, secondaries with largely grey outer webs; tertials grey with blackish inner webs; rectrices black, tipped white, central pair grey, tipped white, outermost pair broadly edged white; lower throat, breast and flanks grey, slightly paler than upperparts, becoming white from centre of belly to vent, sometimes faint grey barring on lateral undertail-coverts; axillaries and underwing-coverts white; iris red-brown to red; bill black; legs black to dark brown. Distinguished from very similar *C. macei* by slightly darker grey colour, blacker primaries and primary coverts, less white on tail tip. Female is like male but paler grey, with grey-black on head extending only from lores to behind eye and side of face, variable grey barring from lower breast and flanks to undertail-coverts. Juvenile is pale grey above and from chin to breast, with dull brown feather tips and white fringes (scaled pattern), primaries and secondaries edged and tipped white, underparts greyish-white with brown scaling/barring; immature resembles adult female, but more extensive grey barring on underparts. Voice. Loud, piercing whistle, "pee-eeo-pee-eeo", and "tweer" or "twee-eet".

Habitat. Open forest, including forest edge and edges of clearings, and savanna. Lowlands, to 1500 m.

Food and Feeding. No information on diet; probably similar to that of *C. macei*. Forages in tops of tallest trees, often at edges of clearings.

Breeding. No information.

Movements. None recorded.

Status and Conservation. Not globally threatened. Not well known. Was regarded as widespread and fairly common in 1990s. Occurs in Baluran National Park, in Java.

Bibliography. van Balen (1999), Dickinson & Dekker (2002a), Dupond (1942), Hawa (1985), Hellebrekers & Hoogerwerf (1967), Inskipp *et al.* (1996), Jeyarajasingam & Pearson (1999), Kuroda (1933), MacKinnon (1988), MacKinnon & Phillipps (1993), Ripley (1941), Robinson (1928), Robson (2000), Sargeant (1997), Sibley & Monroe (1990), Strange (2001, 2002), Voous & van Marle (1949), Wells (2005), White & Bruce (1986).

5. Slaty Cuckoo-shrike

Coracina schistacea

French: Échenilleur schistacé **German**: Schieferraupenfänger **Spanish**: Oruguero Pizarroso
Other common names: Sula Cuckoo-shrike

Taxonomy. *Artamides schistaceus* Sharpe, 1878, Sula Islands.
Forms a superspecies with *C. macei*, *C. javensis*, *C. personata*, *C. atriceps*, *C. fortis*, *C. welchmani*, *C. caledonica* and *C. novaehollandiae*, possibly also including *C. caeruleogrisea*; all were formerly treated as conspecific. Birds from Banggai I sometimes separated as race *petersi*, but considered indistinguishable from those in rest of species' range. Monotypic.

Distribution. Islands off E Sulawesi: Banggai Is (Peleng, Banggai) and Sula Is (Taliabu, Seho, Mangole, Sanana).

Descriptive notes. 31–32 cm. Male is generally slaty grey, with glossy black head, neck, chin and throat; upperwing-coverts and remiges slaty grey, primaries edged paler; tail black; underwing-coverts and undertail-coverts slaty grey; iris dark brown; bill and legs black. Differs from *C. caledonica* in paler general coloration, more extensive black on head. Female lacks black on head and throat, except for dull blackish lores and feathers in front of eye. Juvenile and immature undescribed. Voice. A series of slightly downslurred, nasal, whistling notes, emitted at 1 note per second; also short, unmusical, slightly metallic notes.

Habitat. Primary, secondary and selectively logged lowland forest, degraded forest, lightly wooded swampland and cultivation, and tall mangrove forest.

Food and Feeding. Food includes caterpillars, small lizards and fruit. Forages mainly at 10 m or higher above the ground.

Breeding. No information.

Movements. Nothing recorded.

Status and Conservation. Not globally threatened. Restricted-range species: present in Banggai and Sula Islands EBA. Locally not uncommon in Banggai Is. In Sula Is, common on Taliabu and Mangole, but uncommon on Sanana.

Bibliography. Andrew (1992), Coates & Bishop (1997), Collar & Andrew (1988), Davidson *et al.* (1995), Dickinson & Dekker (2002a), Dickinson *et al.* (2002a), Ripley (1941), Sujatnika *et al.* (1995), Voous & van Marle (1949), White & Bruce (1986).

6. Wallacean Cuckoo-shrike

Coracina personata

French: Échenilleur wallacéen **German**: Wallaceraupenfänger **Spanish**: Oruguero de Wallacea
Other common names: Timor/Lesser Sunda Cuckoo-shrike (*personata*); Kai Cuckoo-shrike (*pollens*)

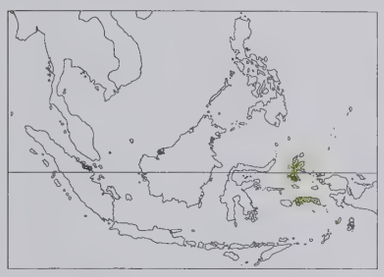
Taxonomy. *Ceblepyris personata* S. Müller, 1843, Timor.
Forms a superspecies with *C. macei*, *C. javensis*, *C. schistacea*, *C. atriceps*, *C. fortis*, *C. welchmani*, *C. caledonica* and *C. novaehollandiae*, possibly also including *C. caeruleogrisea*; all were formerly treated as conspecific. Has been suggested that *C. fortis* is conspecific with present species. Races *pollens* and *unimodus* sometimes treated as representing a separate species; *floris* and *sumbensis* also sometimes given species status. Putative race *lettiensis* (from Leti, Moa and Sermata), supposedly with weaker bill, considered insufficiently distinct from nominate. Six subspecies recognized.

Subspecies and Distribution.
C. p. floris (Sharpe, 1878) – W Lesser Sunda Is (Sumbawa, Komodo, Rinca, Flores, Besar).
C. p. sumbensis (A. B. Meyer, 1882) – Sumba.
C. p. alfrediana (Hartert, 1898) – E Lesser Sundas (Lomblen, Alor).
C. p. personata (S. Müller, 1843) – Roti, Semau, Timor, Wetar, Romang, Leti, Moa and Sermata.
C. p. unimodus (P. L. Sclater, 1883) – Tanimbar Is (Yamdena, Larat, Loedoe).
C. p. pollens (Salvadori, 1874) – Kai Is.

Descriptive notes. 32 cm. Male nominate race is generally slaty grey above; frontal line, lores, eye region, side of face and neck, ear-coverts, chin and throat black with greenish gloss; scapulars, upperwing-coverts and remiges black, edged slaty grey (edges broader on secondaries and tertials); tail blackish, feathers with grey tips and wash on outer webs; underparts (including undertail-coverts) slaty grey, axillaries and underwing-coverts white; iris, bill and legs black. Differs from *C. fortis* in having more black on head, darker abdomen and undertail-coverts. Female is like male, but lacks black on side of face and throat, has underwing-coverts and axillaries buffy white. Juvenile and immature undescribed. Race *alfrediana* is much paler than nominate, with white lower belly and undertail-coverts, lacks black on face and throat; *floris* is rather darker grey than previous, also has white lower belly and undertail-coverts, but male has black lores, face and throat; *sumbensis* resembles previous but larger, much paler, with more white on belly; *unimodus* is very dark slaty, including on underwing-coverts, belly and undertail-coverts, has black face and throat; *pollens* is like last but even darker, with blackish undertail-coverts. Voice. A series of long, monosyllabic piping whistles; also a long, plaintive "weeeeer", 2–3 upslurred buzzy notes repeated every 2–3 seconds, and nasal, querulous, squabbling notes.

Habitat. Mainly occurs in primary lowland and hill forest, but also in woodland, monsoon scrub, savanna and various forms of cultivation; avoids open areas and eucalypt (*Eucalyptus*) woodland. Nominate race occurs in woodland from sea-level to 2200 m; *floris* in woodland and cultivation up to 1400 m.

Food and Feeding. No information available on food; presumably insectivorous. Forages inconspicuously in forest canopy and in crowns of isolated trees.



Breeding. Breeds May–Jun on Sumbawa and Flores (race *floris*); nestlings in Mar on Roti (nominate). No other information.
Movements. Apparently sedentary; some local movements possible.
Status and Conservation. Not globally threatened. Widespread and locally common on Flores; moderately common on Komodo, Timor and Tanimbar Is; sparse on Sumba; very uncommon on Kai Is.
Bibliography. Andrew (1992), Coates & Bishop (1997), Dickinson & Dekker (2002a), Johnstone & Jepson (1996), Johnstone *et al.* (1996), Jones *et al.* (1994), Mason & McKean (1982), Ripley (1941), Schodde & Mason (1999), Strange (2001), Trainor (2002a, 2002b), Voous & van Marle (1949), White & Bruce (1986).

7. Moluccan Cuckoo-shrike

Coracina atriceps

French: Échenilleur des Moluques **Spanish**: Oruguero Moluqueño
German: Molukkenraupenfänger
Other common names: Seram Cuckoo-shrike

Taxonomy. *Ceblepyris atriceps* S. Müller, 1843, Celebes; error = Seram.
Forms a superspecies with *C. macei*, *C. javensis*, *C. schistacea*, *C. personata*, *C. fortis*, *C. welchmani*, *C. caledonica* and *C. novaehollandiae*, possibly also including *C. caeruleogrisea*. Two subspecies recognized.
Subspecies and Distribution.
C. a. magnirostris (Bonaparte, 1850) – N Moluccas (Ternate, Halmahera, Kasiruta, Bacan).
C. a. atriceps (S. Müller, 1843) – Seram (S Moluccas).

Descriptive notes. 32–35 cm. Male nominate race has head, neck, upper mantle, chin, throat and breast black with bluish gloss; rest of upperparts, including upperwing-coverts, light slaty grey, paler on rump and uppertail-coverts; alula, primary coverts and primaries black, edged ashy grey, rest of remiges black, outer webs grey; rectrices black, tipped ashy, central pair dark ashy brown, tipped black; abdomen and undertail-coverts pure white, flanks and thighs washed bluish-grey, underwing-coverts and axillaries white; iris dark brown; bill black, legs slaty black. Female has black of head, neck, throat and breast replaced by sooty grey, or throat ashy, breast lighter ashy and lores black. Juvenile and immature undescribed. Race *magnirostris* is larger and darker grey overall than nominate, with hood extending further down on both upperparts and underparts, with less clear-cut edge. Voice. Harsh, staccato dry chatter, occasionally given alternately by two individuals.
Habitat. Primary forest, mainly in hills; also tall secondary and selectively logged forest, coastal casuarina (*Casuarina*) groves and woodland, lightly wooded cultivation; occasionally in mangroves. Ascends to 1200 m on Halmahera and Seram.
Food and Feeding. Food not recorded. Frequents upper tree levels, including the lower canopy, and crowns of subcanopy trees.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Seram EBA and Northern Maluku EBA. Widespread and common on Halmahera; locally common on Seram, mainly in the hills. Poorly known species.
Bibliography. Andrew (1992), Bowler & Taylor (1989), Coates & Bishop (1997), Dickinson & Dekker (2002a), Inskipp *et al.* (1996), Isherwood *et al.* (1997), Michaux (1998), Ripley (1941), Strange (2001), Sujatnika *et al.* (1995), Voous & van Marle (1949), White & Bruce (1986).

8. Buru Cuckoo-shrike

Coracina fortis

French: Échenilleur de Buru **German**: Bururaupenfänger **Spanish**: Oruguero de Buru

Taxonomy. *Graucalus fortis* Salvadori, 1878, Buru Island, South Moluccas.
Forms a superspecies with *C. macei*, *C. javensis*, *C. schistacea*, *C. personata*, *C. atriceps*, *C. welchmani*, *C. caledonica* and *C. novaehollandiae*, possibly also including *C. caeruleogrisea*; all were formerly treated as conspecific. It has been suggested that present species may be conspecific with *C. personata*, but treatment as a separate species seems preferable on grounds of its geographical isolation and also from the fact that it approaches *C. caeruleogrisea* in appearance. Monotypic.
Distribution. Buru, in S Moluccas.

Descriptive notes. 35·5 cm. Male is grey above, with black lores, eye region and chin; rectrices blackish, outermost grey-tipped, centre two as upperparts; throat and underparts grey, paler than upperparts, undertail-coverts ashy white; iris dark; bill and legs black. Differs from *C. personata* in larger size, less extensive black on head, slightly paler abdomen and undertail-coverts. Female is like male, but lores dusky, undertail-coverts purer white. Juvenile and immature undescribed. Voice. No information.
Habitat. Lowland, montane and monsoon forest, including disturbed areas, to 1500 m.
Food and Feeding. No information.
Breeding. Nestling recorded in early Feb. No other information.
Movements. None reported.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Buru EBA. Confined to a single island. Poorly known. Was regarded as unobtrusive but not particularly rare in 1981–1982, but by 1989 was sufficiently rarely encountered for no density estimates to be possible. In 1995–1996 only 14 birds were found, at three localities, suggesting that it is very local. Probably little affected by recent habitat changes, because it occurs in disturbed habitat and appears to prefer higher-altitude forest with open understorey.
Bibliography. Andrew (1992), Coates & Bishop (1997), Collar & Andrew (1988), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Collar, Mallari & Tabaranza (1999), Dickinson & Dekker (2002a), Inskipp *et al.* (1996), Jepson (1993), Michaux (1998), Ripley (1941), Stattersfield & Capper (2000), Sujatnika & Jepson (1995), Sujatnika *et al.* (1995), Voous & van Marle (1949), White & Bruce (1986).

9. North Melanesian Cuckoo-shrike

Coracina welchmani

French: Échenilleur de Welchman **Spanish**: Oruguero de Welchman
German: Solomonen-Raupenfänger

Taxonomy. *Graucalus (Artamides) welchmani* Tristram, 1892, Bugotu (= Santa Isabel), Solomon Islands.
Forms a superspecies with *C. macei*, *C. javensis*, *C. schistacea*, *C. personata*, *C. atriceps*, *C. fortis*, *C. caledonica* and *C. novaehollandiae*, possibly also including *C. caerulogrisea*; all were formerly treated as conspecific. In recent decades, present species has normally been treated as conspecific with *C. caledonica*, but the two show notable differences in plumage, sexual dichromatism, iris colour, voice, and habitat preferences; all these factors, combined with significant geographical gap of c. 1000 km of ocean between the two groups, suggest it is more appropriate to revert to their earlier treatment as two separate species. Four subspecies recognized.
Subspecies and Distribution.
C. w. bougainvillei (Mathews, 1928) – Bougainville I.
C. w. kulambangrae Rothschild & Hartert, 1916 – New Georgia Group (Kolombangara, New Georgia and Vangunu), in Solomon Is.
C. w. welchmani (Tristram, 1892) – Santa Isabel.
C. w. amadonis Cain & Galbraith, 1955 – Guadalcanal.

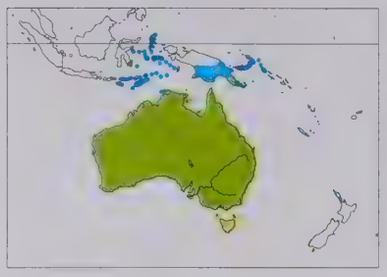
Descriptive notes. 30–33 cm; 133–165 g. A large cuckoo-shrike, with large bill and moderately long tail. Male nominate race has dark slaty-grey head and upperparts, including upperwing-coverts; glossy black on lores, feathers around eye, malar area, chin and throat (sometimes to upper breast), black extending back over eye to form distinct superciliary streak; remiges with ashy-grey outer webs and ashy-brown inner webs, primaries edged whitish; rectrices black, outer feathers narrowly tipped white; entire underparts, including undertail-coverts, underwing-coverts and axillaries, slaty grey; iris dark brown; bill and legs black. Differs from *C. caledonica* in smaller size, greater extent of black on head, upperparts and anterior underparts (thus, also greater degree of sexual dimorphism), presence of gloss on black areas, remaining areas darker grey, dark iris. Female is similar to male, but lacks black on head (except in region of ear-coverts) and throat. Juvenile and immature undescribed. Races differ mainly in depth of coloration and extent of black: *bougainvillei* is paler above than nominate, crown darker than upperparts, black below extends to upper breast; *kulambangrae* is darker above, crown again darker than upperparts, black below extends only to throat, tail proportionately longer; *amadonis* is smallest race, also darkest, with black extending to upper back on male, very dark below, black on male extending to breast, only slightly paler on belly. Voice. Call on Bougainville (race *bougainvillei*) a squeaky "mee-ahh-ahh", on Guadalcanal (*amadonis*) a harsh, creaking "squeei" like a kitten's mew or a squeaky gate; on Kolombangara (*kulambangrae*) most common calls are a long descending whistle reminiscent of a falling bomb, and a shrill creaking 'chi', often repeated. All races have loud, harsh contact and aggression calls and chatters.
Habitat. Forest, usually on hills or mountains, but occasionally reported from foothills or lowlands on Bougainville; often in lowlands on Kolombangara, where more common in mangroves and coastal forest, often degraded forest.
Food and Feeding. Eats large insects and fruit. Forages in pairs, occasionally in small groups, at outer edge of canopy, moving slowly; shuffles its wings when foraging. No other information.
Breeding. Nest-building observed in mid-Aug on Kolombangara. No other information.
Movements. None reported.
Status and Conservation. Not globally threatened. Restricted-range species: present in the Solomon Group EBA. Uncommon to rare; very few records away from Kolombangara, where locally not uncommon. May possibly have suffered some reduction in numbers in lowlands as a result of clearance and degradation of forest habitat, but normally lives in higher-lying areas.
Bibliography. Buckingham *et al.* (1995), Cain & Galbraith (1956), Coates (1990), Galbraith & Galbraith (1962), Dutson (2005d), Hadden (1981), Kratter *et al.* (2001), Mayr (1955, 1978), Ripley (1941), Webb (1992), White & Bruce (1986).

10. South Melanesian Cuckoo-shrike

Coracina caledonica

French: Échenilleur calédonien **Spanish**: Oruguero de Melanesia
German: Melanesienraupenfänger

Taxonomy. *Corvus caledonicus* J. F. Gmelin, 1788, New Caledonia.
Forms a superspecies with *C. macei*, *C. javensis*, *C. schistacea*, *C. personata*, *C. atriceps*, *C. fortis*, *C. welchmani* and *C. novaehollandiae*, possibly also including *C. caerulogrisea*; all were formerly treated as conspecific. In recent decades, present species has normally been treated as conspecific with *C. welchmani*, but the two show notable differences in plumage, sexual dichromatism, iris colour, voice, and habitat preferences; all these factors, combined with significant geographical gap of c. 1000 km of ocean between the two groups, suggest it is more appropriate to revert to their earlier treatment as two separate species. Four subspecies recognized.
Subspecies and Distribution.
C. c. thilenii (Neumann, 1915) – Vanuatu (Espíritu Santo, Malo, Malakula).
C. c. seiuncta Mayr & Ripley, 1941 – Erromango, in S Vanuatu.
C. c. lifuensis (Tristram, 1879) – Loyalty Is (Lifou).
C. c. caledonica (J. F. Gmelin, 1788) – New Caledonia.
Descriptive notes. 30–35 cm; 117–180 g. Male nominate race has slaty-grey head and upperparts, including upperwing-coverts; black forehead, lores, feathers around eye, and chin; remiges with



ashy-grey outer webs and ashy-brown inner webs, primaries edged whitish; rectrices black, outer feathers narrowly tipped white; throat and entire underparts, including undertail-coverts, underwing-coverts and axillaries, dark slaty grey; iris yellowish-white; bill and legs black. Differs from *C. welchmani* in larger size, smaller extent of black on head and throat (thus, also lesser degree of sexual dimorphism), lack of gloss on black areas, pale iris. Female is paler overall, more ashy grey, than male, with dusky (not black) lores. Juvenile has belly and underwing-coverts barred paler, tertials with subterminal white spots, rectrices edged and spotted white; immature undescribed. Races differ in general colour tone of plumage, eye colour (dark brown to red-brown in most races) and length of bill and tarsus: *thilenii* is bluish-slate above, blackish-slate on undertail-coverts and underwing-coverts. Voice. Loud whistle, "zweee" or "tseeoo", like that of Common Starling (*Sturnus vulgaris*), usually upslurred and often repeated; song a series of chattering guttural "kwa-kwawa-kwawa" or "kwawa-wa—seee—kwawa-wa—seee" phrases.
Habitat. Forest; fairly common in savanna, cultivated areas, humid forest. Lowlands; absent above 1100 m.
Food and Feeding. Eats insects and fruit. No other information.
Breeding. No information.
Movements. None reported.
Status and Conservation. Not globally threatened. Restricted-range species: present in the Vanuatu and Temoutu EBA and New Caledonia EBA. Poorly known; no recent information on status. Has presumably suffered population reductions as a result of the clearance and degradation of forest habitat.
Bibliography. Birchenough *et al.* (2003), Bregulla (1992), Doughty *et al.* (1999), Dutson (2005d), Hannecart & Létocart (1983), Mayr (1978), Michaux (1998), Ripley (1941), Vuilleumier & Gochfeld (1976), White & Bruce (1986).

11. Black-faced Cuckoo-shrike

Coracina novaehollandiae

French: Échenilleur à masque noir **Spanish**: Oruguero Carinegro
German: Schwarzgesicht-Raupenfänger
Other common names: Large(!)/Greater/White-vented Cuckoo-shrike, Australian Greybird

Taxonomy. *Turdus novae Hollandiae* J. F. Gmelin, 1789, "terra van Diemen" = Adventure Bay, Tasmania.
Forms a superspecies with *C. macei*, *C. javensis*, *C. schistacea*, *C. personata*, *C. atriceps*, *C. fortis*, *C. welchmani* and *C. caledonica*, possibly also including *C. caeruleogrisea*; all were formerly treated as conspecific. Australian populations of nominate race and *melanops* exhibit continent-wide cline of increasing body size N to S. Birds from (N Australia) described as race *didimus*, but considered indistinguishable from *melanops*. Three subspecies recognized.
Subspecies and Distribution.
C. n. subpallida Mathews, 1912 – breeds WC Australia (Pilbara); non-breeding possibly Lesser Sundas and Kai Is.
C. n. melanops (Latham, 1801) – breeds SW, S, E & N Australia and main offshore islands, also locally SE New Guinea (Port Moresby region); non-breeding Moluccas, Lesser Sundas, and E New Guinea E to W Solomons.
C. n. novaehollandiae (J. F. Gmelin, 1789) – breeds Tasmania and islands in Bass Strait (King I, Furneaux Group); non-breeding SE Australia.
Descriptive notes. 32–35 cm; 89–148 g. Male nominate race is light dove-grey on head, upperparts and upperwing-coverts; greenish-black from forecrown to eye and on side of head, neck and throat; alula and primary coverts black, edged light grey; remiges black, edged and tipped white; tail black, feathers tipped white, central two feathers grey; underparts pale grey, white undertail-coverts and underwing-coverts; iris, bill and legs black. Sexes similar. Juvenile has forehead blackish, mixed with grey, lores, feathers around eye and ear-coverts black, throat and cheeks white, throat

with arrow-shaped black bars, head and upper breast with fine crescentic grey barring; immature similar to adult, but black on head confined to mask (from bill through eye to ear-coverts), chin and throat whitish, eye dark brown. Race *subpallida* has much paler grey upperparts, very pale grey breast and whitish belly; *melanops* is similar to nominate but has longer bill, S populations also longer-winged. Voice. A cheerful, repeated "shri-lunk", usually in flight, also a plaintive "plee-urk" and a loud, musical rolling, purring or churring note; also harsh "kreer" and "skair".
Habitat. Open forest, forest edges, clearings and secondary growth, savanna woodland, eucalypt (*Eucalyptus*) woodland in dry areas, and parks and gardens; also cultivation with trees, littoral woodland, mangroves, casuarina (*Casuarina*) groves and ploughed paddocks. Mainly in coastal areas and lowlands, including small islands, but recorded to 1830 m in New Guinea.
Food and Feeding. Eats wide variety of invertebrates, including grasshoppers (Orthoptera), dragonflies (Odonata), cockroaches (Blattodea), termite alates (Isoptera), mantids (Mantodea), lepidopteran larvae, adult and larval beetles (Coleoptera) and bugs (Hemiptera), wasps and ants (Hymenoptera), spiders (Araneae) and worms (Annelida). Vegetable matter, seeds, and fruit such as mistletoe (Loranthaceae), figs (*Ficus*) and berries (*Olea*, *Exocarpus*, *Lycium*) also taken. Forages in foliage and branches of trees, and under bark. Takes most prey by sallying, often sally-pouncing to ground; also gleans, hovers over trees or low over grass, and sometimes (especially migrants) feeds on the ground.
Breeding. May–Feb in N Australia, Aug–Jan in S, and Aug and Oct–Dec in Tasmania, after rains in arid regions; Sept–Dec in New Guinea. Nest built by both sexes, a small, neat, shallow cup of fine twigs, bark, dry grass and needles (especially casuarina needles), lined with finer materials and bound with spider webs, placed usually 8–20 m above ground, sometimes down to 2 m, on horizontal fork of tree branch; parents defend nest by diving at human intruder, alighting between attacks and raising feathers of crown, back and rump, fanning tail and undertail-coverts, and opening beak to show pink-red palate. Eggs 2–3; incubation by both sexes, period not documented; both also care for chicks, which fledge at 22–26 days. Hatching success 54·4–70%; fledging success 30·1%.
Movements. Tasmanian populations (nominate race) cross Bass Strait mainly in Mar–Apr to non-breeding grounds in SE mainland Australia, N to at least R Murray, and recorded also SE New Guinea (Port Moresby region); return passage mainly Sept–Oct. E Australian populations (*melanops*) make regular seasonal movements, most pronounced in Mar–May, wintering Apr–Nov N to N Australia, New Guinea, Bismarck Archipelago and W Solomon Is (very uncommon), and W to S & E Sulawesi subregion, Moluccas and Lesser Sundas of Wallacea; return passage noted mainly Aug–Oct; Wallacea specimens of this race cover all months except Dec–Jan and Mar, and seems likely that migrants may breed there sporadically. W race *subpallida* may migrate to Lesser Sundas and Kai Is; records need confirmation. In Australia, gathers in large numbers before migrating; probably moves to New Guinea on broad front across Coral Sea. Some movements in Australia described as nomadic, but the nature of these not known. Occasional visitor to New Zealand (mostly during Mar–Apr and Jun–Sept; one record in Jan) and Lord Howe I; rare vagrant in New Caledonia.
Status and Conservation. Not globally threatened. Widespread and locally common in Australia; locally common in SE New Guinea. Densities in eucalypt woodland 0·03–0·25 birds/ha; in eucalypt forest 0·01–1 birds/ha. In Australia, possibly not adversely affected by logging, as it occurs in various age-classes of forest. Locally common in S Papua New Guinea (but scarce in N) in non-breeding season.
Bibliography. Aston (1992), Beehler *et al.* (1986), Beruldsen (1980), Blakers *et al.* (1984), Christidis & Boles (1994), Clancy (1985), Coates (1990, 2001), Coates & Bishop (1997), Debus (1985), Diamond (1972), Dickinson & Dekker (2002a), Doughty *et al.* (1999), Filardi *et al.* (1999), Hall (1974), Hardy (1986), Heather & Robertson (1997), Higgins *et al.* (2005), Hobbs (1986), Keast (1958), Liddy (1990), Marchant (1978, 1985a), Mason & McKean (1982), Mayr (1955), Mayr & Rand (1937), McClure (1998), McCulloch (1970), Mees (1961, 1982), Pizzey (1980), Rand & Gilliard (1967), Rensch (1931), Ripley (1941), Schodde & Mason (1999), Serventy & Whittell (1976), Sutton & Filippich (1983), Voous & van Marle (1949), White (1938), White & Bruce (1986), Wood (1994).

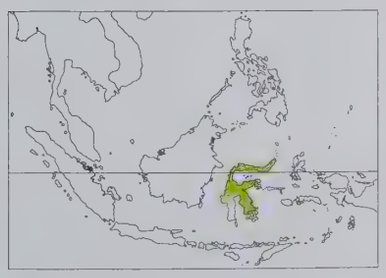
12. Stout-billed Cuckoo-shrike

Coracina caeruleogrisea

French: Échenilleur à gros bec **Spanish**: Oruguero Picogrueso
German: Dickschnabel-Raupenfänger
Other common names: Blue-grey Cuckoo-shrike, Stout-billed Greybird

Taxonomy. *Campephaga caeruleogrisea* G. R. Gray, 1858, Aru Islands.
Possibly belongs to the superspecies comprised by *C. macei*, *C. javensis*, *C. schistacea*, *C. personata*, *C. atriceps*, *C. fortis*, *C. welchmani*, *C. caledonica* and *C. novaehollandiae*. Three subspecies recognized.
Subspecies and Distribution.
C. c. strenua (Schlegel, 1871) – W & C New Guinea (E to Wahgi Valley), including Yapen I.
C. c. caeruleogrisea (G. R. Gray, 1858) – SC New Guinea and Aru Is.
C. c. adamsoni Mayr & Rand, 1936 – E New Guinea.



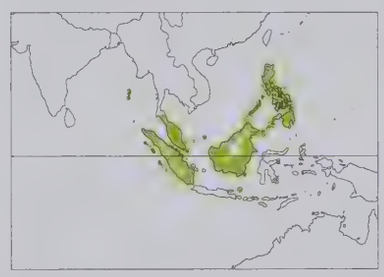
Descriptive notes. 33–37 cm; male 127–170 g, female 116–142 g. Male nominate race is blue-grey above, including upperwing-coverts and tertials, brighter blue on head; chin, and feathers at base of forehead and from bill to eye, black; alula and primary coverts black; primaries black, narrowly edged bluish-grey, secondaries with bluish-grey outer webs and black inner webs; tail black, central two feathers bluish-grey, outer two blackish-brown; bluish-grey below, duller than upperparts; axillaries and underwing-coverts pale rufous and whitish-buff; iris chestnut to blackish-brown; bill and legs black. Distinguished from similar *C. boyeri*, which also has rufous underwing, by much larger size, larger and heavier bill, no black on throat. Female is like male but slightly duller, lacks black on head. Newly fledged juvenile is whitish-grey, with some dark grey on head, breast and wings, whitish upperwing-coverts; immature like female but duller, has buffy-white tips on rectrices. Races differ in size and overall colour, nominate smallest and palest: *strenua* is darkest, intermediate in size; *adamsoni* is largest, has darkest underwing-coverts. Voice. Slightly musical but harsh "shhhyyun-eshhhyuway"; also short chirp, soft mewing slur, soft rasp and harsh buzzy notes.
Habitat. Inhabits forest, forest edges, tall secondary growth and disturbed habitats. In New Guinea, mainly in lowlands, hill forest and lower mountains; present from sea-level up to 1700 m, rarely up to 2450 m.
Food and Feeding. Eats large insects, including weevils (Curculionidae) and other beetles (Coleoptera), also cockroaches (Blattodea) and lepidopteran larvae; fruit and small lizards also taken. Forages in pairs or small parties. Moves slowly, deliberately and inconspicuously through upper levels of trees, mostly perching and walking on larger limbs.
Breeding. Nestling in Nov and fledglings seen in Jan and Apr, indicating breeding late in dry season and early and late in wet season. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Widely distributed; generally uncommon, but locally fairly common. Appears tolerant of disturbed habitats.
Bibliography. Andrew (1992), Beehler (1978a), Beehler *et al.* (1986), Coates (1990, 2001), Diamond (1972), Gilliard & LeCroy (1961), Gregory (1995), Gyldenstolpe (1955), Mack *et al.* (2000), Mayr & Rand (1937), Rand (1942), Rand & Gilliard (1967), Ripley (1941, 1964), Schmid (1993), Strange (2001), Voous & van Marle (1949), White & Bruce (1986).

13. Cerulean Cuckoo-shrike

Coracina temminckii

French: Échenilleur de Temminck **Spanish**: Oruguero de Temminck
German: Temminckraupenfänger
Other common names: Sulawesi/Celebes/Temminck's Cuckoo-shrike

Taxonomy. *Ceblepyris temminckii* S. Müller, 1843, Gorontalo, north Sulawesi.
Sometimes thought to form a species group with *C. larvata*, *C. longicauda* and *C. parvula*. Race *rileyi* possibly indistinguishable from *tonkeana*. Three subspecies tentatively recognized.
Subspecies and Distribution.
C. t. temminckii (S. Müller, 1843) – N Sulawesi mountains.
C. t. rileyi Meise, 1931 – mountains of C & SE Sulawesi.
C. t. tonkeana (A. B. Meyer, 1903) – mountains of E Sulawesi.



Descriptive notes. 30·5 cm. Distinctive. Male nominate race is almost entirely greyish-azure with cobalt hue, especially on wings and tail; lores and base of forehead blackish with blue gloss, inner webs of primaries and rectrices blackish; underparts, including underwing-coverts and axillaries, like upperparts; iris white or blue-white; bill and legs black. Sexes alike. Juvenile is predominantly dark grey, with pale cross-barring, white subterminal spots on tertials, white edges and spots on rectrices; immature undescribed. Races vary only slightly: *tonkeana* is slightly bluer (less violet-looking) dorsally and paler below than nominate; *rileyi* is slightly greyer than previous. Voice. Vocal, with distinctive and unusual calls which include harsh, nasal upslurred "ssssssschu", sometimes preceded by 2 short, dry notes; 5–7 loud, high-pitched whistles, "pi pí pí pí pí", rather like those of a cuckoo (Cuculidae); short, thin high-pitched note given in flight.
Habitat. Primary forest and tall secondary forest in foothills and mountains, at 100–2200 m, mainly above 500 m; occasionally in pine (*Pinus*) plantations.
Food and Feeding. Food not recorded; presumably insects. Generally moves in small parties of up to eight birds, foraging at middle levels, in subcanopy and in tree crowns. Gleans food from large, lateral branches, vines, trunks and undersides of leaves.
Breeding. Nestling recorded in Oct. No other information available.
Movements. Nothing recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Sulawesi EBA. Common and widespread in hill and, especially, montane forest in C Sulawesi; apparently uncommon on outlying ranges such as on N & E peninsulas; apparently absent from much of S peninsula S of Rantepao and Palopo. Old record from Sula Is (to which race *tonkeana* is geographically nearest) requires verification. Occurs in Lore Lindu National Park, in NC part of the island.
Bibliography. Andrew (1992), Andrew & Holmes (1990), Coates & Bishop (1997), Holmes & Phillipps (1996), Inskipp *et al.* (1996), Ripley (1941), Strange (2001), Stresemann (1940), Sujatnika *et al.* (1995), Voous & van Marle (1949), Watling (1983a), White & Bruce (1986).

14. Bar-bellied Cuckoo-shrike

Coracina striata

French: Échenilleur barré **German**: Bindenraupenfänger **Spanish**: Oruguero Barrado
Other common names: Barred Cuckoo-shrike

Taxonomy. *Corvus striatus* Boddaert, 1788, New Guinea; error = Luzon, Philippines.
Race *dobsoni*, considerably different from all others in plumage and proportions, also with different call, sometimes considered a full species; distinctive race *vordermani* may also merit elevation to species rank. Race *cebuensis* (from Cebu, in C Philippines) extinct. Fifteen extant subspecies recognized.
Subspecies and Distribution.
C. s. dobsoni (Ball, 1872) – Andaman Is.
C. s. sumatrensis (S. Müller, 1843) – extreme S Thailand, Peninsular Malaysia (including Tioman I), Sumatra (including Mentawai Is), Riau Archipelago, and Borneo and islands.
C. s. simalurensis (Richmond, 1903) – Simeulue I, off W Sumatra.
C. s. babiensis (Richmond, 1903) – Babi I, off W Sumatra.
C. s. kannegieteri (Büttikofer, 1896 – Nias I, off W Sumatra.
C. s. enganensis (Salvadori, 1892) – Enggano I, off W Sumatra.
C. s. bungurensis (Hartert, 1894) – Anamba Is and N Natuna Is.
C. s. vordermani (Hartert, 1901) – Kangean Is.
C. s. striata (Boddaert, 1783) – N Philippines (Luzon, Polillo, Lubang, Marinduque, Catanduanes).
C. s. difficilis (Hartert, 1895) – W Philippines (Busuanga, Culion, Palawan and Balabac).
C. s. mindorensis (Steere, 1890) – WC Philippines (Mindoro, Libagao, Tablas).
C. s. panayensis (Steere, 1890) – C Philippines (Ticao, Masbate, Panay, Guimaras, Negros).
C. s. boholensis Rand & Rabor, 1959 – EC Philippines (Samar, Calicoan, Biliran, Leyte, Bohol, Panaon).
C. s. kochii (Kutter, 1882) – S Philippines (Nipa, Mindanao, Malamaui, Basilan).
C. s. guillemardi (Salvadori, 1886) – Sula Archipelago (Jolo, Lapac, Tawi-Tawi, Sanga Sanga, Bongao, Simunul, Sibutu).

Descriptive notes. 24–32 cm; 98–128 g. Male nominate race is entirely dark plumbeous grey except for black lores and eyering, and largely black wings and tail; underparts, especially from belly to undertail-coverts, slightly paler than upperparts; iris dark brownish-red to straw-yellow; bill and legs black. Female is dark ashy grey above, lower back to uppertail-coverts barred black and white, lores and side of face dusky; lesser and median upperwing-coverts slightly darker than back, greater coverts ashy grey, remiges black, edged ashy grey, tertials almost entirely ashy grey, tail black; chin to breast ashy grey, rest of underparts, including axillaries and underwing-coverts, barred black and white, thighs dark ashy grey. Juvenile is finely barred black, grey and buff, remiges and rectrices strongly edged buff-white, lower belly to undertail-coverts white, eye brownish-white; immature like adult female, but barring more distinct and extending to breast, young male more leaden grey on upperparts and upper breast. Races differ mainly in size, colour, and/or extent of barring on rump and underparts: *dobsoni* is small, dark, male with bold barring on abdomen, crimson eye; *sumatrensis* male has some bars on rump and uppertail-coverts, indistinct bars on vent, whitish eye; *simalurensis*, *babiensis* and *enganensis* are unbarred in both sexes; *kannegieteri*, *bungurensis* and *difficilis* have unbarred males and barred females; *vordermani* male has barred undertail-coverts, female has unbarred whitish undertail-coverts; *mindorensis* is uniformly grey, female with trace of barring on underwing-coverts; *guillemardi* is similar to previous, but larger; *panayensis* is large, both sexes ventrally barred; *kochii* is smaller than previous, both sexes with less heavy barring on rump and abdomen and less black on lores; *boholensis* differs from last in having more and heavier barring on abdomen and undertail-coverts. Voice. Noisy; has loud, harsh "klee kleep" of 2–4 notes, usually given in flight (Philippines); clear whinnying "kliu-kliu-kliu" or shrill "kriiu-kriiu", and sharp, rising "see-up" (*sumatrensis*); very loud, piercing shrieking call in Andamans (*dobsoni*).
Habitat. Forest, freshwater swamp-forest, secondary growth and scrub; also mangrove forest; occasionally in old rubber and coconut plantations. Occupies mature forest regenerating after disturbance, including from logging. Lowlands to 900 m; to 2000 m in Philippines.
Food and Feeding. Eats adult and larval insects, including mantids (Mantidae), dragonflies (Odonata), beetles (Coleoptera) and lepidopterans; also takes large fruit of the fig *Ficus pisocarpa*. Large hairy caterpillars rubbed against a perch before being eaten; large figs held under a foot and picked apart. Forages in small groups, or in mixed-species flocks, especially with other cuckoo-shrikes and *Lalage* species, from canopy to middle stratum and at edges.
Breeding. Recorded in Apr–May, and dependent fledglings late Aug, in Malaysia; Feb in Sumatra; Apr–May in Philippines. Nest a shallow cup of mosses, small leaves, lichens and rootlets, placed up to 21 m above ground on forked branch of tree. Eggs 2; large chicks fed only by female. No other information.

On following pages: 15. Pied Cuckoo-shrike (*Coracina bicolor*); 16. Barred Cuckoo-shrike (*Coracina lineata*); 17. Boyer's Cuckoo-shrike (*Coracina boyeri*); 18. White-rumped Cuckoo-shrike (*Coracina leucopygia*).

Movements. None recorded.
Status and Conservation. Not globally threatened. Fairly common to uncommon or rare. Numbers probably reduced throughout its range by destruction of lowland forest. Apparently common in Philippines; race *cebuensis* believed extinct on Cebu since at least 1959, as a result of deforestation. Not uncommon in Kangean Is (*vordermani*). Race *sumatrensis* rare to locally fairly common in S Thailand and Peninsular Malaysia, where formerly locally commoner near coasts; no longer occurs in Singapore following destruction of mangrove-forest habitat; probably scarce in Sumatra. This race regarded as "Vulnerable" as a result of habitat destruction; although able to breed in secondary vegetation and isolated trees, it never occurs far from tall forest, with no confirmed occurrence significantly above the steepland boundary; occurs in Taman Negara National Park, in Peninsular Malaysia.

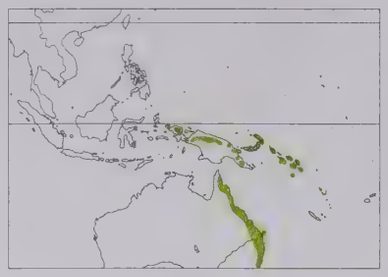
15. **Pied Cuckoo-shrike**

Coracina bicolor

French: Échenilleur bicolore **German**: Zweifarben-Raupenfänger **Spanish**: Oruguero Bicolor
Other common names: Muna/Bicoloured Cuckoo-shrike

Taxonomy. *Ceblepyris bicolor* Temminck, 1824, Sumatra; error = north Sulawesi.
Monotypic.
Distribution. Sulawesi (mainly in N) and adjacent islands (including Bangka, Manterawu, Togian Is, Muna, Buton), also Talaud Is and Sangihe Is.



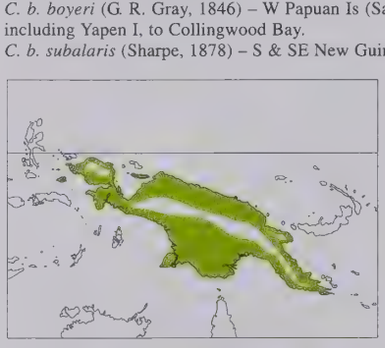
Descriptive notes. 31 cm. Male has top of head, upperparts and entire upperwings black, slightly glossed steel-green, lower back, rump and uppertail-coverts white; tail black, outer feathers tipped white; black of head extends down to lores, below eye and ear-coverts, the last two regions being spotted white; cheeks and entire underparts pure white, underwing-coverts and axillaries white; sometimes a trace of dark barring on rump, cheeks and underparts; iris dark brown; bill grey-blue; legs black. Distinguished from all congeners by combination of black upperparts, white rump and white underparts. Female is grey, not black, on upperparts, with throat and breast grey. Juvenile is like female, but has head and upperparts browner, with white feather edges; immature has grey upperparts, secondaries broadly edged white, rectrices tipped white. Voice. Song a loud, ringing series comprising 3–5 trisyllabic notes followed by 4–8 louder single whistles, this often preceded by several rasping notes.
Habitat. Primary lowland and hill forest, including forest edges and forest with clearings; also scrub and mangroves. To 500 m, sometimes to 900 m.
Food and Feeding. Food not recorded; presumably insects and fruit. Found in parties of 2–5 individuals; frequents the canopy.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Sulawesi EBA and Sangihe and Talaud EBA. Generally uncommon to rare on Sulawesi, and apparently absent from large parts of C & E regions, but locally common in N; uncommon on Buton. Only two records from Sangihe. Range apparently fragmented; forest destruction within the altitudinal range occupied by this species has been extensive in recent decades, and its populations must have suffered a decline. Occurs in Dumoga-Bone National Park, in Sulawesi.
Bibliography. Andrew (1992), Baltzer (1990), Catterall (1997), Coates & Bishop (1997), Collar & Andrew (1988), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Collar, Mallari & Tabaranza (1999), Holmes & Phillipps (1996), Inskipp *et al.* (1996), Riley (1997a), Ripley (1941), Sampiri (1996), Stattersfield & Capper (2000), Stresemann (1940), Sujatnika *et al.* (1995), Voous & van Marle (1949), Wardill (1995), Watling (1983a), White & Bruce (1986).

16. **Barred Cuckoo-shrike**

Coracina lineata

French: Échenilleur linéolé **German**: Gelbaugen-Raupenfänger **Spanish**: Oruguero Lineado
Other common names: Lineated/Yellow-eyed Cuckoo-shrike/Greybird

Taxonomy. *Ceblepyris lineata* Swainson, 1825, Moreton Bay, Queensland, Australia.
Ten subspecies recognized.
Subspecies and Distribution.
C. l. axillaris (Salvadori, 1876) – W Papuan Is (Waigeo I) and mountains of W, N & SE New Guinea (Vogelkop, N coastal ranges and Huon Peninsula).
C. l. maforensis (A. B. Meyer, 1874) – Numfoor I, in Geelvink Bay (NW New Guinea).
C. l. sublineata (P. L. Sclater, 1879) – Bismarck Archipelago (New Ireland, New Britain).
C. l. nigrifrons (Tristram, 1892) – N Solomon Is (Bougainville, Choiseul, Santa Isabel).
C. l. ombriosa (Rothschild & Hartert, 1905) – C Solomons (Kolombangara, New Georgia, Rendova and others).
C. l. pusilla (E. P. Ramsay, 1879) – Guadalcanal (S Solomons).
C. l. malaitae Mayr, 1931 – Malaita (S Solomons).
C. l. makirae Mayr, 1935 – San Cristobal (SE Solomons).
C. l. gracilis Mayr, 1931 – Rennell (extreme S Solomons).
C. l. lineata (Swainson, 1825) – NE Australia, from E Queensland S to NE New South Wales.
Descriptive notes. 22–29 cm; 66–100 g. Male nominate race has head, upperparts and upperwing-coverts uniformly dark blue-grey, narrow black line from lores to eye; greater upperwing-coverts edged white; alula, primary coverts and remiges black, edged whitish; rectrices mid-grey, becoming black distally; chin to breast as upperparts; lower breast to undertail-coverts, and axillaries and



underwing-coverts, barred white and black; iris pale yellow; bill and legs black. Easily distinguished from most congeners by pale yellow eyes and uniform grey upperparts. Female is like male, but lores grey. Juvenile has white areas of underparts tinged yellow; immature similar to adult female, but not properly described. Races differ mainly in size, and in extent of barring below: *axillaris* male has unbarred grey underparts, but female heavily barred below; *maforensis* is similar to previous, but male has fine white bars on breast; *sublineata* is also similar, but male has variable barring on belly, flanks and undertail-coverts; *nigrifrons* male is all light grey, female with abdomen extensively grey and with black bars very narrow; *ombriosa* female has blackest bars below; *pusilla* is very like previous; *malaitae* female has very narrow black bars on belly; *makirae* male has grey underparts with some barring; *gracilis* lacks sexual dimorphism, like nominate but much smaller. Voice. Pleasant chatter, "aw-loo-ack, aw-loo-ack, aw-lack, aw-lack", with tone of toy mouth organ, often given in flight; also repetitive "chirp". In New Guinea also a plaintive, downslurred whistling "whee" or "whee-uuu", often as a duet or in flight, and cat-like notes similar to those of *C. caerulogrisea*; pleasant "trill-yew" on Bougainville.
Habitat. Tropical and subtropical rainforest, eucalypt (*Eucalyptus*) forest, forest edge and secondary growth; also woodland, swamp-woodland, scrub plantations and gardens; often associated with native fig trees (*Ficus*). For breeding prefers woodland and open forest, rather than rainforest. In New Guinea, occurs at 600–1450 m; from sea-level to lower mountains in Bismarck Archipelago and Solomons.
Food and Feeding. Eats mainly fruit, especially *Ficus* but also *Calamus*, *Terminalia* and *Alphitonia*; also some insects, including lepidopteran larvae, dragonflies (Odonata) and beetles (Coleoptera). Forages actively among canopy foliage, in small parties, frequently moving from tree to tree; often associates with other fruit-eating birds. Congregates in parties of up to 50 individuals in non-breeding season.
Breeding. Breeds Oct–Feb in Australia and Oct and Dec in New Guinea; Aug on Bougainville. Both sexes collect nesting material, only one partner may build; nest a shallow saucer of fine twigs, casuarina (*Casuarina*) needles and leaves, bound with cobwebs, decorated with green moss, lichen and bark chips, placed up to 20 m above ground on horizontal or slightly sloping fork of tree branch. Eggs 1–2; both parents incubate, and both also care for nestlings; no information on incubation and fledging periods.
Movements. In Australia, nominate race present throughout year in some areas; in others considered locally nomadic, moving in search of fruit, and at R Murray small parties move S in spring. Lack of records from Torres Strait suggests regular migration unlikely, although there are records of nominate race from lowland New Guinea in Apr and Aug.
Status and Conservation. Not globally threatened. Status in Australia not clear; further fieldwork required. Locally fairly common in Papua New Guinea; widespread and common in the Solomons.
Bibliography. Beehler *et al.* (1986), Beruldsen (1980), Blaber (1990), Blakers *et al.* (1984), Christidis & Boles (1994), Clancy (1989, 1990), Coates (1990, 2001), Doughty *et al.* (1999), Galbraith & Galbraith (1962), Hall (1974), Higgins *et al.* (2005), Keast (1958), Leonard, J. (1998), Mayr (1955), Mayr & Rand (1937), Panetta (1980), Pizzey (1980), Rand & Gilliard (1967), Ripley (1941), Schodde & Mason (1999), Secomb (1992), Sibley (1951), Voous & van Marle (1949), Webb (1992).

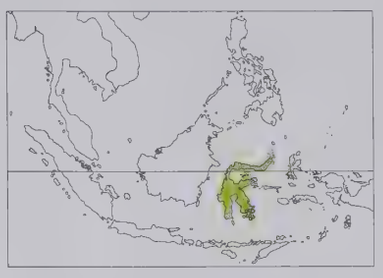
17. **Boyer's Cuckoo-shrike**

Coracina boyeri

French: Échenilleur de Boyer **German**: Rostachsel-Raupenfänger **Spanish**: Oruguero de Boyer
Other common names: Rufous-underwing/White-lored Cuckoo-shrike

Taxonomy. *Campephaga Boyeri* G. R. Gray, 1846, Triton Bay, New Guinea.
Two subspecies recognized.
Subspecies and Distribution.
C. b. boyeri (G. R. Gray, 1846) – W Papuan Is (Salawati, Misool), and NW & N New Guinea E, including Yapen I, to Collingwood Bay.
C. b. subalaris (Sharpe, 1878) – S & SE New Guinea (E to Milne Bay).

Descriptive notes. 22 cm; 61–74 g. Male nominate race has crown, nape, side of face and neck bright blue-grey, lores to eye, chin and upper throat black; upperparts and lesser upperwing-coverts duller greyish-blue; rest of upperwing-coverts ashy, edged greyish-blue; alula, primary coverts and primaries black, edged greyish-blue, secondaries and tertials black, broadly edged grey; rectrices black, central pair grey; underparts greyish-blue, underwing-coverts and axillaries orange-chestnut; iris dark brown; bill and legs black. Distinguished from most congeners by small size, pale blue-grey head contrasting with darker grey upperparts, cinnamon underwing-coverts; from *C. caeruleogrisea*, which also has rufous underwings, by much smaller size, shorter and less heavy bill. Female lacks black on head and has whitish lores. Juvenile is like female, but crown, upperparts and underparts mottled white and brown, remiges tipped whitish (tertials also edged whitish), eye deep brown, bill dark grey-brown, legs dark grey; immature also like female, young male lacking black on head, secondaries edged whitish, outer tail feathers tipped white. Race *subalaris* is more extensively black on throat and more orange-buff on underwing-coverts and axillaries than nominate, female with grey lores. Voice. Two or three hard notes followed by sweet, downslurred whistle, "tuk-tuk see-yu", apparently a duet, with short notes given by female and whistle by male; also repeated upslurred whistle, "sweei", clucking, chipping or ticking notes, cat-like mew and a repeated chirruping "chuck". Birds in Wau area have a duet, one bird giving a "weeowee" and the other a "wurr".
Habitat. Forest, forest edge, tall secondary growth, partly cleared areas and, locally, mangrove forest. Mainly in lowlands and hills, from sea-level to 1100 m, rarely to 1450 m.
Food and Feeding. Eats mainly fruit, especially figs (*Ficus*), but also takes insects. Moves in small parties, flying between trees with bouncing flight; rarely joins mixed-species bird parties. Forages mainly in upper canopy, sometimes descending to low secondary growth at forest edges. Gleans insects from bark and crevices while perched and while hovering under boughs.



Breeding. Recorded in Oct; recently fledged young recorded in Dec–Jan indicate breeding in period from late dry season to early wet season. One nest was of typical cuckoo-shrike structure, built on horizontal fork of a limb 30 m above ground; both parents fed the nestlings. No other information available.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Very common; the commonest forest cuckoo-shrike in New Guinea. Estimated density in lowland rainforest 10 birds/10 ha.
Bibliography. Andrew (1992), Beehler (1978a), Beehler *et al.* (1986), Bell (1982a, 1982b), Coates (1990, 2001), Diamond (1972, 1987), Gregory (1995), Mack *et al.* (2000), Mayr & Rand (1937), Mees (1965), Rand (1942), Rand & Gilliard (1967), Ripley (1941, 1964), Schmid (1993), Voous & van Marle (1949).

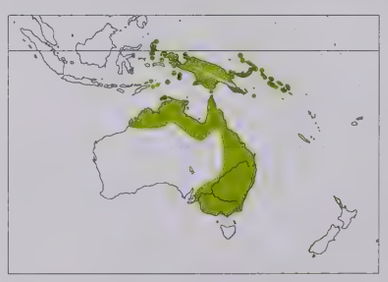
18. **White-rumped Cuckoo-shrike**

Coracina leucopygia

French: Échenilleur à croupion blanc **Spanish**: Oruguero Culiblanco
German: Weißbürzel-Raupenfänger
Other common names: Muna/Sulawesi Cuckoo-shrike

Taxonomy. *Graucalus leucopygius* Bonaparte, 1850, northern Sulawesi.
Forms a superspecies with *C. papuensis* and *C. ingens*. Monotypic.
Distribution. Sulawesi, including smaller islands of Manterawu, Manadotua, Talisei, Bangka, Lembeh, Togian, Tobea, Muna and Buton.
Descriptive notes. 29 cm. Male has dark ashy-grey head and upperparts, white lower rump and uppertail-coverts; forehead, lores, feathers around eye, upper ear-coverts and chin black; scapulars and lesser upperwing-coverts dark ashy grey, rest of upperwing-coverts, alula and remiges blackish, margined ashy grey; rectrices black, tipped grey on outer feathers; throat, breast and thighs

dark ashy grey, becoming white on lower flanks, belly and undertail-coverts; underwing-coverts white; iris yellow or creamy; bill and legs black. Differs from *C. papuensis* in darker grey plumage, blackish central tail feathers, yellow eye. Female is lighter grey than male, has no black on lores and side of face. Juvenile not properly described, but secondaries broadly edged and tipped white, primaries more narrowly so, tail feathers conspicuously tipped white; immature paler than adult, lacks black mask, has light grey face, upperparts, throat and breast, dusky grey barring on breast, with remiges and rectrices as juvenile. VOICE. Call a series of weak, nasal, squabbling/chattering notes, also described as a harsh staccato screech, rather resembles that of *C. papuensis*.
Habitat. Open wooded areas, lightly wooded cultivation, secondary woodland, scrub with trees, and swamp-forest. Sea-level to 800 m, locally to 1100 m in upland valleys.
Food and Feeding. Eats insects. Forages in canopy, sometimes on the ground, rarely in the middle storey.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Widespread and common on Sulawesi. Lives in close proximity to human settlements.
Bibliography. Andrew (1992), Baltzer (1990), Catterall (1997), Coates & Bishop (1997), Holmes & Phillipps (1996), Inskipp *et al.* (1996), Ripley (1941), Stresemann (1940), Voous & van Marle (1949), Watling (1983a), White & Bruce (1986).



19. White-bellied Cuckoo-shrike

Coracina papuensis

French: Échenilleur choucari **German**: Weißbauch-Raupenfänger **Spanish**: Oruguero Papúa
Other common names: Papuan Cuckoo-shrike (N & E races); White-bellied/White-breasted(!) Cuckoo-shrike/Greybird (*hypoleuca*); Little/Robust Cuckoo-shrike (*robusta*)

Taxonomy. *Corvus papuensis* J. F. Gmelin, 1788, Manokwari, Cendrawasi, north-west New Guinea.
Forms a superspecies with *C. leucopygia* and *C. ingens*. Until recently, the latter form was normally regarded as a race of present species, but it differs notably in large size, stout bill and more slaty coloration, and is probably more appropriately treated as a distinct species. Race *robusta* formerly treated as a full species, but now considered to fall within variation of present species. Birds ascribed to race *timorlaoensis* (of Tanimbar Is) may be nomadic vagrants from Australia. Birds from N Moluccas sometimes separated as race *melanolora*, but considered not satisfactorily distinguishable from nominate, with which merged. Australian races intergrade; proposed race *stalkeri* (E Australia) invalid, as refers to intergradient population in N & C Queensland, and therefore included in *oriomo*. Fourteen subspecies currently recognized.
Subspecies and Distribution.
C. p. papuensis (J. F. Gmelin, 1788) – N Moluccas (Morotai and Halmahera S to Obi), W Papuan Is (Waigeo, Salawati, Misool, Batanta), W & N New Guinea (including Yapen I), Lesser Sundas (Kisar, Luang, Sermata) and Kai Is.
C. p. timorlaoensis A. B. Meyer, 1884 – Tanimbar Is.
C. p. angustifrons (Sharpe, 1878) – C to SE New Guinea.
C. p. intermedia Rothschild, 1931 – SC New Guinea.
C. p. louisiadensis (Hartert, 1898) – Louisiade Archipelago.
C. p. oriomo Mayr & Rand, 1936 – S New Guinea (Trans-Fly region), islands in Torres Strait and NE Australia (Cape York Peninsula).
C. p. apsleyi Mathews, 1912 – coastal N Australia (Melville I, Cobourg Peninsula and shores of Van Diemen Gulf).
C. p. hypoleuca (Gould, 1848) – coastal N Australia (Kimberley E to Gulf of Carpentaria); non-breeding (probably this race) also in Kai Is and Aru Is.
C. p. artamoides Schodde & Mason, 1999 – E Australia (NE Queensland S to NE New South Wales).
C. p. robusta (Latham, 1801) – coastal SE Australia; non-breeding N to New South Wales and S Queensland.
C. p sclaterii (Salvadori, 1878) – Bismarck Archipelago.
C. p. perpallida Rothschild & Hartert, 1916 – N Solomon Is (Bougainville, Choiseul, Santa Isabel, Florida).
C. p. elegans (E. P. Ramsay, 1881) – C & S Solomons (New Georgia Is S to Guadalcanal).
C. p. eyerdami Mayr, 1931 – Malaita I (SE Solomons).

Descriptive notes. 22–29 cm; 55–80 g. Male nominate race has head, upperparts and upperwing-coverts pale grey, paler on rump and uppertail-coverts; black from lores to just behind eye, and narrow black frontal band; greater wing-coverts edged paler grey; alula and primary coverts black, margined white; primaries black with ashy-grey margins, secondaries largely grey on outer webs; slightly notched tail black, tipped pale grey, central two feathers grey; chin white; underparts pale grey, becoming white on belly and undertail-coverts; underwing-coverts and axillaries white; some individual variation in colour tones of plumage; iris very dark brown to black; bill black; legs grey to black. Separated from congeners by combination of pale grey plumage, whitish throat, breast and belly, and small black mask; from very immature *C. novaehollandiae* by smaller size, plain grey throat and breast, no black on ear-coverts. Female has duller, more sooty-black mask. Juvenile has grey (not black) mask, brown and whitish mottling on upperparts and breast; immature paler grey above than adult, underparts white except for grey breast, secondaries white on outer webs. Morphological differences between races complex, based on colour tone of head and upperparts, primary edges and underparts, darkness and extent of facial mask, presence or absence of faint grey ventral barring on female (and of ventral barring in immature), and size (including relative length of tail): *angustifrons* has upperparts much paler than nominate, primaries edged white; *intermedia* has upperparts intermediate in colour between previous and nominate; *oriomo* has head pale grey to mid-grey, less black on face than

nominate, white below but with greyish wash from breast to upper abdomen, light ventral barring; *hypoleuca* is larger than previous, head pale grey, breast white, female with reduced dark mask; *apsleyi* is similar to last but smaller, head pale grey to mid-grey, no ventral barring; *louisiadensis* is also similar, but wing shorter, bill longer; *robusta* is large, has head and upperparts grey, underparts pale grey to whitish (sometimes barred black on breast), rare dark morph has entirely black head, throat and breast (irregular blackish bars on lower breast) shading to dark grey on rest of upperparts and to pale grey on belly; *artamoides* resembles previous, but wing and tail smaller, head dark grey, light ventral barring, no dark morph; *perpallida* is small, pale overall; *elegans* is very like previous; *eyerdami* is also small, but slightly bigger and slightly darker than last two. Voice. Weak, squealing, slurred repeated "whee-eeyu" or "wee-yeer", rather like call of a parrot (Psittacidae), and a longer jumble of notes suggestive of sound of wind chimes; also has peevish "kisseek" or "ker-serk" call.

Habitat. Inhabits many vegetation types, including woodland, savanna, eucalypt (*Eucalyptus*) forest, riparian forest, rainforest, littoral forest, forest edges, secondary growth, mangroves, coconut, teak (*Tectona*) and *Araucaria* pine plantations, wooded farmlands and suburban gardens. Mainly in lowlands to 800 m, but recorded to 1650 m in New Guinea.

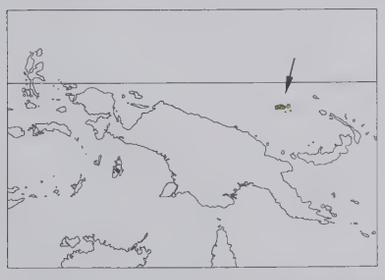
Food and Feeding. Eats mainly larger insects, including dragonflies (Odonata), cockroaches (Blattodea), mantids (Mantodea), grasshoppers (Orthoptera), bugs (Hemiptera), beetles (Coleoptera), stick-insects (Phasmatidae), lepidopteran larvae, and ants and wasps (Hymenoptera); spiders (Araneae) also recorded in diet. Also known to take fruit and seeds of plants such as *Ficus*, *Acacia*, *Cassia*, *Enchylaena* and grasses, and occasionally nectar. Usually forages singly, in twos or in small groups; moves slowly through trees from canopy to middle levels. Gleans insects from tree foliage, and also catches prey by sallying and flutter-chasing; occasionally hovers; sometimes forages on ground.

Breeding. Recorded in all months except Jul, in Australia; Aug, Oct, Dec–Jan and Mar–Jun in S New Guinea (Port Moresby region). Nest built by both adults, a small, shallow cup of fine twigs, bark, grass, leaves and vine tendrils, bound with spider webs, decorated with lichen, placed up to 7–10 m above ground on horizontal fork of tree branch. Eggs 1–3; both parents incubate the eggs and care for the nestlings; incubation period 21–22 days, fledging period 22 days. Nest success 52·9%.

Movements. Mainly resident or sedentary. Locally nomadic in Australia during dry winter season, when uncommonly found on islands in Torres Strait. Considered a non-breeding visitor in some parts of N, and race *robusta* probably a spring–summer visitor to SE South Australia; in Queensland, said to move N and towards coast in autumn; mainly a spring–summer visitor to Victoria. Possible passage recorded Australian mainland Mar–May and Sept–Dec. Birds identical with *hypoleuca* of N Australia observed in Kai Is and Aru Is in May, Jun, Nov and Dec. Other movements in Australia are not regular or not on large scale.

Status and Conservation. Not globally threatened. In Australia locally common to rare, and abundant in urban areas of tropics; generally common to very common in New Guinea; common and widespread in Solomon Is, and moderately common to common in N Moluccas; apparently uncommon to rare in E Wallacea. Recorded densities 0·01–1·76 birds/ha in Australia; in New Guinea, density in eucalypt woodland near Port Moresby was 0·08–0·19 birds/ha in 1982. In New Guinea increased greatly in abundance following clearing in Wau Valley, and has invaded other highland areas in disturbed habitats, but no similar increases have been noted in Australia.

Bibliography. Beehler (1978b), Beehler *et al.* (1986), Bell (1982a), Beruldsen (1980), Blakers *et al.* (1984), Christidis & Boles (1994), Coates (1990, 2001), Coates & Bishop (1997), Conole (1994), Doughty *et al.* (1999), Galbraith (1969), Galbraith & Galbraith (1962), Hall (1974), Hardy (1986), Higgins *et al.* (2005), Jaensch (1980, 1982), Keast (1958), Mack *et al.* (2000), Marchant (1989), Mayr (1955), Mayr & Rand (1937), Mees (1972, 1982), Pizzey (1980), Rand (1942), Rand & Gilliard (1967), Ripley (1941), Schodde & Mason (1999), Sibley (1951), Voous & van Marle (1949), White (1973), White & Bruce (1986).



20. Manus Cuckoo-shrike

Coracina ingens

French: Échenilleur de l'Amirauté **Spanish**: Oruguero de la Manus
German: Admiralitätsraupenfänger

Taxonomy. *Graucalus papuensis ingens* Rothschild and Hartert, 1914, Manus, Admiralty Islands.
Forms a superspecies with *C. leucopygia* and *C. papuensis*. Until recently, normally regarded as a race of latter, but differs notably in large size, stout bill and more slaty coloration, and probably more appropriately treated as a distinct species. Monotypic.

Distribution. Admiralty Is (Manus, Los Negros).

Descriptive notes. 28 cm. Male has head and neck medium grey, rest of upperparts and upperwing-coverts dingy slate-grey, paler on rump and uppertail-coverts; black from lores to behind eye, narrow black frontal band; greater wing-coverts edged pale grey; primary coverts black, margined white, alula and primaries black with ashy-grey margins, secondaries largely grey on outer webs; slightly notched tail black, tipped pale grey, central two feathers grey; underparts white, tinged dull ashy grey on throat and breast; underwing-coverts and axillaries white; iris dark brown; bill and legs black. Female has duller black mask. Immature and juvenile not described. Distinguished from similar *C. papuensis* by larger size and stouter bill (also much whiter below than Solomons races of latter); from other congeners by combination of grey upperparts, largely white underparts, small black mask. Voice. Common call "kitcheek" or "sh-zick".

Habitat. Forest edge, especially in tall isolated trees; rare in closed forest. Often around villages and in other disturbed habitats.

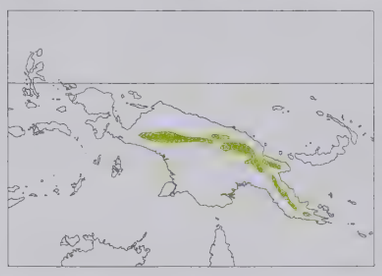
Food and Feeding. No information; probably similar to *C. papuensis*.

Breeding. No information.

Movements. None recorded.

Status and Conservation. Not globally threatened. Within context of very limited range, species is widespread, in small numbers, in suitable habitat. As this is a species of degraded habitats, it is unlikely to be at any immediate risk.

Bibliography. Buckingham *et al.* (1995), Coates (1990), Mayr (1955), Schodde & Mason (1999).



21. Hooded Cuckoo-shrike

Coracina longicauda

French: Échenilleur à longue queue **Spanish**: Oruguero Encapuchado
German: Langschwanz-Raupenfänger
Other common names: Black-hooded/Long-tailed Cuckoo-shrike

Taxonomy. *Graucalus longicauda* De Vis, 1890, Musgrave Range, 7000 to 9000 feet [c. 2130–2740 m], New Guinea.
Sometimes thought to form a species group with *C. larvata*, *C. temminckii* and *C. parvula*. Two subspecies recognized.

Subspecies and Distribution.
C. l. grisea Junge, 1939 – mountains of New Guinea from Snow Mts E to Huon Peninsula and Eastern Highlands Province.
C. l. longicauda (De Vis, 1890) – mountains of SE New Guinea.

Descriptive notes. 33 cm; 92–101 g. Distinctive, with grey and black plumage, very long tail. Male has head, neck, mantle, upper breast, alula, flight-feathers and tail black, head and neck with dark bluish sheen; rest of plumage soft grey, slightly paler on underparts and darker on underwing-coverts and undertail-coverts; iris dark brown to black; bill and legs black. Female is similar to male, but black on forepart of body restricted to "mask" from forehead to above eye, ear-coverts, malar region, chin and throat. Juvenile undescribed; immature similar to adult female. Races differ only in size: *grisea* is smaller than nominate. Voice. Vocal; common call a loud, descending squeal, "jeer-jeer-jeer", like that of a parrot (Psittacidae); also has a jangle of notes, harsh, rasping note ending sharply, plaintive trisyllabic "ti-ae-wi", and short, low-pitched chirp.

Habitat. Tall, dense montane forest, mainly between 2100 m and 2800 m; locally or occasionally as low as 1300 m and as high as 3700 m.

Food and Feeding. Eats mainly insects, including beetles (Coleoptera) and stick-insects (Phasmatidae); a little fruit also taken; small arboreal lizard recorded, and may also eat frogs. Forages in small groups, moving through treetops; hops slowly along branches when gleaning prey.

Breeding. Recorded in Jun and Oct. Nest a shallow cup of fine rootlets, with lichens on outside and small greenish leaves on inside, placed on foundation of moss on horizontal fork 15–20 m above ground. Eggs 1; both parents feed young. No other information.

Movements. None recorded.

Status and Conservation. Not globally threatened. Widespread; often scarce but locally fairly common in its restricted habitat.

Bibliography. Andrew (1992), Beehler (1978a), Beehler *et al.* (1986), Coates (1990), Diamond (1972), Gilliard & LeCroy (1961), Gregory (1995), Ingram (1960), Mayr & Rand (1937), Rand & Gilliard (1967), Ripley (1941, 1964), Voous & van Marle (1949).

22. Halmahera Cuckoo-shrike

Coracina parvula

French: Échenilleur d'Halmahera **Spanish**: Oruguero de Halmahera
German: Halmaheraraupenfänger

Taxonomy. *Graucalus parvulus* Salvadori, 1878, Halmahera.
Sometimes thought to form a species group with *C. larvata*, *C. temminckii* and *C. longicauda*; has been treated as a race of first-mentioned or of *C. personata*. Probably closest to *C. abbotti*. Monotypic.

Distribution. Halmahera, in N Moluccas.

Descriptive notes. 25 cm. Male is predominantly dark bluish-grey; glossy black on narrow forehead band, side of head, chin and throat; primaries black; central two rectrices dark bluish-grey, others black with grey at base, outermost with grey terminal spot; underwing-coverts white; iris apparently dark; bill black; legs dusky. Differs from *C. abbotti* in grey (not white) underparts, much larger size. Female undescribed. Juvenile and immature undescribed. Voice. A series of rapidly repeated staccato, chattering notes, slowing, descending and tailing off towards end.

Habitat. Primary forest and selectively logged hill forest, at 100–900 m.

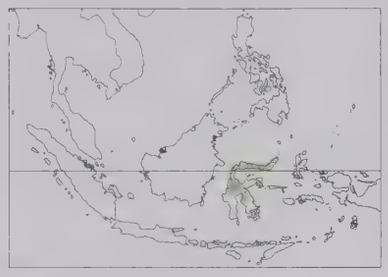
Food and Feeding. Food presumably insects. Frequents forest canopy and exposed perches in tops of dead trees, from which it sallies.

Breeding. No information.

Movements. No information.

Status and Conservation. Not globally threatened. Restricted-range species: present in Northern Maluku EBA. Extremely poorly known; appears to be local and uncommon in lowlands and more numerous above 700 m. Its numbers must have suffered from habitat destruction, but it does tolerate selectively logged forest.

Bibliography. Andrew (1992), Coates & Bishop (1997), Dickinson *et al.* (2002a), Inskipp *et al.* (1996), Lambert & Yong (1989), Michaux (1998), Ripley (1941), Strange (2001), Voous & van Marle (1949), White & Bruce (1986).



On following page: 23. Pygmy Cuckoo-shrike (*Coracina abbotti*); 24. New Caledonian Cuckoo-shrike (*Coracina analis*).

23. **Pygmy Cuckoo-shrike**

Coracina abbotti

French: Échenilleur d'Abbott **German**: Abbottraupenfänger **Spanish**: Oruguero de Abbott
Other common names: Celebes/(Celebes) Mountain Cuckoo-shrike

Taxonomy. *Celebesia abbotti* Riley, 1918, Rano-Rano, Sulawesi.
Sometimes included in genus *Edolisoma*. Probably closest to *C. parvula*. Monotypic.
Distribution. Mountains of N, NE, C & SW Sulawesi.

Descriptive notes. c. 20 cm. Male has upperparts dark bluish-grey; black on forehead, side of head, chin and throat; primaries black; secondaries, tertials and upperwing-coverts dark bluish-grey; central two rectrices dark bluish-grey, others black; underparts and underwing-coverts white; iris red; bill and legs black. Female has black of head and throat replaced by grey. Juvenile and immature undescribed. Differs from *C. parvula* in white (not blue-grey) underparts, smaller size. Voice. Usual call a thin, high-pitched, descending "thip"; song 2 quiet notes followed by a 4-note warble; sharp "tseet" calls in flight.
Habitat. Mountain forest at 1200–2500 m, mainly above 1400 m.
Food and Feeding. Insectivorous. Accompanies mixed-species parties. Gleans actively in canopy; apparently also behaves like a flycatcher (Muscicapidae), with aerial sallies.
Breeding. Juveniles in Nov, Dec and Mar. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Sulawesi EBA. Locally common to uncommon. No information on potential threats, but its numbers must have suffered from habitat destruction. Occurs in Lore Lindu National Park.
Bibliography. Andrew (1992), Andrew & Holmes (1990), Coates & Bishop (1997), Holmes & Phillipps (1996), Inskipp *et al.* (1996), Ripley (1941), Sujatnika *et al.* (1995), Voous & van Marle (1949), Watling (1983a), White & Bruce (1986).

24. **New Caledonian Cuckoo-shrike**

Coracina analis

French: Échenilleur de montagne **Spanish**: Oruguero de Nueva Caledonia
German: Rotsteiß-Raupenfänger
Other common names: New Caledonian Mountain Cuckoo-shrike

Taxonomy. *Campephaga analis* J. Verreaux and Des Murs, 1860, New Caledonia.
Monotypic.
Distribution. New Caledonia (Grande Terre and I des Pins).

Descriptive notes. 24-28 cm; male 97 g, female 70 g. Male is leaden grey above, somewhat paler grey below, with blackish alula and flight-feathers; underwing-coverts, bend of wing and undertail-coverts rufous-chestnut; iris orange-yellow to dark brown; bill blackish; legs blackish. Readily distinguished from other cuckoo-shrikes of the region by combination of grey plumage, chestnut undertail-coverts and deep yellow eye. Sexes alike, but female smaller than male. Juvenile is rather distinctive: has brownish wings, and is variegated rufous-white and blackish below; immature undescribed. Voice. Shrill whistles and a "tu-whit tu-whee" call note.
Habitat. Dense primary forest on mountains, above 200 m.
Food and Feeding. No information.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in New Caledonia EBA. Considered to be fairly common. Present in Rivière Bleue Reserve. No significant threats documented.
Bibliography. Barré & Dutson (2000), Doughty *et al.* (1999), Michaux (1998), Vuilleumier & Gochfeld (1976).

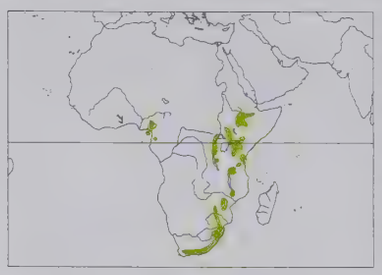
25. **White-breasted Cuckoo-shrike**

Coracina pectoralis

French: Échenilleur à ventre blanc **Spanish**: Oruguero Pechiblanco
German: Weißbrust-Raupenfänger
Other common names: Grey-throated/Black-chested Cuckoo-shrike

Taxonomy. *Graucalus pectoralis* Jardine and Selby, 1828, Sierra Leone.
Sometimes considered to form a superspecies with *C. caesia*, from which usually separated by altitude; the two are perhaps better treated as forming a species group, because plumages notably different. Monotypic.
Distribution. S Senegal S to Sierra Leone and E to W Sudan, Ethiopia, Uganda and W Kenya, and from S DRCongo, Rwanda, Burundi and W & S Tanzania S to Angola, N Namibia, N Botswana, Zimbabwe, Mozambique and extreme NE South Africa.



Descriptive notes. 25–27 cm; 49–58 g. Male has black preorbital region and white eyering; grey on head and upperparts and from chin to upper breast, paler on forehead and darker on throat and upper breast; alula, remiges and primary coverts black, edged grey; tail feathers blackish-brown, central pair grey; lower breast to undertail-coverts white, underwing-coverts and axillaries white; iris dark sepia; bill and legs black. Distinguished from *C. graueri* by larger size, paler head, upperparts and upper breast. Female is similar to male, but has chin and upper throat white, grading to pale grey on upper breast, sometimes faint grey bars on lower breast and flanks, also has less black on loral region. Juvenile has top of head to hindneck white with dark brown arrow-shaped marks, dark brown upperparts with white feather fringes and bases, white underparts spotted dark brown, remiges and upperwing-coverts edged white, wing-coverts with black band; immature not fully described. Voice. Fairly loud, long, high-pitched, rather buzzing downslurred whistle lasting 1–1·5 seconds; also a thin, high-pitched "seeeu" whistle, and other weak, high-pitched notes e.g. "tsip-tsip", "tsitsitsi" and "sweet-sweet"; in addition, makes a louder "wreewree-tiuptiup", a rolling repeated "wrrllu", and (male only) a soft whistled "duid-duid".
Habitat. N of equator occurs in mature savanna woodland and bushy savanna with open groves of tall trees, especially acacia (*Acacia*); in S inhabits tall, broadleaf woodland such as *Brachystegia*, *Baikiaea* and mopane (*Colophospermum mopane*). Normally below 1500 m. Where sympatric with *C. caesia*, present species occurs in lower-altitude woodland.
Food and Feeding. Insects, especially caterpillars (Lepidoptera), also orthopterans, hymenopterans (including ants), termites (Isoptera) and mantids (Mantidae). Forages mainly in canopy and upper regions of trees. Gleans trunks, branches and leaves; moves with long hops and pauses to inspect potential sites for prey; also hawks insects (including termite alates) in the air. Occasionally takes prey from the ground. Regularly joins mixed-species flocks.
Breeding. Breeds mainly from end of dry season and through rains; Jun in Gambia, Jan in Ghana, Sept in SE DRCongo, Oct–Feb and May in Malawi, Aug–Dec in Zambia and Zimbabwe, Aug–Sept in Angola, and Nov in South Africa; single-brooded. Monogamous; territorial. Nest usually built by female, but sometimes by male or by both sexes, built in c. 5–6 days; a shallow cup of weed stems, tendrils, leaf petioles or leaf veins, covered and lined with lichens, anchored with spider webs, situated 6–15 m above ground on tree branch, usually in a wide, flat fork. Eggs 1–2; incubation shared by both sexes, period 23 days; chicks fed by both parents, leaving nest at 24–30 days, but remaining dependent on parents for a further 2–3 months; juveniles stay with parents until following breeding season. In Zimbabwe, average success 42%, mean 0·8 fledglings produced per nesting attempt.
Movements. Largely resident; seasonal movements in some areas. In Sudan, some move N in rains; in Central African Republic apparently absent early in dry season (Oct–Jan); in S Africa some move to drier savanna after breeding, and also to lower elevations in Malawi, Zambia and Zimbabwe; occurs mainly in austral winter in N South Africa. Vagrant in Mauritania, SE Kenya, N Tanzania, NW Namibia and S Botswana.
Status and Conservation. Not globally threatened. Generally locally frequent to uncommon in N of range, but rare in Rwanda and Kenya; common in Angola; mainly uncommon S from Malawi and Zimbabwe, and rare in South Africa; local in Namibia and Botswana. Density in Zimbabwe estimated at 1 pair/20 ha. Numbers must be adversely affected by woodland clearance throughout its range; possibly threatened in some parts of Zimbabwe by fragmentation of miombo woodlands. Occurs in numerous protected areas throughout its sizeable range.
Bibliography. Anon. (1992, 2000b), Bannerman (1953), Barlow *et al.* (1997), Benson *et al.* (1971), Borrow & Demey (2001), Brooke (1984a), Brown (1993), Butchart (1997), Byaruhanga *et al.* (2001), Chapin (1953), Cheke & Walsh (1996), Cizek (2001), Dean (2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Forbes-Watson (1994), Ginn *et al.* (1989), Gore (1990), Grimes (1987), Hall & Moreau (1970), Harrison *et al.* (1997), Hustler & Prescott (1992), Irwin (1980, 1981), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993), Monadjem (1996), Nikolaus (1987), Penry (1994), Sinclair & Hockey (1996), Skinner (1995), Tarboton (2001), Vernon (1980, 1984), Vincent (1949), Whittingham (1964), Woodall (1971), Zimmerman *et al.* (1996).

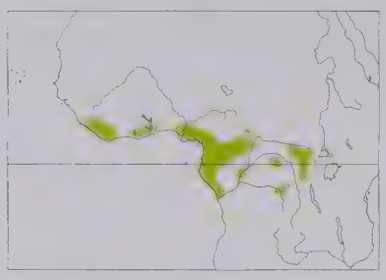
26. **Grey Cuckoo-shrike**

Coracina caesia

French: Échenilleur gris **German**: Waldraupenfänger **Spanish**: Oruguero Gris
Other common names: African Greybird

Taxonomy. *Ceblepyris caesia* M. H. K. Lichtenstein, 1823, Eastern Cape Province, South Africa.
Sometimes considered to form a superspecies with *C. pectoralis*, from which usually separated by altitude; the two are perhaps better treated as forming a species group, because plumages notably different. Proposed race *preussi* (E Nigeria and Bioko I), with slightly darker throat than *pura*, seems better merged with latter. Two subspecies currently recognized.
Subspecies and Distribution.
C. c. pura (Sharpe, 1891) – SE Nigeria (Obudu Plateau), W Cameroon and Equatorial Guinea (Bioko I and Mt Alen); also Ethiopia, SE Sudan, Uganda and NE DRCongo S to Malawi and adjacent NW Mozambique.
C. c. caesia (M. H. K. Lichtenstein, 1823) – Zimbabwe and Mozambique S to South Africa.

Descriptive notes. 25–27 cm; 53–66 g (nominate), 40–63 g (*pura*). Male is almost entirely uniform medium grey, paler on forehead and forecrown and around eye, with black preorbital region and white eyering; remiges, alula and primary coverts black with grey outer edges; rectrices blackish to blackish-grey, becoming paler towards tips; underwing-coverts and axillaries pale grey; iris dark brown to black; bill and legs black. Differs from *C. pectoralis* and *C. graueri* in having grey, not white, underparts. Female is paler than male, especially on chin and throat, with preorbital area grey. Juvenile is distinctive, dark brown with grey-white fringing and barring above, white with dark grey-brown bars below, with black tail tipped or edged white; immature not fully described. Race *pura* differs from nominate in smaller size. Voice. Thin, high-pitched, downslurred whistle, "seeea" or "peeee-oooo", lasting c. 0·5 seconds; also high-pitched trilling and chittering notes, a chattering like that of a weaver (*Ploceus*), sneeze-like "chi-oo", and quiet "tseeee" or "tsiptsip tswee" when foraging; wispy "swee" note at nest.
Habitat. Evergreen forest, forest patches, well-wooded watercourses with tall trees, and scattered trees between forest patches; occasionally in old pine (*Pinus*) and wattle (*Acacia*) plantations, and in suburban gardens (South Africa). In non-breeding season in South Africa, also in woodland, usually denser growth along drainage lines, and even in dense bush dominated by acacia (*Acacia*) with evergreen thickets. Typically at higher altitudes, above 1000 m in W Africa and 1500–3000 m in C & E Africa, but also down to 900 m or lower in E Tanzania, and exceptionally near sea-level in coastal Cameroon and Kenya; farther S occurs at lower elevations, mainly below 1200 m in Zimbabwe and to sea-level in South Africa. Found at higher altitudes than *C. pectoralis*, and also in forest (not woodland), where the two sympatric; generally at higher elevations than forest-dwelling *C. graueri*.
Food and Feeding. Takes insects, particularly caterpillars (Lepidoptera), crickets (Gryllidae) and grasshoppers (Orthoptera), as well as termite alates (Isoptera) and beetles (Coleoptera); also spiders (Araneae). Forages in canopy, catching insects by hawking from a perch or by hopping and picking up prey on trunks and branches; perches on branches and peers upwards at undersides of leaves, flying up to snatch prey thus seen and returning to perch to swallow it. Regularly joins mixed-species parties.
Breeding. Breeds during rains, but avoids wettest months: Aug and Dec in Sudan, possibly Feb–Mar in Ethiopia; Jan–Mar, Aug, Oct and Dec in Uganda, Kenya and Tanzania; Jan–Jun and Aug in DRCongo and Sept in Malawi; Nov–Dec in S, but nest-building recorded Sept in S South Africa; birds in breeding condition in Nov in Cameroon. Monogamous. Nest built by both sexes, a shallow bowl of *Usnea* lichens bound with spider webs, plastered on to sloping fork or on branch, fairly high (up to 20 m) in tree. Eggs 1–2; incubation by both sexes, period unknown; no information on fledging period; young remain with parents until following breeding season.
Movements. Largely resident, but some local seasonal movements. Some post-breeding migration to lower elevations in Cameroon. In South Africa, altitudinal migration in N (former Transvaal) from high forests to base of escarpments and lowvelds (non-breeding visitor Feb–Jul and Oct, and to bush at 800 m in Pietermaritzburg (KwaZulu-Natal) and E Cape coast; non-breeding visitor and vagrant (occasional breeding attempts) in SW Cape. Also some movements in Zimbabwe, where one found at Emberengwa Mt (300 km W of normal range), and in Kenya (one on coast, 100 km NE of Usambaras, in Mar). Vagrant in Central African Republic (Manovo–Gounda–Saint Floris National Park).
Status and Conservation. Not globally threatened. Locally frequent to common in N of range, but rare on Bioko I; mainly uncommon S from Malawi and Zimbabwe. Density in NE South Africa 6 birds/4·5 ha. May be threatened by forest clearance, although increases in secondary forest and forest-edge habitats may have been beneficial locally. Tolerates presence of humans and occurs in town and garden trees. Occurs in a number of national parks and other protected areas.
Bibliography. Bannerman (1953), Bennun & Ngoroje (1999), Benson & Benson (1977), Berruti *et al.* (1994), Blake *et al.* (1990), Brown & Britton (1980), Burgess & Mlingwa (2000), Byaruhanga *et al.* (2001), Chapin (1953), Clancey (1964), Cordeiro (1994a), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fishpool & Evans (2001), Fotso (1996), Ginn *et al.* (1989), Hall & Moreau (1970), Harrison *et al.* (1997), Irwin (1981), Keith *et al.* (1992), Lewis & Pomeroy (1989), Macdonald (1984b), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993), Martin *et al.* (1979), McGill & Nixon (1991), Nikolaus (1987), Pickles (1989), Prigogine (1980b), Rodewald *et al.* (1994), Sinclair & Hockey (1996), Skead (1995), Steyn (1996), Stuart (1986), Symes *et al.* (2002), Tarboton (2001), Tarboton *et al.* (1987), Tye (1992), Vernon (1972a, 1980).



27. **Blue Cuckoo-shrike**

Coracina azurea

French: Échenilleur bleu **German**: Azurraupenfänger **Spanish**: Oruguero Azulado
Other common names: African Blue Cuckoo-shrike

Taxonomy. *Graucalus azureus* Cassin, 1852, Sierra Leone.
Sometimes thought to form a superspecies with *C. graueri*. Monotypic.
Distribution. Sierra Leone E, discontinuously, to S Ivory Coast, S Ghana and Togo, S Nigeria and SW Cameroon, S to Gabon, SW PRCongo (Mayombe) and adjacent NW Angola (Cabinda); also SW Central African Republic and N & C DRCongo.
Descriptive notes. 21 cm; 43–51 g. Distinctive. Male is entirely brilliant glossy blue, except for black forehead, preorbital region and band above eye, bluish-black chin, ultramarine throat, black rectrices (central pair edged blue), and black alula, primaries and secondaries (edged blue); iris brownish-red to dark crimson; bill and legs black. Female is similar to male, but greener, less brilliant blue, with throat as underparts. Juvenile is like female, but belly feathers edged white,

On following pages: 28. Grauer's Cuckoo-shrike (*Coracina graueri*); 29. Madagascar Cuckoo-shrike (*Coracina cinerea*); 30. Mauritius Cuckoo-shrike (*Coracina typica*); 31. Reunion Cuckoo-shrike (*Coracina newtoni*).

secondaries and primary coverts edged white and mottled blue-grey, tertials with distal black and white bars, tail tipped white, eye brownish-red; immature not fully described. Voice. Relatively vocal. Calls include a hoarse, nasal "chwee-ep" or "chuee", short "chupr" and a series of "tuk" notes. Song in Gabon is a clear, powerful, downslurred "peeeoo" prefaced by a short "chup"; calls well spaced, and often punctuated by conversational "chup-puji" or "wee-chup" calls or by chattering "chachacha-chacha". Song in Ivory Coast more nasal, a mixture of upslurred and downslurred notes, e.g. "pooeet-pooit-pooeet-peeoo", interspersed with sharp fast chatter and nasal "wer-tit".

Habitat. Lowland primary forest and mature secondary forest; also open woodland and sometimes clearings; rarely descends to undergrowth and edges. In E DRCongo occurs below 1190 m, thus at lower elevations than those occupied by *C. graueri*.

Food and Feeding. Eats mainly caterpillars (Lepidoptera) and grasshoppers (Orthoptera); also termite alates (Isoptera), beetles (Coleoptera), snails (Gastropoda); occasionally fruit, such as *Croton*. Forages in foliage of upper canopy and treetops; sallies like a flycatcher (Muscicapidae), snatching prey in the air and from foliage; also gleans while running or hopping along branches and vines, and takes prey from undersides of leaves. Joins mixed-species bird parties, especially in dry season.

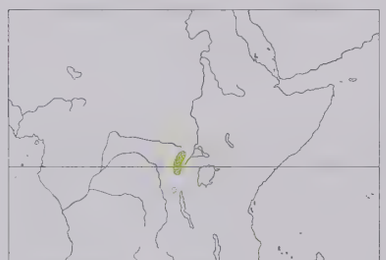
Breeding. Mainly Nov–Mar, when rainfall relatively low; breeding activity in Jan and Mar in Liberia, Feb and May in Ghana, Feb in Nigeria and Oct–Feb in Gabon; breeding condition in Sept in Angola. Monogamous; probably territorial. Nest a loose bowl of lichens and spider webs on horizontal tree branch. No other information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Rare to uncommon in some areas. Was locally frequent to common in some parts of range in 1980s, when estimated density in NE Gabon was 5–7 pairs/km². Known range fragmented. Has suffered considerably from habitat destruction. Occurs in some protected areas, including Taï Forest National Park, in Ivory Coast, and Korup National Park, in Cameroon.

Bibliography. Bannerman (1953), Borrow & Demey (2001), Brosset & Érard (1986), Butynski (1994), Carroll (1988), Chapin (1953), Cheke & Walsh (1996), Christy & Clarke (1994), Dean (2000), Demey & Fishpool (1991), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1991), Dowsett-Lemaire *et al.* (1993), Elgood *et al.* (1994), Fishpool & Evans (2001), Gee & Heigham (1977), Grimes (1987), Hall & Moreau (1970), Halleux (1994), Hopkins (1970), Keith *et al.* (1992), Mackenzie (1979), Mackworth-Praed & Grant (1973), Prigogine (1953, 1980b), Rodewald *et al.* (1994).

28. Grauer's Cuckoo-shrike



Coracina graueri

French: Échenilleur de Grauer **German**: Silberraupenfänger **Spanish**: Oruguero de Grauer

Taxonomy. *Coracina graueri* Newman, 1908, 90 km W of Lake Edward, DRCongo.

Sometimes thought to form a superspecies with *C. azurea*. Relatively fine bill and colour of upperparts suggest possible link with *C. cinerea* of Madagascar and with Asiatic group comprising *C. melaschistos*, *C. fimbriata* and *C. melanoptera*. Monotypic.

Distribution. E DRCongo.

Descriptive notes. c. 22 cm. Grey and white cuckoo-shrike with relatively fine bill. Male has entire head, upperparts and breast dark slate-grey, blacker on lores, around eye and from chin to breast; slight greenish-blue gloss on upperparts, side of neck and breast; wings dark slate-grey, glossy blue-green edges of secondaries, tertials and upperwing-coverts; alula and primaries black; tail black with bluish sheen, outer two feathers tipped white; underparts white, lower flanks and thighs medium grey; underwing-coverts and axillaries white; iris dark brown; bill black; legs blackish-grey. Differs from similar *C. pectoralis* by smaller size, darker grey head, upperparts and breast; from *C. caesia* by white underparts. Female is slightly paler above than male, medium grey on side of head and neck, and chin to upper breast, darker lores, and has pale buff undertail-coverts. Juvenile is like female, but forehead light grey, lores spotted black, throat grey with some blackish feathers, undertail-coverts beige; immature not fully described. Voice. Undescribed.

Habitat. Montane and transitional forest, at 1150–1900 m. Separated altitudinally from *C. azurea*, which occurs at lower elevations (below 1190 m); typically at lower elevations than *C. caesia*.

Food and Feeding. Feeds mainly on caterpillars (including hairy ones). Foraging in canopy and middle levels, also in understorey.

Breeding. Laying dates Jan, May and Jun, at end of rains. No other information.

Movements. Apparently sedentary.

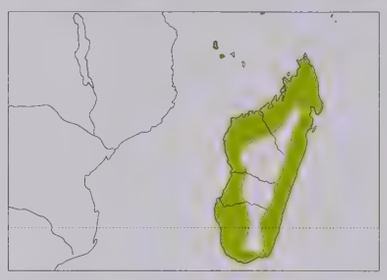
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Albertine Rift Mountains EBA. Extremely local and uncommon within its small range. Found only in highlands along W side of Albertine Rift from Djugu and Mongbwalu (W of L Albert) S to Lutunguru (W of L Edward); also from Mt Kahuzi S to R Elila W of Uvira. Potentially threatened by forest clearance for slash-and-burn agriculture, and by unregulated logging.

Bibliography. Chapin (1953), Collar *et al.* (1994), Dowsett (1985a), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Hall & Moreau (1970), Keith *et al.* (1992), Lippens & Wille (1976), Mackworth-Praed & Grant (1973), Pedersen (2000), Prigogine (1953, 1980b), Sinclair & Ryan (2003), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Vande weghe (1992).

29. Madagascar Cuckoo-shrike

Coracina cinerea

French: Échenilleur malgache **Spanish**: Oruguero Malgache
German: Madagaskarraupenfänger



Other common names: Ashy Cuckoo-shrike; Comoro Cuckoo-shrike (*cucullata* and *moheliensis*)

Taxonomy. *Muscicapa cinerea* Statius Muller, 1776, Madagascar.

Relatively fine bill and colour of upperparts suggest possible link with *C. graueri* of E DRCongo and with Asiatic group comprising *C. melaschistos*, *C. fimbriata* and *C. melanoptera*. Races *cucullata* and *moheliensis* sometimes considered a separate species by virtue of differences in plumage, size and voice. Form described as *C. sulphurea* is a colour morph of *cucullata*. Four subspecies recognized.

Subspecies and Distribution.

C. c. cucullata (Milne-Edwards & Oustalet, 1885) – Grand Comoro (Njazidja), in Comoro Is.
C. c. moheliensis Benson, 1960 – Mohéli (Mwali), in Comoro Is.
C. c. cinerea (Statius Muller, 1776) – N & E Madagascar.
C. c. pallida Delacour, 1931 – W, C & SW Madagascar.

Descriptive notes. 22–24 cm; 41·5–45g (nominate). Male nominate race has entire head and neck black, upperparts, including upperwing-coverts and tertials, uniform dark grey; alula, primary coverts, primaries and secondaries black, edged grey; tail grey, outer feather pair blackish with white tips; underparts (including underwing) pale grey, lighter on breast; iris dark reddish-brown; bill and legs black. Readily distinguished from African congeners by combination of black hood, grey upperparts and pale grey (not white) underparts. Female has grey head and neck, and paler grey upperparts than male. Juvenile is similar to female, but upperwing-coverts edged buff; immature not fully described. Race *pallida* is paler overall than nominate, male also having grey hood separated by whitish area from pale grey underparts, and white undertail-coverts; *cucullata* is smaller, darker above, marginally paler on head, dark nuchal collar, almost white underparts, upper chest pure white, also occurs as olive morph having olive-green hood and upperparts and primrose-yellow underparts ("*sulphurea*"); *moheliensis* differs from previous mainly in having no contrast between crown and mantle, slightly stronger grey wash on underparts (including chest), also no olive morph. Voice. Distinctive song, often heard, a series of hard notes followed by fluted notes that decrease in volume, "kiap kiap kiap kiap cheeekeekeekee-kee-kee-kee-kee"; often repeated, and "kee" notes may be replaced by "kick-oo" notes. Race *cucullata* has softer "cheekee keedee" call.

Habitat. Lowland to mid-altitude humid evergreen forest, dry forest, gallery forest, forest edge, secondary growth, scrub and mangroves; sometimes adjacent degraded terrain; from sea-level up to 2300 m.

Food and Feeding. Eats variety of invertebrates, including beetles (Coleoptera), lepidopteran and other larvae, orthopterans, cicadas (Cicadidae), mantids (Mantidae), spiders (Arachnida), centipedes (Chilopoda), myriapods; fruit remains found in one stomach. Often accompanies mixed-species flocks. Usually forages in canopy, sometimes in middle levels, searching foliage and branches. Prey often struck against a perch before being swallowed.

Breeding. Nov–Mar. Nest shallow, bowl-shaped, largely of mosses and lichens, usually placed on horizontal branch high in tree. Lays 1 egg. No other information.

Movements. None recorded.

Status and Conservation. Not globally threatened. Common in suitable habitat in Madagascar; uncommon in Comoros. Presumably at some degree of risk as a result of forest destruction, but few data available.

Bibliography. Bangs (1918), Benson (1960, 1971b), Benson *et al.* (1976), Dee (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Eguchi *et al.* (1993), Fjeldså *et al.* (1999), Horne (1987), Langrand (1990, 1995), Louette (1988), Louette *et al.* (1988), Milon *et al.* (1973), Morris & Hawkins (1998), Safford & Duckworth (1990), Sinclair & Langrand (1998), Thompson *et al.* (1987), Yamagishi *et al.* (1997).

30. Mauritius Cuckoo-shrike

Coracina typica

French: Échenilleur de Maurice **Spanish**: Oruguero de Mauricio
German: Mauritiusraupenfänger

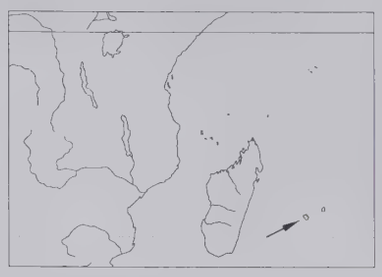
Taxonomy. *Oxynotus typicus* Hartlaub, 1865, Mauritius.

Sometimes placed in a separate genus *Coquus*. Forms a superspecies with *C. newtoni*. No other obviously close relatives; plumage similarities (including marked sexual dichromatism and sequence of immature plumages) with Australasian *C. tenuirostris*, *C. schisticeps* and *C. melas* may indicate either common ancestry or convergence. Monotypic.

Distribution. S Mauritius.

Descriptive notes. 22 cm; one male 43 g. Male has top and side of head slate-grey, upper lores and stripe over eye whitish, ear-coverts pale grey; upperparts, including lesser upperwing-coverts, slate-grey; rest of upperwing-coverts, and remiges, blackish, edged slate-grey, primaries and secondaries edged and tipped white; rectrices black, central pair edged grey, others tipped white; chin and throat white, underparts light grey, undertail-coverts white; underwing-coverts and axillaries white; iris hazel; bill and legs black. Distinguished from similar *C. newtoni* by darker upperparts. Female has olivaceous-brown head, whitish lores, rufous-mottled ear-coverts and white chin; dull rufous-brown upperparts, more brick-red on rump and uppertail-coverts, dull rufous-brown lesser coverts, rest of upperwing-coverts, and remiges, blackish-brown, edged reddish-brown, primaries tipped whitish; rectrices blackish, tipped pale reddish, central pair brown; underparts chestnut, paler on underwing-coverts. Juvenile has brown upperparts with buff and blackish crescentic markings, pinkish-white underparts with dark streaks; immature like adult female, young male having variable amount of white mixed with chestnut of underparts. Voice. Melodic series of short whistles preceded by few sharper, faster notes, female uttering fewer whistled notes than male; female has "buzz kek" contact call. Also has harsh "tschrek" call note, scolding "kek" and aggressive squeak.

Habitat. Canopy of moist tropical evergreen forest, also adjacent degraded or altered forest, and scrub; 200–800 m, mostly above 460 m.



Food and Feeding. Food mainly large arboreal arthropods, including mantids (Mantodea), stick-insects (Phasmatidae), bush-crickets (Tettigoniidae), beetles (Coleoptera), adult and larval lepidopterans, and spiders (Arachnida); also takes geckos (Gekkonidae). Jumps or flies between perches, searching trunks, branches, twigs and leaves; prey usually captured by gleaning, sometimes by "leap-snatching"; also catches prey in air by hovering or direct flight. Large prey beaten against branches. Sometimes joins mixed-species flocks.
Breeding. Breeds Sept–Mar, during rains. Monogamous; permanently territorial. Nest built by both sexes, a very shallow cup of fine twigs, lichens and spider webs, usually attached to horizontal fork of tree branch. Eggs 2–3; incubation by both sexes, period 24–25 days; chicks fed by both parents, fledging at 22–24 days; young may remain with parents for over 3 months. Nests often preyed on.
Movements. None recorded.
Status and Conservation. VULNERABLE. Restricted-range species: present in Mauritius EBA. Has very small range (c. 117 km², comprising four areas) and small population, estimated at 300–350 pairs in 2000. Highest recorded density 25 territories/km². Habitat loss and degradation have caused long-term population decline since human colonization of the island, and remain a threat. Introduced predators and, to lesser extent, cyclones, take a heavy toll on nests; introduced Common Myna (*Acridotheres tristis*) eats similar food and may be a competitor. Since 1975, this species' population, range and density have increased as a result of conservation action to rehabilitate native ecosystems, and it has colonized lowlands in two areas. It is intended to translocate pairs to new areas on Mauritius, and eventually also to adjacent islets after rehabilitation of islet ecosystems. Conservation status could be downlisted to that of Near-threatened if such action successful, although population would have to increase by 50–70%.
Bibliography. Benson (1971b), Cheke (1983, 1987a), Cheke & Jones (1987), Collar & Stuart (1985, 1988), Collar *et al.* (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Green & Hirons (1991), Horne (1987), King (1978/79), Lorence & Sussman (1986), McKelvey (1977), Meinertzhagen (1912), Pollen (1866), Procter & Salm (1974), Safford (1997, 2000), Safford & Beaumont (1996), Safford & Jones (1997, 1998), Sinclair & Langrand (1998), Stattersfield & Capper (2000), Temple (1974), Temple *et al.* (1974).

31. **Reunion Cuckoo-shrike**

Coracina newtoni

French: Échenilleur cuisenier **German**: Newtonraupenfänger **Spanish**: Oruguero de Reunión

Taxonomy. *Oxynotus newtoni* Pollen, 1866, Reunion Island.
Forms a superspecies with *C. typica*. No other obviously close relatives; plumage similarities (including marked sexual dichromatism) with Australasian *C. tenuirostris*, *C. schisticeps* and *C. melas* may indicate either common ancestry or convergence. Monotypic.
Distribution. NW Reunion I.
Descriptive notes. 22 cm. Male has ashy-grey upperparts, paler on rump and uppertail-coverts, blackish spot in front of eye, dull ashy-grey ear-coverts and face side spotted white below eye; upperwings black, narrow grey margins on wing-coverts, whitish edges and tips of primaries and secondaries; rectrices black, tipped white; chin and upper throat greyish-white, underparts pale grey, white on central belly, undertail-coverts and underwing-coverts; iris brown; bill and legs blackish or bluish. Distinguished from similar *C. typica* by paler grey upperparts. Female has very obvious narrow white eyebrow, dark rusty-brown upperparts, paler on head side, faintly barred dusky on rump and uppertail-coverts, dark brown upperwing-coverts (except lessers) and remiges

edged rusty brown (primaries edged whitish-brown); underparts whitish, finely barred dull blackish, breast and flanks washed fulvous. Juvenile is similar to female; immature not fully described, apparently similar to adult female. VOICE. Male has shrill, clear, repeated whistled, "tui", and harsh, scolding "kek", often repeated; female a harsh alarm note; both sexes also have aggressive squeak.
Habitat. Primarily canopy of closed montane moist forest, including steep, forested gulleys, and occurs also in areas of heath (*Philippa montana*) within forested areas and occasionally in Japanese red cedar (*Cryptomeria japonica*) plantations; 1150–1850 m. Formerly occurred down to 800 m, but forest at lower altitudes now lost.
Food and Feeding. Chiefly insectivorous; fruits of some native trees (*Aphloia*, *Ficus*) also taken. Eats adult and larval beetles (Coleoptera), especially longhorn beetles (Cerambycidae), also adult and larval lepidopterans, flies (Diptera), hymenopterans, orthopterans, stick-insects (Phasmida), bugs (Hemiptera), dragonflies (Odonata), spiders (Arachnida); also earthworms, possibly taken on the ground. Principal food formerly palm beetles (*Oryctes*), but destruction of palm trees led to extinction of this prey. Forages mostly in upper two-thirds of trees, preferably among open branches; avoids dense, low vegetation. Gleans leaves, branches and trunks of trees, moving slowly, watching carefully and making short strikes; sometimes probes bark and lichens, and may hover to reach leaves.
Breeding. Sept–Feb; nest-building can begin late Aug and take a month to complete; may be double-brooded. Monogamous; territorial, territory size apparently 6–8 ha. Nest built by both sexes, a small, inconspicuous cup of twigs, moss, lichens and spider webs, usually placed in fork near top of tree, 4–17 m above ground. Eggs 2–3; incubation 3–3·5 weeks; young leave nest at c. 20 days of age, before able to fly. Fledging success 0·93 young/pair.
Movements. Resident; seasonal records from heath attributed to post-breeding dispersal.
Status and Conservation. ENDANGERED. Restricted-range species: present in Réunion EBA. Occurs in only two areas, of increasingly degraded habitat, totalling c. 16 km²; number of mature individuals estimated at 240 in 1991, with stable population, and breeding population estimated at 60–160 pairs in 2000. Occupied habitat possibly suboptimal, and the species seems unable to colonize new areas. Poor breeding success or poor survival, and population fragmentation, may prevent it from spreading. Further habitat loss could therefore be catastrophic; threats to its habitat include degradation from tree-felling, agriculture, development for tourism and recreation, and damage by introduced deer. Forest fires a serious threat; poaching, and nest predation by introduced cats and rats (*Rattus*), may be major problems; other threats are hunting, the introduction of alien predators, and natural disasters such as storms and flooding. In 1999, La Roche Ecrite Reserve (38 km²), which encompasses most of this species' range, was being established, and habitat management planned.

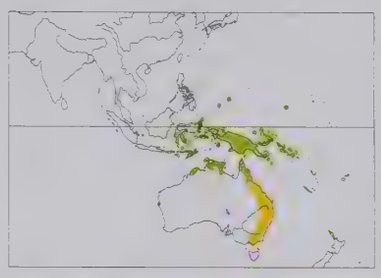
32. **Blackish Cuckoo-shrike**

Coracina coerulescens

French: Échenilleur noir **German**: Glanzraupenfänger **Spanish**: Oruguero Negruzco
Other common names: Philippine/Black Cuckoo-shrike

Taxonomy. *Ceblepyris coerulescens* Blyth, 1842, Luzon, Philippines.
Cebu race (*altera*) extinct. Two extant subspecies recognized.
Subspecies and Distribution.
C. c. coerulescens (Blyth, 1842) – N Philippines (Luzon, Catanduanes).
C. c. deschauenseei duPont, 1972 – Marinduque, in NC Philippines.



Descriptive notes. 25–26 cm. Male nominate race is entirely purplish-black except for slaty-grey rump; iris dark brown; bill and legs black. Female is all dark ashy grey, paler on rump. Juvenile and immature undescribed. Race *deschauenseei* is slightly less purple than nominate. Voice. Loud, harsh single "peeeeeuuuu", sometimes followed by a rapid series of harsh, almost twittering "peeuu-tip-tip-peeuu-tip-tip" lasting up to 9 seconds; often several individuals call together. Also has harsh, repeated twittering "tip-tip-tip-tip".
Habitat. Forest and secondary growth, usually below 1000 m.
Food and Feeding. Food unrecorded; presumably insects. Occurs in canopy and upper understorey in small groups; sometimes joins mixed-species foraging flocks.
Breeding. Oviduct egg in Mar on Luzon. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Luzon EBA and extinct in Cebu EBA. Reckoned to be generally uncommon and local. Cebu race *altera* extinct; not recorded on the island for many years. Nominate race occurs in Quezon National Park, on Luzon.
Bibliography. Collar & Andrew (1988), Collar *et al.* (1994), Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), Gilliard (1950), Goodman & Gonzales (1990), Inskipp *et al.* (1996), Kennedy *et al.* (2000), Mallari *et al.* (2001), Pardo & Gogorza y González (1997), Poulsen (1995), Rabor (1977).

33. **Slender-billed Cicadabird**

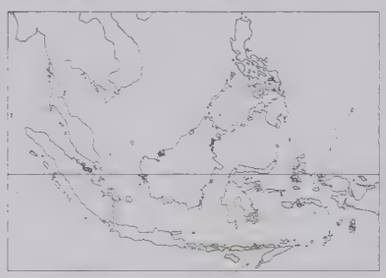
Coracina tenuirostris

French: Échenilleur cigale **German**: Mönchsraupenfänger **Spanish**: Oruguero Picofino
Other common names: Common/Long-billed Cicadabird, Jardine Triller/Caterpillar-eater

Taxonomy. *Gracaulus* [*sic*] *tenuirostris* Jardine, 1831, New South Wales, Australia.
Forms a superspecies with *C. dohertyi*, *C. sula*, *C. dispar* and *C. salomonis*; last two formerly treated as conspecific with present species. Races *salvadorii* and *talautensis* of *C. morio* sometimes treated as races of present species, for no valid reason. Micronesian races (*monacha*, *nesiotis* and *insperata*) probably represent a separate species, and other races likely also to involve more than one species; detailed study of taxonomic limits required. Mainland New Guinea race *muellerii* apparently indistinguishable from migratory Australian nominate race, leading to suggestion that all or most populations of former are migrants from Australia and that taxon should be considered synonymous with nominate; further study needed. Racial identity of birds on Lomblen and of those on Seram Laut uncertain, former tentatively included in *timoriensis* and latter in *amboinensis*; similarly, birds in NE Australia (Cape York Peninsula) presumed to belong with *melvillensis*. Thirty subspecies recognized.
Subspecies and Distribution.
C. t. monacha (Hartlaub & Finsch, 1872) – Palau Is.
C. t. nesiotis (Hartlaub & Finsch, 1872) – Caroline Is (Yap).
C. t. insperata (Finsch, 1876) – Caroline Is (Pohnpei).
C. t. pelingi (Hartert, 1917) – Banggai Is (Peleng, Banggai), off E Sulawesi.
C. t. edithae (Stresemann, 1932) – S Sulawesi.
C. t. pererrata (Hartert, 1917) – Tukangbesi Is (Kaledupa, Tomea), off SE Sulawesi.
C. t. emancipata (Hartert, 1896) – Tanahjampea I (between Sulawesi and Flores).
C. t. kalaotuae (Meise, 1929) – Kalaotoa (N of Flores).
C. t. timoriensis (Sharpe, 1878) – Lesser Sundas (Lomblen, Timor).
C. t. grayi (Salvadori, 1879) – N Moluccas (Morotai, Halmahera, Ternate, Tidore, Bacan).
C. t. obiensis (Salvadori, 1878) – C Moluccas (Bisa, Obi).
C. t. amboinensis (Hartlaub, 1865) – S Moluccas (Ambon, Seram, Seram Laut Is).
C. t. nehrkorni (Salvadori, 1890) – Waigeo I, off W New Guinea.
C. t. numforana J. L. Peters & Mayr, 1960 – Numfoor I, in Geelvink Bay (NW New Guinea).
C. t. meyerii (Salvadori, 1878) – Biak I, in Geelvink Bay.
C. t. muellerii (Salvadori, 1876) – W Papuan Is (Kafiau, Misool), New Guinea (except S) and D'Entrecasteaux Archipelago.
C. t. aruensis (Sharpe, 1878) – Aru Is and coastal SW New Guinea (E to R Fly and Daru I).
C. t. admiralitatis (Rothschild & Hartert, 1914) – Admiralty Is.
C. t. matthiae (Sibley, 1946) – N Bismarck Archipelago (Storm I, St Matthias Is).
C. t. remota (Sharpe, 1878) – Bismarck Archipelago (New Ireland, New Hanover, Feni Is).
C. t. ultima Mayr, 1955 – Tabar, Lihir and Tanga Is (off New Ireland).
C. t. heinrothi (Stresemann, 1922) – New Britain.
C. t. rooki (Rothschild & Hartert, 1914) – Umboi I (W of New Britain).
C. t. tagulana (Hartert, 1898) – Louisiade Archipelago (Misima I, Tagula I).
C. t. rostrata (Hartert, 1898) – Rossel I (E Louisiade Archipelago).
C. t. saturatior (Rothschild & Hartert, 1902) – N & C Solomon Is (Buka I, Bougainville I, Choiseul, New Georgia Group, Santa Isabel).
C. t. nisoria (Mayr, 1950) – SC Solomons (Russell Is).
C. t. erythropygia (Sharpe, 1888) – S Solomons (Guadalcanal, Malaita).
C. t. melvillensis Mathews, 1912 – N Australia from Melville I and Kimberley E to Arnhem Land, also NE Queensland (Cape York Peninsula).
C. t. tenuirostris (Jardine, 1831) – E Australia from E Queensland (S of Cape York Peninsula) S to E New South Wales and E Victoria (Melbourne); non-breeding N to SE New Guinea (where possibly also a resident population).

Descriptive notes. 24–27 cm; 54–76 g. A smallish, slender species with relatively long and thin bill. Male nominate race is predominantly dark slaty grey; lores, cheeks and ear-coverts black; median and greater upperwing-coverts black, edged pale grey, remiges black, primary coverts and primaries narrowly edged grey, secondaries and tertials broadly edged grey (whiter on tertials); rectrices black, glossed green at margins and tipped grey, central pair dark ashy grey with black subterminal spot; underparts, including axillaries and underwing-coverts, dark slaty grey, darker on throat; iris dark brown to black; bill blackish-brown; legs blackish. Distinguished from similar congeners, e.g. *C. morio*, *C. incerta*, *C. schisticeps* and *C. boyeri*, by longish, more slender bill, pale edges of secondaries and slaty-grey lesser wing-coverts. Female is very different, distinctive, ashy brown above, greyer on crown, fawn-buff feather edges on rump and uppertail-coverts; creamy-buff supercilium, black eyeline, white-streaked blackish ear-coverts and face side, creamy-buff cheeks, chin and throat; upperwing-coverts brown, edged fawn-buff, greaters edged light rufous, primary coverts dark brown, remiges dark brown with fawn margins, tertials edged rufous; central pair of rectrices olive-brown, remainder dark brown, tipped fawn-buff, outermost with fawn-buff outer web; underparts creamy white to fawn-buff, with narrow blackish bars (except on undertail-coverts), axillaries and underwing-coverts plain fawn-buff. Juvenile is like female, but tertials tipped white, and feathers of upperparts, upperwing-coverts and remiges edged deep rufous, supercilium rufous, underparts deeper fawn, throat barred; immature differs from adult female in browner crown, brownish bill and legs. Racial variation complex, involving mainly size (including bill), extent of black on head of male, and upperpart colour and occurrence of barring on female: *monacha* female has brownish upperparts, buff underparts with irregular rufous tinge and heavily barred dark brown; *nesiotis* is much larger than previous, female more rufous above and below, barring confined to breast sides; *insperata* female is distinctive, head slate-grey, back grey-brown, wings and tail black with rufous edges, rest of plumage rufous-cinnamon, unbarred, immature entirely rufous-cinnamon with heavy pale buff and black bars above and below; *pelingi* female is unbarred rich cinnamon below; *edithae* female has brown back, is buffy with blackish barring below; *pererrata* female is greyish-brown above, buff and sparsely barred below; *kalaotuae* is like previous but greyer on back; *emancipata* is very large, female light slaty grey above, white with some black barring below; *timoriensis* is rather light in overall colour, with dusky face and throat, female has light grey back and fully blackish-barred white underparts; *grayi* female has olive-brown back, rusty-buff underparts with strong blackish barring; *obiensis* female is reddish olive-brown to tawny-rufous above, unbarred rich cinnamon below; *amboinensis* female is relatively grey above, buff underparts with relatively sparse black barring; *nehrkorni* male has black ear-coverts, chin and throat; *numforana* is rather small, female with little or no barring below; *meyerii* male is dark grey on upperparts, black from chin to breast, female has underparts deep buff to rust-coloured with reduced barring; *aruensis* is very small; *muellerii* is similar to previous but wing longer; *tagulana* is also similar but bill larger; *remota* female is unbarred below; *ultima* female is similarly unbarred below; *rooki* male has black on lores and ear-coverts, very dark throat, female has olive-brown back and pale rust-coloured underparts barred only on undertail-coverts; *heinrothi* resembles previous, but larger, female more barred; *admiralitatis* is very like last two, but smaller than either; *matthiae* is larger and paler than previous, female barred below; *rostrata* has large sharply hooked bill, female deep buff to rust-coloured below and barred black on sides of neck and breast; *saturatior* female has upperparts reddish olive-brown to tawny-rufous, unbarred below; *nisoria* female is barred below (the only Solomons race with barred underparts); *erythropygia* female is unbarred below; *melvillensis* male has black on face not extending to throat, female is mid greyish-fawn above, creamy white with heavy dusky barring below. Voice. In Australia and S New Guinea has staccato buzzing "kree", repeated 8–35 or more times, reminiscent of sound made by cicada (Cicadidae); loud ringing "cree cree" in NE Queensland (*melvillensis*). In Palau Is (*monacha*) a quiet, upslurred whistle, variable, sometimes louder and repeated in song-like fashion. In E Caroline Is (*insperata*) cat-like whistles and low churrs, rolling "preeer" and short "chip-chip-breer". In Admiralty Is (*admiralitatis*) a repeated downslurred "seeu". Other calls (not necessarily by all races) include soft, explosive "twik", and rapid, slightly rolling "chuit" as contact.
Habitat. Tropical and temperate forests, including rainforest, monsoon forest, deciduous vine forest and eucalypt (*Eucalyptus*) forest; also secondary forest, selectively logged forest and forest edge, scrub, open tall woodland, paperbark (*Melaleuca*) swamps, savanna and mangroves. Migrants in New Guinea more or less confined to forest edge, secondary growth, savanna and mangroves, absent from forest interior except on islands. Lowlands and hills, to c. 1500 m.
Food and Feeding. Eats mainly insects, including caterpillars (Lepidoptera), adult and larval beetles (Coleoptera), grasshoppers (Tettigoniidae, Acrididae), crickets (Gryllidae), cicadas (Cicadidae) and ants (Formicidae); sometimes takes fruit and seeds. Found singly or in pairs. Rather unobtrusive; keeps high in trees, gleaning and snatching items from leaves, twigs and bark in tree crowns; rarely at lower levels.
Breeding. Breeds Sept–Mar/Apr in Australia; fledgling in Nov in Admiralty Is (Manus), indicating breeding in Oct. Nest built by both sexes, a very small, shallow bowl of small twigs, dry grass, bark, casuarina (*Casuarina*) needles, lichens and stems, bound with cobwebs and camouflaged on outside with lichen and moss, placed 10–25 m up on fork of horizontal tree branch. Eggs 1; incubation by female only, period 22 days; chick brooded by female, fed by both parents, fledging period 27 days.
Movements. Resident in most of range. In E Australia, S part of population migratory, moving S in Aug–Oct to breed, and with general return movement N in austral winter, from Mar (sometimes Jan); some individuals cross Torres Strait to reach SE New Guinea in non-breeding season.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Generally local and uncommon in Australia, and now only a vagrant at S limit of range (Melbourne area); recorded densities of 0·08–0·5 birds/ha. Uncommon over much of New Guinea, and rare in higher parts of its altitudinal range, but fairly common in S Trans-Fly region and on some islands. Generally uncommon in Wallacea, but moderately common on Halmahera; in S Sulawesi known from only one specimen, collected in 1931. Uncommon but widespread in Solomons Is. In Micronesia (in

On following page: 34. Sumba Cicadabird (*Coracina dohertyi*); 35. Sula Cicadabird (*Coracina sula*); 36. Kai Cicadabird (*Coracina dispar*); 37. San Cristobal Cicadabird (*Coracina salomonis*).



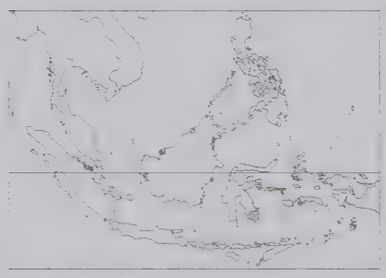
1980s), was uncommon but widespread on Palau, and uncommon in Carolines (rare on Yap). As this species prefers mature forest or older regrowth, it is sensitive to logging in some forest types.
Bibliography. Beehler *et al.* (1986), Beruldsen (1980), Blakers *et al.* (1984), Bowie (1980), Coates (1990, 2001), Coates & Bishop (1997), Cooper (1978), Diamond (2002), Dickinson & Dekker (2002a), Doughty *et al.* (1999), Galbraith & Galbraith (1962), Garnett (1993), Higgins *et al.* (2005), Isherwood *et al.* (1997), Kaestner (1987), Keast (1958), Marchant (1979, 1984, 1985b), Mayr (1955), Mayr & Rand (1937), Mees (1982), Noske *et al.* (1997), Pizzey (1980), Pratt *et al.* (1980), Rand & Gilliard (1967), Schodde & Mason (1999), Strange (2001), White & Bruce (1986).

34. Sumba Cicadabird

Coracina dohertyi

French: Échenilleur de Sumba **German**: Sumbaraupenfänger **Spanish**: Oruguero de Sumba
Other common names: Sumba/Black-barred Cuckoo-shrike, Black-barred Cicadabird

Taxonomy. *Edoliosoma dohertyi* Hartert, 1896, Sumba.
Sometimes retained in the genus *Edoliosoma*. Forms a superspecies with *C. tenuirostris*, *C. sula*, *C. dispar* and *C. salomonis*. Sumbawa population may merit recognition as a distinct race. Monotypic.
Distribution. W Lesser Sunda Is (Sumbawa, Flores, Sumba).



Descriptive notes. 20–24 cm. Male is light bluish-slate above, darker on head and neck; forehead, lores, orbital region, side of head, ear-coverts, chin and throat black; upperwing-coverts light grey; primaries and primary coverts black, inner primaries tipped grey-white, secondaries and tertials black with pale grey margins and greyish-white inner webs; rectrices black, tipped grey, central pair dark grey with black subterminal band and grey tip; underparts, axillaries and underwing-coverts dark grey; iris dark brown, bill black, legs dark grey to blackish. Distinguished from *C. tenuirostris* (of race *emancipata*) by darker edges of upperwing-coverts and secondaries, and black forehead, face and throat. Female differs from male in having white flecks on ear-coverts, more white on edges of secondaries and upperwing-coverts, and white underside with dusky grey barring. Juvenile and immature undescribed. Voice. Harsh call, also described as a pleasant, rasping "queep"; song 3 grating notes, rather like rasp of a cicada (Cicadidae).
Habitat. Primary and tall secondary evergreen forest, monsoon forest and casuarina (*Casuarina*) woodland, from 200 m to 1700 m.
Food and Feeding. Presumably insectivorous. Forages in middle storey and lower canopy of large trees.
Breeding. Breeding condition in Jun. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Northern Nusa Tenggara EBA and Sumba EBA. Generally uncommon. Locally moderately common at 800–1100 m on Sumbawa and Flores.
Bibliography. Andrew (1992), Coates & Bishop (1997), Collar & Andrew (1988), Collar *et al.* (1994), Galbraith & Galbraith (1962), Inskipp *et al.* (1996), Jepson & Monk (1995), Johnstone *et al.* (1996), Jones, Juhaeni *et al.* (1994), Jones, Linsley & Marsden (1995), Mayr (1944), Paynter (1963), Rensch (1931), Strange (2001), Sujatnika *et al.* (1995), White & Bruce (1986).

35. Sula Cicadabird

Coracina sula

French: Échenilleur des Sula **German**: Sularaupenfänger **Spanish**: Oruguero de Sula

Taxonomy. *Edolisoma mindanense sula* Hartert, 1917, Sulabesi, Sula Islands.
Forms a superspecies with *C. tenuirostris*, *C. dohertyi*, *C. dispar* and *C. salomonis*; possibly most closely related to race *pelingi* of *C. teniurostris*. Has sometimes been treated as a race of *C. morio*. Monotypic.
Distribution. Sula Is (Taliabu, Seho, Mangola, Sanana), off E Sulawesi.

Descriptive notes. 20–24 cm. A long-tailed campephagid exhibiting extreme type of sexual convergence, with female plumage almost wholly masculinized. Male is slaty-grey, except for black lores and face, dusky chin and throat. Distinguished from very similar *C. tenuirostris* by somewhat longer tail. Female is very like male, but slightly paler below, and has no black on head. Juvenile reddish-brown but not fully described; immature undescribed. Voice. A series of short, rather explosive, metallic notes at rate of 2–3 per second.
Habitat. Forest , woodland, scrub and plantations, from lowlands to 1400 m.
Food and Feeding. Eats insects, including caterpillars, also small fruits. Frequents mainly lower storeys of forest, up to c. 15 m above ground. Sometimes sallies for insects. Often joins mixed-species foraging flocks.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Banggai and Sula Islands EBA. On Taliabu, common in all lowland wooded habitats, uncommon in primary montane forest to 800 m. Moderately common on Mangola, less so on Sanana.
Bibliography. Andrew (1992), Coates & Bishop (1997), Collar & Andrew (1988), Davidson *et al.* (1995), Dickinson & Dekker (2002a), Dickinson *et al.* (2002a), Holmes & Phillipps (1996), Inskipp *et al.* (1996), Sujatnika *et al.* (1995), White & Bruce (1986).

36. Kai Cicadabird

Coracina dispar

French: Échenilleur des Kaï **German**: Keiraupenfänger **Spanish**: Oruguero de las Kai

Taxonomy. *Edoliosoma dispar* Salvadori, 1878, Kei Bandan, Kai Islands.
Sometimes retained in the genus *Edoliosoma*. Forms a superspecies with *C. tenuirostris*, *C. dohertyi*, *C. sula* and *C. salomonis*. Has been regarded as conspecific with first of those; two individuals of present taxon collected in Seram Laut (Maar I) together with immature male evidently of *C. tenuirostris* (possibly of race *amboinensis*), although identity of latter questionable; considered better to treat present taxon as a separate species, pending resolution of the question of apparent sympatry on Maar. Monotypic.
Distribution. Seram Laut Is (Gorong, Manawoka, Maar, Panjang), Banda Is, Watubela Is (Tiur), Tayandu Is (Manggur), Kai Is, and E Lesser Sundas (Romang, Damar, Tanimbar).

Descriptive notes. 21·5–24·5 cm. Male is glossy black above and below, with bottle-green reflections; iris rather dark brown, bill blackish, and legs black. Differs from *C. tenuirostris* in blacker coloration. Female is olive-brown above, greyer on head, with darker ear-coverts and rufous-buff cheeks, more rufous-brown on upperwing-coverts, dark brown remiges edged rufous, dark brown tail tipped rufous, rufous-buff underparts with dusky blackish cross-lines, bars narrower on undertail-coverts. No information on juvenile and immature plumages. Voice. Male has repeated, unmusical downslurred note; also gives single "chuk".
Habitat. Forest, forest edge and secondary woodland, from lowlands to 1400 m.
Food and Feeding. Presumably eats insects. Forages mainly in middle storey to lower canopy; gleans from undersides of leaves.
Breeding. No information.
Movements. None reported.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Banda Sea Islands EBA. Poorly known. Apparently generally uncommon, but easily overlooked; may be locally numerous. Condition of this species' habitat and any potential threats on some of the islands on which it occurs are entirely unknown.
Bibliography. Andrew (1992), Coates & Bishop (1997), Collar & Andrew (1988), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Collar, Mallari & Tabaranza (1999), Dickinson & Dekker (2002a), Hartert (1903), Inskipp *et al.* (1996), Michaux (1996), Stattersfield & Capper (2000), Sujatnika *et al.* (1995), White & Bruce (1986).

37. San Cristobal Cicadabird

Coracina salomonis

French: Échenilleur de San Cristobal **Spanish**: Oruguero de San Cristóbal
German: San Cristobal-Raupenfänger
Other common names: Makira/San Cristobal Cuckoo-shrike

Taxonomy. *Edoliisoma salomonis* Tristram, 1879, San Cristobal Island, Solomon Islands.
Forms a superspecies with *C. tenuirostris*, *C. dohertyi*, *C. sula* and *C. dispar*; formerly treated as conspecific with first-mentioned. Monotypic.
Distribution. San Cristobal (Makira), in Solomon Is.

Descriptive notes. 26 cm; male 55–75 g, female 61–73 g. Male is grey overall, except for black lores, grey-edged black primary coverts and remiges, entirely black tail; iris very dark brown; bill and legs black. Differs from *C. tenuirostris* in paler coloration. Female has upperparts as male, but lores dark grey, outermost rectrices broadly tipped rufous; entire underparts rich tawny-rufous with no barring. Juvenile has dark grey crown with black and whitish-buff bars, upperparts as female but with black, white and rufous bars on mantle and uppertail-coverts, paler below than female, feathers with blackish shaft streaks and whitish tips, eye dark grey-brown, lower mandible greyish, legs grey; immature like female, but juvenile remiges and rectrices retained. Voice. Song a slightly decelerating series of 7–14 upslurred or downslurred nasal whistles; loud disyllabic calls, "chi-beet" or "pity-you", also loud chatters.
Habitat. Inhabits forest and secondary forest, but uncommon in secondary scrub; recorded up to at least 900 m.
Food and Feeding. No information on diet. Forages in twos or threes in dense foliage, sometimes with mixed flocks, especially with drongos (*Dicrurus*).
Breeding. No information.
Movements. No information.
Status and Conservation. Not globally threatened. Restricted-range species: present in the Solomon Group EBA. Fairly common within its single-island range.
Bibliography. Dutson (2005a), Galbraith & Galbraith (1962), Mayr (1955, 1978).

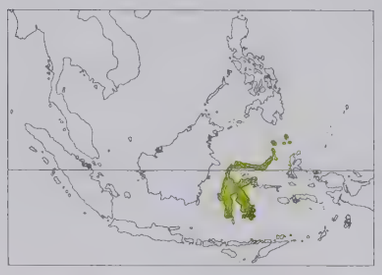
38. Black-bibbed Cicadabird

Coracina mindanensis

French: Échenilleur à menton noir **Spanish**: Oruguero Filipino
German: Philippinenraupenfänger
Other common names: Black-bibbed Cuckoo-shrike, Philippine Cicadabird

Taxonomy. *Volvocivora mindanensis* Tweeddale, 1879, Zamboanga, Mindanao, Philippines.
Forms a superspecies with *C. morio*, *C. ceramensis* and *C. incerta*, and all sometimes considered conspecific. Five subspecies recognized.
Subspecies and Distribution.
C. m. lecroyae Parkes, 1971 – Luzon, in N Philippines.
C. m. elusa (McGregor, 1905) – Mindoro.
C. m. ripleyi Parkes, 1971 – Samar, Biliran, Leyte and Bohol.
C. m. mindanensis (Tweeddale, 1879) – Mindanao and Basilan.
C. m. everetti (Sharpe, 1893) – Sula Archipelago (Jolo, Lapac, Tawi-Tawi, Bongao), in SW Philippines.



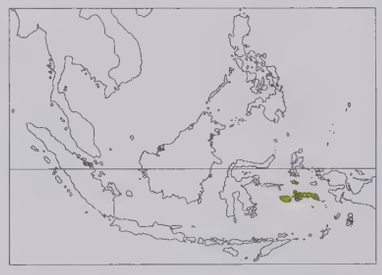
Descriptive notes. 23 cm. Male nominate race has forehead, side of face, chin, throat and foreneck black; crown and upperparts, including upperwing-coverts, light slaty blue, lighter on rump and very pale on uppertail-coverts, latter edged whitish; greater coverts and tertials externally pale grey; alula and primary coverts black, primaries and secondaries black, edged and tipped slaty grey; rectrices black, edged grey at tip; black of lower foreneck shades to light slaty blue on underparts, including underwing-coverts and axillaries, becoming pale ashy grey on lower belly to undertail-coverts; iris dark brown; bill and legs black. Differs from *C. striata* in smaller size, black face and throat. Female has no black on head but dusky spot in front of eye; paler blue-grey above than male, becoming silvery grey from lower back to uppertail-coverts; edges of greater coverts, secondaries and tertials lighter grey than back, tail mainly black but ashy grey at base; underparts plain ashy grey, whiter on lower abdomen and undertail-coverts, with light pearl-grey underwing-coverts and axillaries. Juvenile and immature undescribed. Races differ in size and in shade of grey areas: *ripleyi* is closest to nominate, but wing and tail on average longer, male grey areas paler, rump paler than back (but not so pale as nominate), female rump usually pale grey (rather than whitish) and lower underparts light grey (not white), both sexes with terminal black band on central rectrices narrower; *elusa* darker and more uniform, showing less contrast in plumage, rump only slightly paler than back, wing edgings concolorous with body; *everetti* is extremely similar to previous, differing only in smaller size; *lecroyae* is also similar, but wing and, especially, tail shorter, plumage generally somewhat paler grey, edges of wing-coverts and remiges much paler (even whitish in female). Voice. Insufficient information.
Habitat. Forest, secondary growth; mostly at lower elevations, below 1000 m.
Food and Feeding. Food not recorded; presumably insects. Occurs singly, in small groups or with mixed-species flocks; inconspicuous and quiet, keeping to canopy.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Poorly known. Uncommon to rare; possibly overlooked. Considered very rare on Luzon (race *lecroyae*); was not common in mid-1950s on Mindoro (*elusa*); locally fairly common on Mindanao (nominate); no information on status of *everetti* in Sula Is. Race *ripleyi* rare on Samar and Bohol, presumably also on Biliran and Leyte; very occasionally recorded in Rajah Sikatuna National Park (Bohol). This species' preference for lower-altitude forest suggests that it must have suffered population declines, possibly on a fairly large scale, following the widespread destruction of lowland forest throughout the Philippines.
Bibliography. Anon. (1997b), Brooks, Dutson, King & Magsalay (1996), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Collar, Mallari & Tabaranza (1999), Delacour & Mayr (1946), Dickinson & Dekker (2002a), Dickinson *et al.* (1991), duPont & Rabor (1973a), Dutson *et al.* (1992), Gilliard (1950), Inskipp *et al.* (1996), Kennedy *et al.* (2000), Mallari *et al.* (2001), Pardo & Gogorza y González (1997), Parkes (1971), Rand & Rabor (1960), Ripley & Rabor (1958), Stattersfield & Capper (2000), White & Bruce (1986).

39. Sulawesi Cicadabird

Coracina morio

French: Échenilleur morio **German**: Morioraupenfänger **Spanish**: Oruguero de Célebes
Other common names: Sulawesi Cuckoo-shrike, Celebes/Mueller's/Dark-grey Cicadabird

Taxonomy. *Ceblepyris morio* S. Müller, 1843, near Gorontalo and Tondano, north Sulawesi.
Forms a superspecies with *C. mindanensis*, *C. ceramensis* and *C. incerta*, and all sometimes considered conspecific. *C. sula* has sometimes been treated as a race of present species. Races *salvadorii* and *talautensis* sometimes included in *C. tenuirostris*, for no apparent valid reason. Nominate race varies clinally, with size of male's black throat patch decreasing and paleness of female plumage increasing from N to S; birds from S Sulawesi often separated as race *wiglesworthi*, but populations with intermediate characters occur in parts of C & SE Sulawesi. Three subspecies currently recognized.
Subspecies and Distribution.
C. m. salvadorii (Sharpe, 1878) – Sangihe Is.
C. m. talautensis (A. B. Meyer & Wiglesworth, 1895) – Talaud Is (Karakelong, Salebabu, Kaburuang).
C. m. morio (S. Müller, 1843) – N, C, S & SE Sulawesi, including smaller islands of Lembeh, Tobea, Kabaena, Muna, Buton.
Descriptive notes. 23–25 cm; 50–67 g. Male nominate race is dark bluish-slate overall, darker on head, with lores, face, chin, throat and upper breast black (throat patch largest in N of range); median and greater upperwing-coverts grey, margined paler, alula black, primary coverts and remiges



black, edged grey to blue-grey; rectrices black, tipped white, central pair grey with black tips; underwing-coverts and axillaries dark bluish-slate; iris dark brown; bill and legs black. Female is paler grey above (palest in S) than male, no black on head, throat or breast, has lores white, eyering buffy white, blackish spot in front of eye, grey head side mottled white; most of underparts, including axillaries and also underwing-coverts, cinnamon or deep ochraceous, barred black. Juvenile and immature undescribed. Race *salvadorii* is largest, male more smoky grey than nominate, including on throat, female buffy white below; *talautensis* is intermediate in size, female underparts pale buffy and more closely barred. Voice. Song of male a slow sequence of buzzy, nasal, ringing notes, like sound made by cicada (Cicadidae), alternating with clear, descending whistle. Also gives bursts of excited, piercing "ki" or "ke" calls, rapid, nasal chatter, and low-pitched nasal "chup".
Habitat. Primary and tall secondary lowland, hill and montane forest, forest edge, small forest patches and secondary growth; to 1770 m on Sulawesi.
Food and Feeding. Eats insects. Occurs in pairs or small groups, also in mixed-species foraging flocks. Gleans quietly but actively in canopy and subcanopy.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Widespread, and locally moderately common, on Sulawesi. Common on Talaud Is; uncommon on Sangihe. Occurs in Lore Lindu National Park, on Sulawesi.
Bibliography. Andrew (1992), Baltzer (1990), Catterall (1997), Coates & Bishop (1997), Coles (1976), Dickinson & Dekker (2002a), Holmes & Phillipps (1996), Inskipp *et al.* (1996), Michaux (1998), Parkes (1971), Rabor (1977), Riley (1997a), Stresemann (1938, 1940), Wardill (1995), Watling (1983a), White & Bruce (1986).

40. Pale Cicadabird

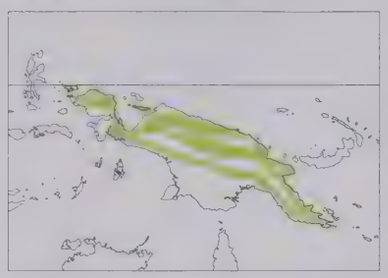
Coracina ceramensis

French: Échenilleur pâle **German**: Blassraupenfänger **Spanish**: Oruguero Pálido
Other common names: Moluccan/Pale-grey Cicadabird

Taxonomy. *G[raucalus] ceramensis* Bonaparte, 1850, Seram, Moluccas.
Forms a superspecies with *C. mindanensis*, *C. morio* and *C. incerta*, and all sometimes considered conspecific. Validity of race *hoogerwerfei* uncertain; further study needed. Proposed race *marginata* (from Buru and Boano) considered indistinguishable from nominate. Two subspecies currently recognized.
Subspecies and Distribution.
C. c. hoogerwerfei (Jany, 1955) – Obi I, in Moluccas.
C. c. ceramensis (Bonaparte, 1850) – Buru, Seram and Boano I.

Descriptive notes. 24–25 cm. Male nominate race is light slaty grey above, with lores black; upperwing-coverts black, outer webs lighter slaty grey than upperparts, greater coverts edged white; alula black, primary coverts black, edged grey; remiges black, primaries edged grey, secondaries edged whitish; rectrices black, ashy grey at tip, central two feathers light slaty grey with black subterminal spot; chin blackish; slaty grey below, darker on throat, lighter on underwing-coverts; iris dark brown, bill blackish, legs black. Differs from *C. tenuirostris* (e.g. of race *amboinensis*) in smaller size, paler underparts. Female resembles male, but much paler below, with throat and undertail-coverts almost whitish. Juvenile is paler than female, with sparse black shaft streaking on breast and flanks; immature not fully described. Race *hoogerwerfei* is said to be purer grey dorsally and paler below than nominate. Voice. Rapid dry chatter and a short "tick"; flight call a distinctive nasal chatter.
Habitat. Forest, including selectively logged forest, secondary growth and occasionally mangroves; sea-level to 1750 m.
Food and Feeding. Takes insects. Usually found with mixed-species foraging flocks in densely foliaged crowns of tall trees; forages actively, gleaning from branches and from undersides of leaves.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Buru EBA, Seram EBA and Northern Maluku EBA. Not well known. Moderately common on Buru and Seram; apparently very uncommon on Obi.
Bibliography. Andrew (1992), Bowler & Taylor (1989), Coates & Bishop (1997), Dickinson & Dekker (2002a), Dickinson *et al.* (2002a), Hartert (1903), Inskipp *et al.* (1996), Isherwood *et al.* (1997), Michaux (1998), Sujatnika *et al.* (1995), White & Bruce (1986).

41. Black-shouldered Cicadabird



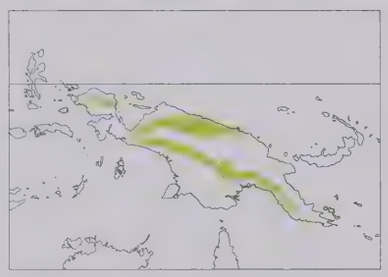
Coracina incerta

French: Échenilleur à épaulettes noires **Spanish**: Oruguero Incierto
German: Schwarzschulter-Raupenfänger
Other common names: Black-shouldered Cuckoo-shrike, Papuan/Sharpe's Cicadabird

Taxonomy. *Campephaga incerta* A. B. Meyer, 1874, Ansus, Yapen Island, north-west New Guinea.
Forms a superspecies with *C. mindanensis*, *C. morio* and *C. ceramensis*, and all sometimes considered conspecific. Monotypic.

On following page: 42. Grey-headed Cuckoo-shrike (*Coracina schisticeps*); 43. New Guinea Cuckoo-shrike (*Coracina melas*).

Distribution. W Papuan Is (Waigeo, Batanta), mountains throughout New Guinea, and islands in Geelvink Bay (Meos Num I, Yapen I).



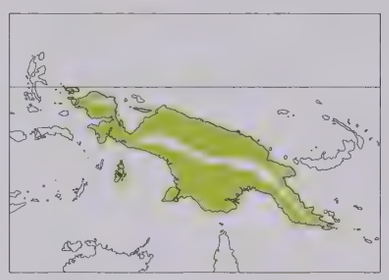
Descriptive notes. 21–22 cm; 53–60 g. Male is slaty blue above, with lores, chin and feathers under eye black, ear-coverts and throat tinged blackish; upperwing-coverts, alula and remiges black, median and greater coverts and secondaries edged slaty blue; tail black, tipped ashy grey, outermost feather with ash-grey outer web, central two feathers ashy grey with subterminal black spot; entire underparts slaty blue, underwing-coverts and axillaries ashy grey; iris dark brown; bill and legs black. Differs from similar *C. tenuirostris* in smaller size, shorter bill, dark "shoulder". Female is very like male but paler, axillaries and underwing-coverts barred grey and white, lacks black spot on central rectrices. Juvenile undescribed; immature like female, but ear-coverts, chin and throat streaked or flecked whitish, axillaries almost white, barred grey, lower abdomen indistinctly barred pale grey. Voice. Song a series of 5–30 disyllabic, buzzy notes like sound of a cicada (Cicadidae), "weeyu-weeyu-weeyu" and so on; also has whistled "chewit" contact call.
Habitat. Hill forest and lower montane forest, forest edge and secondary growth, at 100–1800 m, usually 450–1450 m.
Food and Feeding. Eats arthropods, including caterpillars and katydids (Tettigoniidae); also fruit. Forages in upper tree levels; perches on branches in outer canopy and peers at overhead foliage; occasionally hover-gleans.
Breeding. Females in breeding condition in Oct–Nov. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Widely distributed but local; fairly common to scarce. Poorly known species.
Bibliography. Andrew (1992), Beehler (1978a), Beehler *et al.* (1986), Coates (1990), Diamond, J.M. (1972, 1985), Gilliard & LeCroy (1961), Gregory (1995), Mayr & Rand (1937), Rand & Gilliard (1967), Ripley (1964), Rothschild (1916).

42. Grey-headed Cuckoo-shrike

Coracina schisticeps

French: Échenilleur de Gray **German**: Grayraupenfänger **Spanish**: Oruguero Cabecigrís
Other common names: Gray's/New Guinea/Slaty/Black-tipped Cuckoo-shrike

Taxonomy. *Campephaga schisticeps* G. R. Gray, 1846, Triton Bay, south-west New Guinea.
Four subspecies recognized.
Subspecies and Distribution.
C. s. schisticeps (G. R. Gray, 1846) – Misool I and NW New Guinea (E to head of Geelvink Bay and Etna Bay; possibly also W Papuan Is (Waigeo, Batanta).
C. s. reichenowi (Neumann, 1917) – N New Guinea from Geelvink Bay E to Sepik Valley.
C. s. poliopsa (Sharpe, 1882) – S New Guinea from R Kaspare E to Astrolabe Mts.
C. s. vittata (Rothschild & Hartert, 1914) – D'Entrecasteaux Archipelago (Goodenough I, Ferguson I).



Descriptive notes. 21–22 cm; 48–57 g. Male nominate race has crown and upperparts, including lesser and median upperwing-coverts, slaty grey, side of head darker grey, feathers in front of eye, cheeks and chin blackish; greater coverts paler grey; alula, primary coverts and primaries black; secondaries and tertials black, broadly edged grey; tail black, tipped ashy grey, central two feathers dark ashy grey with subterminal black band; underparts slaty grey, axillaries and underwing-coverts slaty grey; iris dark brown; bill and legs black. Distinguished from very similar *C. tenuirostris* by smaller size, shorter bill, less distinct paler edges of secondaries; from *C. morio* by lack of black "shoulder". Female has crown to nape slaty grey, feathers in front of eye blackish, head side rufous, upperparts rufous-brown, more chestnut on rump and uppertail-coverts, flight-feathers blackish-brown, broadly edged rufous-brown on secondaries and tertials, tail black, tipped rufous-buff, central two feathers rufous-brown with black tips; cheeks and entire underparts, including axillaries and underwing-coverts, bright chestnut. Juvenile undescribed; immature like female, subadult male a mixture of grey and rufous. Race *reichenowi* has blacker chin than nominate, female has rufous crown and nape; *poliopsa* female similar to nominate female, but slate-grey extends down from crown to ear-coverts and chin; *vittata* female has slate-grey ear-coverts and chin, black ventral barring. Voice. Vocal and conspicuous. Male has musical "chickity-choo", female answers with nasal upslurred "weeh weeh"; also has rapid nasal slurs followed by chattering.
Habitat. Forest, forest edges and tall secondary growth; sea-level to 1500 m, mainly 150–1200 m.
Food and Feeding. Eats mainly fruit; also insects, including caterpillars. Gregarious and vocal; forages mainly in canopy, occasionally in middle level.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Status poorly known. Regarded as locally common.
Bibliography. Andrew (1992), Beehler *et al.* (1986), Coates (1990), Diamond, J.M. (1972, 1985), Diamond, J.M. & Terborgh (1968), Gregory (1995), Mees (1965), Rand & Gilliard (1967), Ripley (1964).

43. New Guinea Cuckoo-shrike

Coracina melas

French: Échenilleur mélanure **German**: Stahlraupenfänger **Spanish**: Oruguero Negro
Other common names: (New Guinea) Black Cuckoo-shrike/Greybird

Taxonomy. *Lanius melas* Lesson, 1828, Dorey, north-west New Guinea.
Race *batantae* often merged with nominate. Species name often incorrectly given as *melaena*, but original name is a transliterated Greek word and thus remains invariable. Six subspecies currently recognized.
Subspecies and Distribution.
C. m. waigeuensis (Stresemann & Paludan, 1932) – Waigeo I, off NW New Guinea.
C. m. batantae (Gyldenstolpe & Mayr, 1955) – Batanta I (W Papuan Is).
C. m. melas (Lesson, 1828) – Salawati I (W Papuan Is) and N & W New Guinea (E to Astrolabe Bay and, in S, to R Eilanden).
C. m. tommasonis (Rothschild & Hartert, 1903) – Yapen I, in Geelvink Bay.
C. m. meeki (Rothschild & Hartert, 1903) – E New Guinea (E from Huon Gulf and R Fly).
C. m. goodsoni (Mathews, 1928) – Aru Is.

Descriptive notes. 23 cm; 56–63 g. Male nominate race is entirely black with purplish gloss; iris dark brown; bill and legs black. Female is bright rufous-brown, darker on upperparts, with ear-coverts and cheeks even darker, streaked pale, lores black, pale ochraceous stripe over eye, duller brown upperwing-coverts and remiges. Juvenile undescribed; immature like female, and subadult male mottled black and rufous. Races differ mainly in overall shade and richness of colour of female plumage, especially underparts: *meeki* is palest; *goodsoni* and *waigeuensis* are darkest, female of latter also has barring on flanks; *tommasonis* is brightest; *batantae* similar to *waigeuensis*, but female apparently lacks barring. Voice. A loud, slow series of liquid, downslurred whistling notes, "deer" or "tieeuw"; flock call a nasal, rapidly repeated "whit"; also has nasal "wutchay", sometimes repeated in chattering series.
Habitat. Rainforest and monsoon forest; locally also gallery and mangrove forests; normally in forest interior, but visits edges and adjacent secondary growth, disturbed areas and teak (*Tectona*) plantations. Mainly lowlands to 750 m, locally to 1250 m.
Food and Feeding. Feeds mainly on adult and larval insects, including lepidopteran larvae; also takes fruit. Usually in pairs or in parties of up to ten individuals, foraging quietly in subcanopy and in smaller branches of lower trees; also commonly joins mixed-species foraging flocks in middle storey. Active, moving quickly from perch to perch, gleaning from branches and leaves; occasionally sallies.
Breeding. Nest-building in Nov. One nest was built by both adults, described as typical of genus, placed 27 m up and near outer foliage on sturdy horizontal fork of branch. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Widespread on mainland, where common in lowlands but uncommon to rare at higher elevations; no information on status of island populations. Density in rainforest estimated at 6 birds/10 ha.
Bibliography. Andrew (1992), Beehler (1978a), Beehler *et al.* (1986), Bell (1982b), Coates (1990), David & Gosselin (2002a), Diamond (1972, 1987), Gregory (1995), Mack *et al.* (2000), Mathews (1928), Mayr & Rand (1937), Rand & Gilliard (1967), Ripley (1964), Sibley & Monroe (1990).

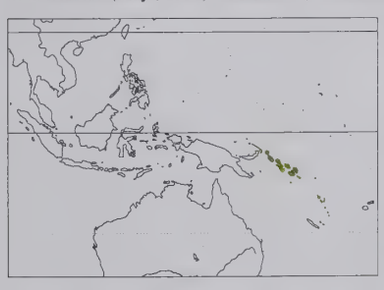
44. Black-bellied Cuckoo-shrike

Coracina montana

French: Échenilleur à ventre noir **German**: Bergraupenfänger **Spanish**: Oruguero Ventrinegro
Other common names: Mountain Cuckoo-shrike, Black-bellied Greybird

Taxonomy. *Campephaga montona* [*sic*] Meyer, 1874, Arfak Mountains, New Guinea.
Two subspecies recognized.
Subspecies and Distribution.
C. m. montana (Meyer, 1874) – mountains of W & C New Guinea (Vogelkop and C range).
C. m. bicinia Diamond, 1969 – mountains of N New Guinea (Cyclops, Bewani and Torricelli).



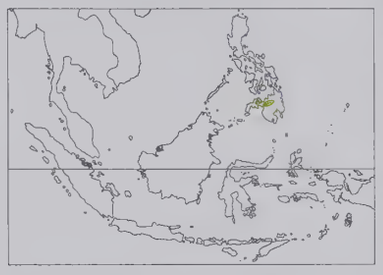
Descriptive notes. 24 cm; 57–70 g. Male nominate race has blue-grey crown and upperparts, including most of upperwing-coverts, black greater coverts broadly edged grey; alula and flight-feathers deep glossy black, tertials edged grey; rectrices black, glossed green at edges; forehead, lores, side of face, neck side, throat and entire underparts, including underwing-coverts and axillaries, glossy black, thighs grey; iris dark brown; bill and legs grey to blackish. Differs from extremely similar *C. holopolia* in having pale grey edging restricted to tertials. Female is like male, but paler blue-grey above and below, has only base of forehead, lores and chin black. Juvenile apparently has rufous undertail-coverts, barred dark slaty grey; immature like female, but tertials and outer rectrices tipped white, chin and throat grey, variable fine barring on head, breast and undertail-coverts (may be absent). Race *bicinia* is larger than nominate, black of chin and throat more extensive. Voice. Vocal; has conspicuous antiphonal duet, male giving a rising and falling, nasal, whistled note, female responding with 2–3 rapid, buzzy, downslurred notes; duet repeated for 8–10 seconds. Often calls in flight.
Habitat. Forest, forest edges (not secondary growth), clearings and gardens; mountains at 750–2800 m, mainly 1000–2450 m.
Food and Feeding. Eats fruit, including figs (*Ficus*); also insects, including caterpillars. Usually in pairs or in parties of 3–4 individuals. Forages in canopy, occasionally lower, continually moving and calling; flutters among and under small leaves when seeking insects.
Breeding. Laying female in Oct and dependent fledgling in Sept indicate breeding in late dry season to early wet season. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Generally fairly common. Little recent information.
Bibliography. Andrew (1992), Beehler (1978a), Beehler *et al.* (1986), Coates (1990), Diamond (1969, 1972), Diamond & Terborgh (1968), Gilliard & LeCroy (1961), Mack *et al.* (2000), Mayr & Rand (1937), Pratt (1982), Rand & Gilliard (1967), Ripley (1964), Strange (2001).

45. Solomon Cuckoo-shrike

Coracina holopolia

French: Échenilleur des Salomon **Spanish**: Oruguero de las Salomón
German: Salomonenraupenfänger
Other common names: Solomon (Islands) Cicadabird, Black-bellied Cuckoo-shrike(!)/Cicadabird

Taxonomy. *Graucaulus holopolius* Sharpe, 1888, Guadalcanal, Solomon Islands.
Three subspecies recognized.
Subspecies and Distribution.
C. h. holopolia (Sharpe, 1888) – Solomon Is (Buka, Bougainville, Choiseul, Santa Isabel, Guadalcanal).
C. h. pygmaea (Mayr, 1931) – C Solomons (Kolombangara, New Georgia, Vangunu, Gatukai).
C. h. tricolor (Mayr, 1931) – Malaita I (S Solomons).



Descriptive notes. 20–23 cm; 41–47 g. Male nominate race has crown and upperparts, including upperwing-coverts and tertials, grey, variable black nuchal collar (sometimes more or less absent); alula, remiges and tail black, primary coverts, primaries and secondaries edged grey; base of forehead, head side, neck side, throat and entire underparts black; iris dark brown; bill and legs black. Distinguished from extremely similar *C. montana* by having broad pale grey edging on secondaries and tertials. Female is generally grey, including on head, with wings as male, tail darker grey, becoming black towards tip, outer feathers broadly tipped grey; eye mid-grey. Juvenile has body fawn-coloured with brown barring, underparts boldly barred, remiges fuscous, edged and tipped fawn, central two rectrices grey, others browner than adult's and tipped fawn; immature like adult, but throat, breast, undertail-coverts, underwing-coverts and axillaries boldly barred black and white, grading into grey with narrow white bars on flanks and belly, also with white flecks on auriculars. Race *tricolor* is smaller than nominate, male has broad black forehead, broad black nuchal collar, no grey on edges of primaries and primary coverts, and very pale grey upperwing-coverts and edges of secondaries; *pygmaea* is much smaller than nominate, darker grey on upperparts, and with restricted black on forehead and nuchal collar. Voice. Rasping or quavering upslurred "vrhee", "vvrreeeoo" or "toe-hee", often repeated up to ten times, in case of race *pygmaea* notes downslurred, decelerating and dropping in pitch; harsh chattering "chur-chur-ur-ur".
Habitat. Forest and forest edge, from sea-level to 950 m.
Food and Feeding. Apparently eats mainly insects, but also takes fruit. Occurs in canopy, in groups of up to eight individuals birds; commonly joins mixed-species foraging flocks. Much prey taken by sallying or hovering.
Breeding. Female in breeding condition in Aug on Bougainville. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in the Solomon Group EBA. Generally rather scarce, but regarded as fairly common on Bougainville and Buka I; most common in hills. Degree to which it is able to survive in logged and degraded forest is poorly known. Lowland forest throughout the region is threatened by widespread logging; as a large proportion of this species' population appears to inhabit forest unsuitable for logging, however, its numbers are probably declining only relatively slowly.
Bibliography. Buckingham *et al.* (1995), Cain & Galbraith (1956), Coates (1990), Doughty *et al.* (1999), Dutson (2005b), Galbraith & Galbraith (1962), Hadden (1981), Kaestner (1987), Mayr (1931, 1955), Schodde (1977), Stattersfield & Capper (2000), Webb (1992).

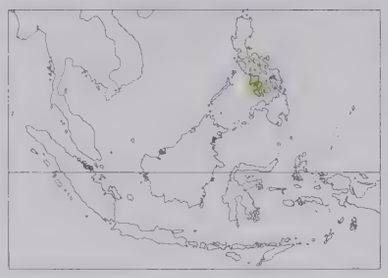
46. McGregor's Cuckoo-shrike

Coracina mcgregori

French: Échenilleur de McGregor **Spanish**: Oruguero de McGregor
German: Spitzschwanz-Raupenfänger
Other common names: Sharp-tailed Cuckoo-shrike

Taxonomy. *Malindangia mcgregori* Mearns, 1907, Mount Malindang, Mindanao, Philippines.
Birds from Bukidnon ranges described as race *peterseni* on basis of paler underparts, but considered indistinguishable from birds elsewhere in species' range. Monotypic.
Distribution. Mountains of WC Mindanao (Malindang and Bukidnon), in S Philippines.

Descriptive notes. 21 cm; 39–47·5 g. A relatively small cuckoo-shrike. Male has forehead, lores, face, chin, throat and upper breast bluish-black; crown to rump grey, becoming paler on rump and uppertail-coverts; upperwing-coverts grey, outer webs of median and greater coverts white (broad white wingbar); remiges black, primaries margined white; rectrices black, edged and tipped white on outers, central pair grey; lower breast grey, becoming white on belly and undertail-coverts; iris dark brown; bill black; legs blackish-grey. Distinguished from similar *C. ostenta* by paler overall coloration, pattern of white wingbar, and less extensive black on underparts. Female is like male, but black on head paler, almost dark grey. Juvenile has upperparts and breast grey, mottled black and with buff feather edges, belly feathers with dark shaft streaks; immature not fully described. Voice. Call of one or more notes, often continuing for several minutes, some notes raspy, "chu chu chu zwheeeeeeet zhuuuuuuuu", likened to sounds made when tuning a radio; also repeated "zwheeet".
Habitat. Montane mossy forest and forest edge, at 1000–1900 m.
Food and Feeding. Food undescribed; presumably insects. Forages in groups in canopy or understorey; also joins mixed-species flocks.
Breeding. Recently fledged young in Mar; birds with enlarged gonads in Apr–Jun. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Mindanao and the Eastern Visayas EBA. Known from at least eight general mountain-range localities; common within its small range. Much forest above 1300 m now seriously threatened by clearance at one locality (Mt Kitanglad); in general, however, forest at elevations occupied by this species is fairly secure.
Bibliography. Anon. (1997b), Collar & Andrew (1988), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Collar, Mallari & Tabaranza (1999), Delacour & Mayr (1946), Dickinson *et al.* (1991), Gonzalez & Mallari (1993), Heaney *et al.* (1993), Inskipp *et al.* (1996), Kennedy *et al.* (2000), Lambert (1993), Mallari *et al.* (2001), McGregor (1921), Meyer de Schauensee & duPont (1962), Pardo & Gogorza y González (1997), Rabor (1977), Rand & Rabor (1960), Ripley & Rabor (1961), Salomonsen (1953), Stattersfield & Capper (2000).



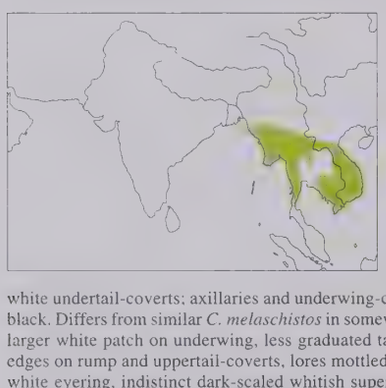
47. White-winged Cuckoo-shrike

Coracina ostenta

French: Échenilleur à ailes blanches **Spanish**: Oruguero Aliblanco
German: Spiegelraupenfänger
Other common names: Philippine Cuckoo-shrike

Taxonomy. *Coracina ostenta* Ripley, 1952, Panay and Guimaras, Philippines.
Species previously known as *C. panayensis*, but that name preoccupied by a race of *C. striata*. Monotypic.
Distribution. Panay, Guimaras (probably extinct) and Negros, in WC Philippines.
Descriptive notes. 25 cm. Distinctive. Male has forehead, lores, face, chin, throat and upper breast black; crown dark grey, upperparts dark grey, becoming light grey on rump and uppertail-coverts; wings black, broad white edges of greater upperwing-coverts and tertials (prominent white wingbar); rectrices black, tipped white, tips becoming broader on outer feathers, outermost wholly edged white; breast to belly dark grey, becoming lighter towards vent, white on undertail-coverts; underwing-coverts white; iris dark brown; bill and legs black. Female is similar to male, but has lores and forehead dark grey, upperparts dark bluish-grey, underparts light grey. Juvenile and immature undescribed. Voice. Has loud, sharp downward-inflected "schiirp" or "pi-ieu", often repeated 10–20 times; also a longer series of notes, rendered "chu chu chu chu pi-ieuu ki chu".
Habitat. Lowland and mid-montane forest, usually below 1100 m, rarely to 2150 m; also at forest edge and in secondary forest.

On following pages: 48. Indochinese Cuckoo-shrike (*Coracina polioptera*); 49. Black-winged Cuckoo-shrike (*Coracina melaschistos*); 50. Lesser Cuckoo-shrike (*Coracina fimbriata*); 51. Black-headed Cuckoo-shrike (*Coracina melanoptera*).



Food and Feeding. Eats adult and larval insects, including orthopterans. Found in upper storey of large trees, foraging mainly in canopy; also joins mixed-species foraging flocks.
Breeding. Recorded in Feb–Mar, Jul and Sept on Panay; juveniles being fed by adults in May on Negros. Nest undescribed, placed up to 20 m above ground on forked branch of tall tree. Eggs 2–3; chicks fed by both parents. No other information.
Movements. None recorded; some seasonal altitudinal migration may occur.
Status and Conservation. VULNERABLE. Restricted-range species: present in Negros and Panay EBA. Has small range (23,000 km²) which is fragmented, and throughout which habitat degradation, particularly the selective logging of large trees, poses serious threat to remaining forest fragments. Global population estimated at fewer than 10,000 individuals, and declining. Was formerly widespread on Negros; now restricted to seven known localities, where it is still locally common. Much scarcer on Panay, with recent records from only three localities in W of island. Presumed extinct on Guimaras as a result of chronic deforestation; has not been recorded there for over a century. This species is suffering a rapid population decline following extensive loss and degradation of forest habitat at low to middle altitudes; in 1988, estimated that only 4% of Negros and 8% of Panay remained forested. Much of the forest left on Panay and Negros lies above the species' altitudinal limit; significant populations unlikely to survive in montane forest, and it lives at relatively low densities in secondary forest. Occurs in Mount Canlaon Natural Park (Negros) and in the North Negros Forest Reserve; the latter is only nominally protected. Also found in the proposed Panay Mountains National Park, which apparently contains the largest block of forest remaining in the W Visayas, and at Mt Talinis–Twin Lakes (Negros), both of which receive conservation funding.
Bibliography. Anon. (1997b), Brooks *et al.* (1992), Collar & Andrew (1988), Collar, Andreev et al. (2001), Collar, Crosby & Stattersfield (1994), Collar, Mallari & Tabaranza (1999), Dickinson, Dekker et al. (2002a), Dickinson, Kennedy & Parkes (1991), Erickson & Heideman (1983), Evans, Dutson & Brooks (1993), Inskipp *et al.* (1996), Kennedy *et al.* (2000), Lambert (1993), Mallari *et al.* (2001), Pardo & Gogorza y González (1997), Parkes (1971), Rabor (1977), Stattersfield & Capper (2000).

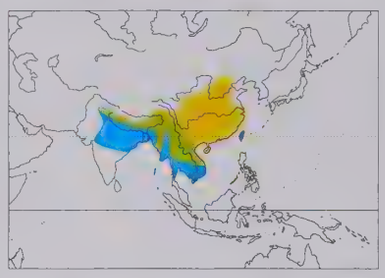
48. Indochinese Cuckoo-shrike

Coracina polioptera

French: Échenilleur indochinois **German**: Gartenraupenfänger **Spanish**: Oruguero de Indochina

Taxonomy. *Campophaga polioptera* Sharpe, 1878, Cochinchina.
Formerly sometimes treated as conspecific with *C. fimbriata*. Three subspecies recognized.
Subspecies and Distribution.
C. p. indochinensis (Kloss, 1925) – W, C & E Myanmar, NW & E Thailand (S to Kamphaeng Phet), C & S Laos and SC Vietnam.
C. p. polioptera (Sharpe, 1878) – SE Myanmar, SW Thailand (from Kanchanaburi S to Isthmus of Kra), Cambodia and extreme S Vietnam (Cochinchina).
C. p. jabouillei Delacour, 1951 – C Vietnam (N & C Annam).

Descriptive notes. 21–23 cm; mean 35·8 g (Thailand). Male nominate race has crown and upperparts, including upperwing-coverts, ashy grey, darker on head, paler on median and greater wing-coverts, rump and uppertail-coverts; lores and ear-coverts slightly dusky; alula, primary coverts and primaries black, narrowly edged grey to white, primaries broadly white on inner webs (white patch on underwing visible in flight); secondaries and tertials black, with grey outer webs; rectrices black, broadly tipped white, central pair ashy grey, becoming black towards tip; light grey below, darker on throat and paling towards abdomen and vent, white undertail-coverts; axillaries and underwing-coverts light grey; iris red to brown; bill and legs black. Differs from similar *C. melaschistos* in somewhat paler general coloration, pale wing edgings, larger white patch on underwing, less graduated tail. Female is like male, but has whitish feather edges on rump and uppertail-coverts, lores mottled white, ear-coverts grey with white streaks, thin white eyering, indistinct dark-scaled whitish supercilium, entirely dull white and barred blackish below (barring sometimes reduced or absent); rectrix R2 black with ashy-grey outer web and white tip. Juvenile is irregularly barred black on face, ear-coverts, supercilium, lower back and rump, and below; immature like female, incompletely described but paler overall, with broader greyish-white margins of remiges, more strongly barred underparts. Race *indochinensis* is larger and darker than nominate; *jabouillei* is even darker, with grey of underparts deeper and more uniform, and central rectrices black. VOICE. Whistled song of 6–7 notes in descending sequence, also nasal chuntering "uh'uh'uh'uh-ik"; in Myanmar, a loud, metallic 3-note descending call.
Habitat. Open forest, secondary growth, deciduous woodland (Thailand), pine (*Pinus*) forest, locally peatswamp-forest; sometimes in town gardens. From 300 m to 1500 m.
Food and Feeding. Eats insects, including caterpillars (Lepidoptera). Forages in canopy and middle storey, moving with slow, deliberate actions; may join mixed-species flocks.
Breeding. Generally Apr–May; Apr–Jul in Myanmar. Nest a saucer of fine twigs and roots, bound with cobwebs; usually high in tree. Eggs 2–3. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Fairly common in all parts of its range.
Bibliography. Bangs & Van Tyne (1931), Buckton *et al.* (1999), Chazee (1994), Deignan (1945), Delacour (1951a, 1951b), Delacour & Jabouille (1940), Eames & Ericson (1996), Eames & Robson (1992), Inskipp *et al.* (1996), King *et al.* (1975), Lekagul & Round (1991), Mayr (1951), Robson (2000), Round (1988, 2000a), Smythies (1986), Stepanyan (1995), Tordoff *et al.* (2000).



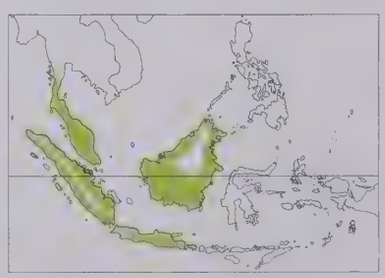
49. Black-winged Cuckoo-shrike

Coracina melaschistos

French: Échenilleur ardoisé **German**: Trauerraupenfänger **Spanish**: Oruguero Alinegro

Other common names: Dark-grey/Lesser Grey Cuckoo-shrike

Taxonomy. *Volvocivora melaschistos* Hodgson, 1836, Nepal.
Formerly sometimes considered conspecific with *C. fimbriata* or *C. melanoptera*. Relatively fine bill and colour of upperparts suggest that the three are possibly linked also with African *C. graueri* and Madagascan *C. cinerea*. Four subspecies recognized.
Subspecies and Distribution.
C. m. melaschistos (Hodgson, 1836) – N Pakistan (Murree Hills), and Himalayas E to NE India (upper Assam), S China (SE Xizang E to NW Yunnan) and W & N Myanmar; non-breeding S to N & NE India, SE Bangladesh (Chittagongs) and NW Thailand.
C. m. intermedia (Hume, 1877) – C, E & SE China (Gansu E to Hebei, S to Guangxi and Guangdong); non-breeding S Myanmar, S Thailand, S Vietnam, S China and Taiwan.
C. m. avensis (Blyth, 1852) – SW China (Sichuan, Yunnan, S Guizhou), S & E Myanmar, N Thailand, N Laos and N & C Vietnam; non-breeding also S to S Myanmar, S Thailand and S Indochina.
C. m. saturata (Swinhoe, 1870) – NE & C Vietnam (E Tonkin, N & C Annam) and Hainan I; non-breeding NW Thailand, S Laos, Cambodia and S Annam.



Descriptive notes. 19·5–24 cm; 35–42 g. A dark-looking cuckoo-shrike with relatively long, well-graduated tail. Male is overall dark iron-grey with slaty gloss, slightly paler slate on rump and uppertail-coverts, black around eye, on cheek and on ear-coverts; wings black, glossed green, lesser upperwing-coverts dark iron-grey; rectrices black, tipped white, central pair tipped grey; underparts paler towards abdomen and undertail-coverts; iris red-brown to dark brown; bill and legs black. Differs from *C. polioptera* in darker coloration, more graduated tail, no pale wing edgings, little or no white on primaries below. Female is sometimes very similar to male, but paler in general, often weakly barred dark and pale grey on underparts, including vent; often has broken white eyering and fine whitish streaks on cheeks. Juvenile is blackish-brown above and brownish-grey below, heavily scaled whitish all over, upperwing-coverts and tertials broadly tipped white; immature like female, but more strongly and extensively barred below, has pale tips of remiges and whitish tips of rectrices. Races differ in depth of coloration: *avensis* is paler than nominate; *intermedia* is even paler; *saturata* is darkest race, also small. VOICE. Song a series of 3 or more high-pitched, descending, downslurred whistles, preceded by few short, soft low notes; also raptor-like squealing; calls include a chatter like that of magpie (Corvidae).
Habitat. Deciduous forest, also broadleaf evergreen forest, open forest, edge, groves and bamboo jungle; in non-breeding season also in gardens, abandoned cultivation, open areas and woodland. Breeds at 300–2450 m; at lower elevations and in plains and valleys in non-breeding season.
Food and Feeding. Eats insects, mainly caterpillars (Lepidoptera) but also beetles (Coleoptera) and bugs (Hemiptera); also takes some fruit. Fairly active and conspicuous; normally forages singly or in pairs; often joins mixed-species parties. Gleans insects from leaves, usually in canopy but sometimes in undergrowth.
Breeding. Nests Apr–Jul. Nest a very small cup of twigs, rootlets, fibres, bark and lichens, bound with cobwebs, placed 3–8 m above ground on fork of tree branch. Eggs 2–4. No other information.
Movements. Marked seasonal movements, both altitudinal and latitudinal. Post-breeding descent from mountains to plains and valleys within breeding range, also migration to S. Migrants occur in breeding areas from late Mar to Oct. Nominate race associates with *intermedia* and *avensis* in non-breeding season; *intermedia* known to migrate through Yunnan (S China), and spends winter months alongside *avensis*, sometimes also with *saturata*, in SE Asia.
Status and Conservation. Not globally threatened. Very rare and local in Pakistan, frequent in Nepal, locally fairly common in India, and common in Bhutan; local in Bangladesh. Fairly common resident in SE Asia, where also locally common non-breeding visitor. Uncommon to locally common in China. Occurs in several protected area, including e.g. Royal Chitwan National Park, in Nepal, and Kaeng Krachan National Park, in Thailand.
Bibliography. 50. Lesser Cuckoo-shrike

Coracina fimbriata

French: Échenilleur frangé **German**: Zwergraupenfänger **Spanish**: Oruguero Menor

Taxonomy. *Ceblepyris fimbriatus* Temminck, 1824, Java.
Was in the past sometimes considered conspecific variously with *C. polioptera*, *C. melaschistos* and *C. melanoptera*. Relatively fine bill and colour of upperparts suggest possible link also with African *C. graueri* and Madagascan *C. cinerea*. Five subspecies recognized.
Subspecies and Distribution.
C. f. neglecta (Hume, 1877) – S Myanmar and S Thailand.
C. f. culminata (Hay, 1845) – Peninsular Malaysia.
C. f. schierbrandi (Pelzeln, 1865) – Sumatra and Borneo.
C. f. compta (Richmond, 1903) – Simeulue and Siberut (off W Sumatra).
C. f. fimbriata (Temminck, 1824) – Java and Bali.

Descriptive notes. 19–20·5 cm; 28–30 g. A small, short-tailed cuckoo-shrike with a rather fine bill. Male of nominate race has crown and upperparts dark slaty grey, being paler on rump and uppertail-coverts; lores and ear-coverts darker; wings black with glossy feather margins, lesser upperwing-coverts edged slaty grey; rectrices black, tipped greyish or white; throat and underparts, including underwing-coverts, dark slaty grey, becoming progressively paler towards abdomen and undertail-coverts; iris brown to red-brown; bill and legs are black. Differs from *C. melaschistos* in smaller size, less graduated

tail with less white at tips; from *C. polioptera* in lack of pale wing edgings. Female is paler grey above, ear-coverts and supercilium scaled dusky and whitish, white broken eyering, wings dark grey, wing-coverts edged pale greyish, remiges edged and tipped white, whitish patch on inner webs of some primaries and secondaries, greyish-white underparts barred dusky black. Juvenile not fully described; immature like female but paler, with variable barring on rump and uppertail-coverts, young female with reduced white on inner webs of primaries and secondaries. Races differ in size and in depth of coloration: *compta* is smaller than nominate, head less black; *culminata* is smaller and slightly less dark than previous; *schierbrandi* is same size as last, but darker; *neglecta* is largest and palest race. VOICE. Song a repeated, loud "whit-it-it-chui-choi" and so on; also has rapid series of "whit" notes and, when alarmed, a squeaky, nasal, repeated "wherrrh" and high "whit-weei".

Habitat. Forest, secondary growth, peatswamp-forest, farmland; lowlands to 1000 m, occasionally to 1500 m.

Food and Feeding. Food mainly insects, including caterpillars (Lepidoptera), flies (Diptera), beetles (Coleoptera), grasshoppers (Orthoptera); also flower spiders (Araneae), and some fruit and seeds taken. Forages in canopy; joins mixed-species flocks.

Breeding. Dependent juveniles in May and Jul in Peninsular Malaysia. Nest a small, neat cup placed on horizontal tree branch. Eggs 2. No other information.

Movements. None recorded.

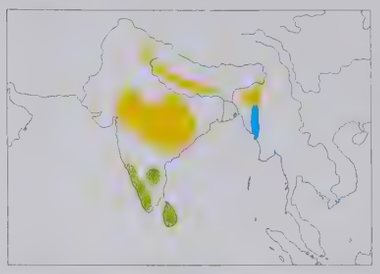
Status and Conservation. Not globally threatened. Generally uncommon. Reasonably common in S Thailand and Peninsular Malaysia, but rare in Singapore; rather scarce and local in Greater Sundas. Regarded as "Near-threatened" in Malay Peninsula as a result of destruction of forest habitat. Occurs in a few protected areas, including Taman Negara National Park, in Peninsular Malaysia, Danum Valley Conservation Area, in Borneo, and Gunung Gede-Pangrango National Park, in Java and Bali.

Bibliography. Andrew (1985), van Balen (1999), Davison (1995), Delacour (1951b), Hawa (1985), Hellebrekers & Hoogerwerf (1967), Inskipp *et al.* (1996), Jeyarajasingam & Pearson (1999), King *et al.* (1975), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Medway & Wells (1976), Robson (2000), Round (1988), Smythies (1986, 1999), Vowles & Vowles (1997), Wells (1990a, 2005).

51. Black-headed Cuckoo-shrike

Coracina melanoptera

French: Échenilleur à tête noire **Spanish**: Oruguero Cabecinegro
German: Schwarzkopf-Raupenfänger
Other common names: Large Grey Cuckoo-shrike



Taxonomy. *Ceblepyris melanoptera* Rüppell, 1839, New Holland?; error = Bhadwar, Kangra District, Punjab, India.

Type specimen not correctly described until 1951; species was formerly referred to as *C. sykesi*. Was in the past sometimes considered conspecific with *C. melaschistos* or *C. fimbriata*. Relatively fine bill and colour of upperparts suggest that the three are possibly linked also with African *C. graueri* and Madagascan *C. cinerea*. Two subspecies recognized.

Subspecies and Distribution.

C. m. melanoptera (Rüppell, 1839) – NW India (Himachal Pradesh, N Uttar Pradesh).

C. m. sykesi (Strickland, 1844) – S Nepal, India (E Rajasthan, Gujarat and NC Uttar Pradesh E to Assam, Nagaland and Manipur, S to Kerala and Tamil Nadu), Bangladesh and Sri Lanka; non-breeding E to W & SW Myanmar.

Descriptive notes. 19–20 cm; 24–36 g. Male nominate race has dark slate-grey head, neck and upper breast; mantle and rest of upperparts and underparts pale grey, becoming white on belly, vent and undertail-coverts; wings darker grey than mantle, broad pale fringes of upperwing-coverts and tertials; remiges black, edged whitish-grey, with white patch on inner webs of primaries; rectrices black, broadly tipped white, central pair grey; iris dark red-brown; bill and legs black. Female has whitish supercilium, upperparts slightly brownish-grey, back and rump lightly barred dark grey, wings and tail as male but duller, underparts buffy white, widely barred dark brown. Juvenile is similar to female, but upperparts barred white, and tertials and upperwing-coverts have dark subterminal marks; immature like female. Race *sykesi* is smaller and paler than nominate, with shorter tail, abdomen mostly white. VOICE. Often silent. Song a series of clear, mellow, whistled notes, "twit-wit-wit-wee-twéé-twéé-twy-twy-twy", often followed by quick, repeated "pit-pit-pit"; also a series of loud, upslurred whistles, "kwée"; female emits chirp.

Habitat. Open forest, secondary growth, scrub-jungle and bamboo; also in gardens, orchards, hedgerows, and trees in towns and cities. Lowlands to 1650 m; sometimes to 2100 m (Himalayas).

Food and Feeding. Food mostly insects, especially caterpillars (Lepidoptera); also takes fruit such as *Lantana* berries and figs (*Ficus*). Forages singly, in pairs or in small parties; often joins mixed-species foraging flocks. Flies from tree to tree, examining foliage slowly and carefully, gleaning from leaves, twigs and branches. Prefers to forage in tall trees; rarely, descends to the ground, where it progresses with long hops, like a thrush (Turdidae).

Breeding. Jun–Sept in N India and Nepal, Jun–Aug in C India and Apr–May in S; Mar–May in Sri Lanka. Nest a saucer of dry grasses, lightly bound with cobwebs, placed 2–8 m above ground in fork of bare branch of large tree. Eggs 2–3; incubation by both sexes. No other information.

Movements. Resident and partial migrant. Seasonal movements in Nepal, where seen mainly in spring and summer. In N & C India, mainly a breeding visitor; occurs throughout year in SW & SE, but population augmented by migrants in winter. Apparently transient throughout N plains and peninsula; mainly non-breeding visitor to S India and S Bangladesh, and scarce winter visitor to W & SW Myanmar. Occurs in Nilgiri Hills mostly in winter months (Oct–Apr); marked passage recorded in Jun and Sept–Oct in Maharashtra and Karnataka. Resident in Sri Lanka.

Status and Conservation. Not globally threatened. Scarce in Nepal; locally fairly common in India; local in Bangladesh; uncommon and local in Sri Lanka. Occurs in several protected areas, e.g. Nagarhole National Park, in India.

Genus *CAMPOCHAERA* Sharpe, 1878

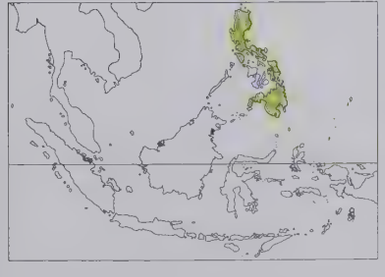
52. Golden Cuckoo-shrike

Campochaera sloetii

French: Échenilleur doré **German**: Goldraupenfänger **Spanish**: Oruguero Dorado
Other common names: Orange Cuckoo-shrike

Taxonomy. *Campephaga sloetii* Schlegel, 1866, Seleh, south-west cape of the Vogelkop, New Guinea.
Two subspecies recognized.
Subspecies and Distribution.
C. s. sloetii (Schlegel, 1866) – Arfak Mts (foothills) and N New Guinea lowlands (E to Wewak area).
C. s. flaviceps Salvadori, 1880 – S New Guinea lowlands from R Mimika E to Moroka, and foothills of Owen Stanley Range.

Descriptive notes. 20 cm; 36–46 g. A small cuckoo-shrike with small bill; striking plumage, dominated by golden-yellow, unique in family. Male nominate race has crown grey; base of forehead, lores and ear-coverts to throat and upper breast black, glossed greenish, black area separated from crown and hindneck by white band; upperparts predominantly golden-yellow, slightly more olive on scapulars, brighter from lower back to uppertail-coverts; upperwing-coverts black, glossed greenish, medians narrowly tipped white, greaters broadly edged white; primary coverts and remiges black, tertials edged white; rectrices black, tipped white, white broadest on outermost; underparts bright golden-yellow, axillaries and underwing-coverts white; iris dark brown; bill and legs black. Female is less brilliant yellow than male, has mantle olive-tinged, black on head and breast replaced by grey, but feathers around eye black, grey of crown washed yellow. Juvenile undescribed; immature like female, but grey of head replaced by yellow, with grey patch only on upper breast. Race *flaviceps* differs from nominate in having crown more greenish, and overall coloration slightly more olive-yellow. Voice. Noisy. Male has rapid, bubbling, repeated "chirrapa", often with upslurred note added, as "chrripaéé" or "wírrápáhee"; often 1–2 pairs of downslurred and upslurred notes added, and female may make chipping or chuckling notes before male's call. Duetting displays frequent, female giving upslurred or downslurred notes during last 2–3 notes of male's call. Birds from NW of range lack the musical slurs, start the call with explosive clicking.
Habitat. Primary forest and forest edge; mainly in hill forest, locally also in lowlands near hills. Occurs locally up to 1100 m.
Food and Feeding. Eats mostly fruit; insects also recorded. Occurs in pairs or small parties in upper canopy and outer foliage. Forages actively and noisily; obtains food by gleaning and by "flycatcher-gleaning".
Breeding. No information. Thought to breed during rainy season, Nov–Mar.
Movements. None recorded.
Status and Conservation. Not globally threatened. Known distribution rather patchy; locally common. Not well known.
Bibliography. Andrew (1992), Beehler *et al.* (1986), Bell (1982b), Coates (1990, 2001), Diamond (1972), Diamond & Terborgh (1968), Gregory (1995), Mack *et al.* (2000), Rand (1942), Rand & Gilliard (1967), Ripley (1964).



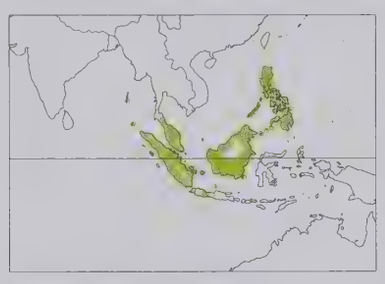
Genus *LALAGE* Boie, 1826

53. Black-and-white Triller

Lalage melanoleuca

French: Échenilleur noir et blanc **German**: Philippinenlalage **Spanish**: Oruguero Blanquinegro

Taxonomy. *Pseudolalage melanoleuca* Blyth, 1861, Luzon, Philippines.
Two subspecies recognized.
Subspecies and Distribution.
L. m. melanoleuca (Blyth, 1861) – N Philippines (Luzon, Mindoro, Semirara).
L. m. minor (Steere, 1890) – EC & S Philippines (Samar, Leyte, Mindanao).



Descriptive notes. 21–22 cm; 42–48·5 g. Male nominate race is glossy greenish-black above, centre of back grey, rump and uppertail-coverts white; scapulars and most upperwing-coverts as mantle, innermost median coverts pure white, innermost greaters have white outer webs; remiges greenish-black, secondaries edged white (white edges, together with white on coverts, form white line along closed wing); rectrices greenish-black, narrowly tipped white, white broadest on outermost pair; entirely white below, including underwing-coverts; iris dark brown; bill and legs black to grey-black. Distinguished from *L. nigra* and *Pericrocotus divaricatus* by relatively large size, white lower back and rump, lack of white supercilium. Female is like male but grey replaces black on upperparts, and has grey-barred underparts. Juvenile and immature undescribed. Race *minor* is smaller than nominate, underparts of female darker grey. Voice. A loud series of repeated "cha-chi" notes or longer "ka-choo" notes, each series lasting for 3–12 seconds or longer; also staccato "chi chi chi chi".
Habitat. Canopy of forest and forest edge, below 1000 m.
Food and Feeding. No information on diet; presumably insectivorous. Occurs singly, in groups or with mixed-species foraging flocks.
Breeding. Juveniles in May on Luzon and Mindoro. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Not well known; currently regarded as uncommon to fairly common. Occurs in Quezon National Park, on Luzon.
Bibliography. Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), duPont (1971), Gilliard (1950), Goodman & Gonzales (1990), Inskipp *et al.* (1996), Kennedy *et al.* (2000), McGregor (1905), Pardo & Gogorza y González (1997), Rabor (1977), Rand & Rabor (1960).

54. Pied Triller

Lalage nigra

French: Échenilleur térat **German**: Weißstirnlalage **Spanish**: Oruguero Pío

Taxonomy. *Turdus niger* J. R. Forster, 1781, East Indies = Manila, Philippines.
May form a superspecies with *L. leucopygialis*, and the two are often considered conspecific; nevertheless, on basis of plumage characters, present species appears to be closer to *L. sueurii* than to *L. leucopygialis*. It has been suggested that present species may form a superspecies with *L. sueurii*, or that the two might even be conspecific; in such scenarios, merging of *L. leucopygialis* into present species would be inappropiate, due to resultant sympatry with *L. sueurii* in Sulawesi; indeed, present species and *L. sueurii* may be sympatric in C Java. In past, type specimen of present species was reckoned to have come from Singapore; under that arrangement, the populations of mainland SE Asia, Sumatra and Java now labelled as race *striga* constituted the nominate race, while the populations of Borneo and Philippines now considered to form the nominate were allotted race *chilensis*. Three subspecies currently recognized.
Subspecies and Distribution.
L. n. davisoni Kloss, 1926 – S Andaman Is, and C Nicobar Is (Camorta, Katchall, Trinkat).
L. n. striga (Horsfield, 1821) – S Thailand, Peninsular Malaysia, Singapore, Sumatra (including Nias I), Bangka, Belitung and W Java (including Karimunjawa Is).
L. n. nigra (J. R. Forster, 1781) – Borneo and adjacent islands, and Philippines.

Descriptive notes. 16·5–18 cm (*striga*, *nigra*), 13·5–14 cm (*davisoni*); 20–31 g. Male nominate race has forehead, crown, nape, mantle and scapulars glossy black; broad white supercilium, black lores and streak through eye to nape; rest of head side white; back to uppertail-coverts dove-grey, uppertail-coverts slightly darker and tipped white; alula, lesser upperwing-coverts and primary coverts black, median and greater coverts white; remiges black, secondaries broadly fringed white, inner primaries tipped white; rectrices black, tipped white, outermost white except for black basal half of inner web; throat and underparts, including axillaries and underwing-coverts, white, breast washed pale grey; iris dark brown; bill and legs black. Differs from *L. leucopygialis* in having grey, not white, rump and uppertail-coverts. Female has black of plumage replaced by greyish-brown, grey of back to uppertail-coverts tinged ashy, white edges and tips of upperwing-coverts and remiges narrower than on male, innermost rectrix mostly greyish-brown, underparts washed buffish with narrow dark scales. Juvenile is like female, but upperparts browner, with fine buff-white feather fringes, primaries more broadly tipped white, innermost rectrix entirely greyish-brown, side of throat, breast and undertail-coverts have blackish shaft streaks; immature resembles adult female. Races differ mainly in plumage of female: *striga* female has browner cap and mantle than nominate; *davisoni* is smaller, female greyer on upperparts. Voice. Has rather nasal chuckles, e.g. "chaka-chevu", "whéék-chuk" and similar; rattling "wheek chechechecheche-chuk", also "kew kew" followed by 2–8 "kyhek" or "chack" notes on descending scale; whining "whier" contact call.
Habitat. Open woodland, forest edge, farmland, roadsides and gardens in villages and towns, cultivation, plantations, coastal scrub, mangroves and casuarina (*Casuarina*) groves. Favours large trees, especially those with divided leaves, where these present. Lowlands to 1000 m; once to 1550 m in Peninsular Malaysia.
Food and Feeding. Food arthropods, mainly caterpillars (Lepidoptera) and "hard insects"; some fruit, mostly small berries (e.g. of euphorbs such as *Breynia*), also taken. Solitary, in pairs or in small flocks. Forages at all levels in trees, less often in bushes and hedgerows; takes prey mostly from outer foliage, but also from dead or leafless branches. Items usually captured in an upward hop from a perch to a surface; snatches flushed insects, and sometimes makes sallies of several metres. Occasionally hunts on ground, taking prey from short-grass areas.
Breeding. Breeds May in Nicobars, Feb–Aug in Malay Peninsula, Feb–Apr and Jun–Aug in Sumatra, Jun in Borneo and May–Jun in Philippines; two broods recorded in Singapore. Nest an open cup of grass, fibre, casuarina needles and the like, bound externally with cobwebs, placed on exposed but inaccessible, lichen-covered, horizontal branch 3–9 m above ground. Eggs 2–3; no information on incubation and fledging periods; young fed by both parents.
Movements. Primarily resident. Recorded seasonal changes in abundance in Singapore are suggestive of migration; local dispersal possible elsewhere in Malay Peninsula, but more observations needed.
Status and Conservation. Not globally threatened. In Peninsular Malaysia, regular and common in S and on W coastal plain, but local and uncommon to rare elsewhere; locally common to uncommon in S Thailand. Fairly common in Greater Sundas, but absent from Bali. Uncommon to rare on Nicobar Is.
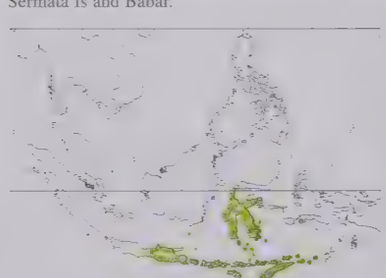
Bibliography. Round (1991), MacKinnon & Phillipps (1993), Madoc (1976), van Marle & Voous (1988), Mayr & Ripley (1941), McClure (1998), Medway & Wells (1976), Mees (1986, 1996), Rabor (1977), Rasmussen & Anderton (2005), Ripley (1982), Robson (2000), Round (1988), Sibley & Monroe (1990), Smythies (1999), Stresemann (1952), Wardill (1995), Wells (2005), White & Bruce (1986).

55. White-rumped Triller

Lalage leucopygialis

French: Échenilleur de Walden **German**: Sulawesilalage **Spanish**: Oruguero de Walden
Other common names: Sulawesi Triller

Taxonomy. *Lalage leucopygialis* Walden, 1872, Menado, Sulawesi.
May form a superspecies with *L. nigra*, and the two are often considered conspecific; nevertheless, on basis of plumage characters, *L. nigra* appears to be closer to *L. sueurii* than to present species. Sympatry of present species with *L. sueurii* in Sulawesi means that these two can not satisfactorily belong to the same superspecies. Monotypic.
Distribution. Sulawesi (including islands of Manadotua, Bangka, Muna and Buton), Banggai Is and Sula Is (Taliabu, Sanana).



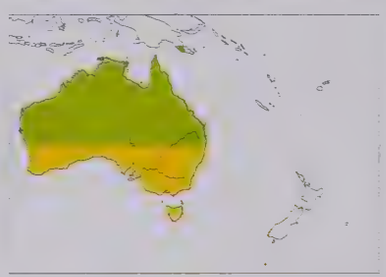
Descriptive notes. 19 cm. Male has forehead and crown to mantle and scapulars very dark grey to blackish, glossed greenish; broad white supercilium, blackish lores and streak through eye; eyelids and rest of head side white; lower back to uppertail-coverts pale grey, becoming white on rump; alula and lesser upperwing-coverts glossy blue-black, greater and median coverts blackish, broadly margined white; primary coverts black; remiges black, primaries narrowly tipped white, secondaries and tertials margined white; rectrices blackish, outermost two tipped white; throat and underparts pure white, tiny dusky bars on foreneck and throat, grey thighs; iris dark brown; bill and legs black. Differs from *L. nigra* in having white, not pale grey, rump. Female has black crown, paler and much greyer upperparts (where male dark grey to black), white edges and tips of upperwing-coverts and remiges less prominent than on male, underparts washed buffish with narrow dark scales. Juvenile is like female, but with rusty feather tips on upperparts, supercilium tinged rusty, all rectrices brown with white tips, underparts buffy white, dusky bars on flanks; immature undescribed. Voice. A loud, swelling series of rapid, hard, clear, chattering notes, duration 1·5 seconds, repeated at c. 3-second intervals.
Habitat. Forest edge, heavily disturbed forest, secondary forest, open woodland, farmland, gardens, lightly wooded cultivation and mangroves. Sea-level to 1000 m.
Food and Feeding. Diet not recorded; presumably similar to that of *L. nigra*. Occurs singly, in pairs or in small groups; forages in crowns of large and small trees, also in middle storey; also forages near ground in mangroves.
Breeding. Breeds in May. Nest a compact open cup, not properly described but probably similar to that of *L. nigra*; one was placed on horizontal branch 18 m above ground. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Widely distributed and locally common on Sulawesi; common on Taliabu. Not well known.
Bibliography. Andrew (1992), Catterall (1997), Coates & Bishop (1997), Dickinson & Dekker (2002a), Escott & Holmes (1980), Holmes & Phillipps (1996), Inskipp *et al.* (1996), Mayr & Ripley (1941), Stresemann (1939, 1952), Watling (1983a), Wells (2005), White & Bruce (1986).

56. White-shouldered Triller

Lalage sueurii

French: Échenilleur de Lesueur **German**: Weißschulterlalage **Spanish**: Oruguero de Lesueur
Other common names: Sueur's Triller

Taxonomy. *Turdus Suerii* [sic] Vieillot, 1818, New Holland; error = Timor.
May form a superspecies with *L. tricolor*, and the two are sometimes considered conspecific. It has been suggested that present species may form a superspecies with *L. nigra*, or that the two might even be conspecific, although they may be sympatric in C Java. Sympatry with *L. leucopygialis* in Sulawesi means that these two taxa can not satisfactorily belong to the same superspecies. Monotypic.
Distribution. C & E Java, Bali, Salembu Besar, NC & S Sulawesi (including Salayar, Buton and Tukangbesi), islands in Flores Sea (Tanahjampea, Kalao, Bonerate, Kalaotoa, Madu), and Lesser Sundas (Lombok E to Alor, S to Sumba, Savu, Roti and Timor) E to Wetar, Romang, Kisar, Moa, Sermata Is and Babar.



Descriptive notes. 17–18 cm. Male has top of head and upperparts glossy greenish-black; narrow white supercilium (sometimes poorly marked) bordered below by black line from base of bill to nape; lower back, rump and uppertail-coverts light grey, uppertail-coverts tipped whitish; lesser and median upperwing-coverts white with black shaft streaks (large "shoulder patch"), greater coverts black, edged white; remiges black, secondaries and tertials edged white; rectrices black, narrowly tipped white, central pair narrowly edged white; cheeks, ear-coverts, neck side, throat and entire underparts, including underwing-coverts and axillaries, pure white; iris dark brown; bill grey to black; legs black. Differs from *L. leucopygialis* in having greener dorsal gloss and white lesser upperwing-coverts; from *L. tricolor* in having white supercilium; from *L. nigra* in larger size, narrower supercilium, more white in wing, grey on lower back. Female has black of upperparts, wings and tail replaced by rufous-brown, supercilium washed rufous, pale buffish edges of upperwing-coverts and remiges, buffy white below, breast and flanks narrowly and indistinctly barred dusky, thighs greyish. Juvenile is like female, but lower back light brown, underparts with brownish shaft streaks; immature also like female, but not fully described. Voice. Harsh, rattling series of rapid, staccato notes that almost run together; song a series of c. 12 clear, rapidly repeated, musical notes.
Habitat. Woodland, savanna, open forest, scrub, overgrown or lightly wooded cultivation (including rice fields), also gardens and areas near human habitations; occasionally in swamps. Also mangroves in Lesser Sundas (Sumba). Lowlands to 1630 m. Generally prefers drier habitats than those favoured by *L. nigra*.
Food and Feeding. Diet not recorded; presumably insects. Perches in isolated trees and on stumps and fence posts; forages on the ground in short grass and on bare areas.
Breeding. Breeds in Apr–May in Lesser Sundas. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Current status not well known. Regarded as common in C Sulawesi, and expanding N, in 1980s; fairly common in E Java and Bali in 1990s; common on Tanahjampea. Widespread and locally common in Lesser Sundas, including on some of the small islands. Occurs in several protected areas in Java and Bali, e.g. Bali Barat National Park.
Bibliography. Andrew & Holmes (1990), van Balen (1999), Baltzer (1990), Bruce (1987), Coates & Bishop (1997), Escott & Holmes (1980), Fraser & Henson (1996), Immelmann (1962), Johnstone & Jepson (1996), Johnstone *et al.* (1996), Jones *et al.* (1994), Mackay (1976), MacKinnon & Phillipps (1993), Mayr & Ripley (1941), Mees (1986, 1996), Schodde & Mason (1999), Trainor (2002a), Wardill (1995), Watling (1983a), White & Bruce (1986).

57. White-winged Triller

Lalage tricolor

French: Échenilleur tricolore **German**: Weißflügellalage **Spanish**: Oruguero Tricolor
Other common names: Australian/Jardine Triller, White-shouldered Caterpillar-eater

Taxonomy. *Ceblepyris tricolor* Swainson, 1825, Sydney, New South Wales, Australia.
May form a superspecies with *L. sueurii*, and the two are sometimes considered conspecific. Monotypic.
Distribution. Australia, including Melville I and Tasmania; also SE New Guinea (Port Moresby area).

Descriptive notes. 15·5–18·5 cm; 26–31·5 g. Male breeding has top of head down to level of eye, and upperparts, upperwings and tail glossy greenish-black; lower back, rump and uppertail-coverts light grey; upperwing-coverts pure white, greater coverts with black inner webs; secondaries edged white, outer pair of rectrices broadly tipped white; throat and underparts, including underwing-coverts and axillaries, pure white; iris dark brown; bill and legs black. Differs from *L. sueurii* in lacking white supercilium; from *L. leucomela* also in prominent white "shoulder patch", entirely white underparts. Male "eclipse" plumage assumed after breeding, when head and mantle become brown (as on female), underparts whitish, and rectrices edged white. Female has black areas of breeding male replaced by brown, feathers of rump and uppertail-coverts edged pale buffy, narrow buff-white supercilium, ear-coverts indistinctly patterned brown and white, upperwing-coverts and secondaries brown with broad sandy-buff edges, brown tail feathers tipped whitish; underparts pale buff, obscure dusky barring on side of breast. Juvenile has head and nape freckled brown and white, buff edges of wing feathers, brown streaks on white underparts; immature like female, young male with more buff on head, mantle, upperwing-coverts and breast than eclipse male. Voice. Territorial song a clear, sustained, variable sequence of notes, "chiff-chiff-chiff-joey-joey-joey", ending in canary-like trill.
Habitat. Wide range of lightly timbered habitats with sparse open shrub layer and grassy ground cover, particularly dry, open eucalypt (*Eucalyptus*) woodland and forest, mallee, native pine and acacia (*Acacia*) scrub, spinifex and sparsely wooded farmland; sometimes in suburban areas. Rarely in heavily forested areas, except where clearing has taken place, at forest edges and in riverine forest. On migration, occurs in open country with trees, and sometimes coastal casuarina (*Casuarina*) groves. Requires bare ground or short grass for foraging; attracted to burnt ground, mown grass, and ground where crops have been harvested.
Food and Feeding. Eats insects, including caterpillars (Lepidoptera), grasshoppers and crickets (Acrididae, Tettigoniidae, Gryllidae), cockroaches (Blattodea), mantids (Mantodea), winged termites (Isoptera), ants (Formicidae), phasmids (Phasmatodea), bugs (Hemiptera, including Cicadidae and Cicadellidae), beetles (including families Scarabaeidae, Chrysomelidae, Apionidae, Circulidae), horseflies (Tabanidae), ichneumons (Ichneumonidae) and bees (Apidae); also takes spiders (Arachnida). Fruit and seeds also recorded; sometimes feeds on nectar of *Callistemon* (Myrtaceae). Forages singly or in pairs, sometimes (especially during non-breeding season) in flocks; occasionally joins mixed-species flocks. Often forages on the ground; sometimes feeds by gleaning among foliage and on trunks and branches of trees and bushes, and by sallying and sally-striking; sometimes hovers close to ground to sally-pounce on insects.
Breeding. Season Jun–Mar in Australia and Sept–Dec in New Guinea; also nests after rains in arid regions of Australia, where may nest twice during extended seasons of abundance. Usually monogamous, but there is one record of polygyny. Often nests in loose colonies. Nest built by both sexes, a small, frail, neat saucer of dry grass, bark, rootlets, stems, tendrils, plant down, moss, wool and horsehair, lined with fine grass and rootlets and bound with cobwebs, placed 1–12 m or more above ground on horizontal or slightly sloping fork of thin branch of tree or shrub, with preference for rough-barked trees; often builds within mistletoe (Loranthaceae) clump or below clump of leaves. Eggs 1–3, usually 2; incubation by both sexes, period c. 14 days; chicks fed and brooded by both parents for 8 days, thereafter by female only, nestling period 12 days; fledglings fed by female alone.
Movements. Partial migrant, largely vacating mainland Australia S of 29ºS in autumn (Feb–Apr) and moving to N Australia, returning S (mainly in Aug–Sept) to breed; a few individuals occasionally reach SE New Guinea (only one record from Torres Strait); return movements S in Australia recorded Aug–Oct. Also appears irregularly in many of the more arid districts of Australia, depending on rains; can be common in desert areas in good seasons. Migrates in flocks of 20–60 birds, but arrivals noted singly or in small parties. Sea crossings sometimes ship-assisted. Vagrants recorded on Lord Howe I and in New Zealand.
Status and Conservation. Not globally threatened. Widespread and sometimes locally common. Estimated densities 0·01–1 birds/ha. Sometimes locally common in New Guinea.
Bibliography. Beehler *et al.* (1986), Bell (1965, 1969), Beruldsen (1980), Blakers *et al.* (1984), Brooker & Brooker (1987), Brooker *et al.* (1979), Christidis & Boles (1994), Coates (1990), Hall (1974), Higgins *et al.* (2005), Hobbs (1986), Immelmann (1966), Keast (1958), Larkins (1983), MacDonald (1988), Mayr & Rand (1937), Morcombe (2000), Pizzey (1980), Rand & Gilliard (1967), Schodde & Mason (1999), Serventy & Whittell (1976), Simpson & Day (1994), Trounson & Trounson (1987), White & Bruce (1986).

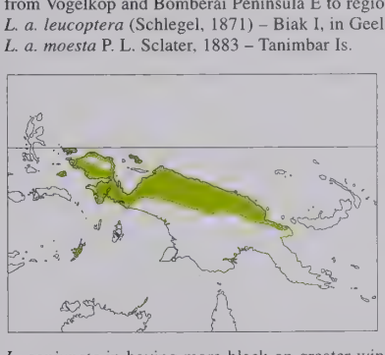
58. **Rufous-bellied Triller**

Lalage aurea

French: Échenilleur orangé **German**: Rotbauchlalage **Spanish**: Oruguero Ventrirrufo
Other common names: Red-bellied/Moluccan/Black-backed Triller

Taxonomy. *Ceblepyris aureus* Temminck, 1825, Timor; error = Ternate, off west Halmahera.
Forms a superspecies with *L. atrovirens*, *L. leucomela* and *L. conjuncta*. Monotypic.
Distribution. N Moluccas: Morotai, Halmahera, Ternate, Kayoa, Kasiruta, Bacan and Obi.



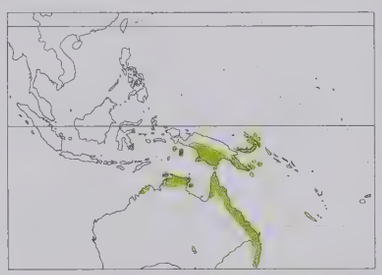
Descriptive notes. 20 cm. Male has upperparts glossy blue-black; narrow white supercilium and broken eyering, black line from base of bill through eye, white ear-coverts (white extending a little way down side of neck), white cheeks and chin; median upperwing-coverts white (forming bar across closed wing), greater coverts black at base and white towards tip (forming second wingbar); primary coverts and remiges black with white inner webs, secondaries broadly margined white (forming longitudinal wingbar); tail black, outer two feather pairs conspicuously tipped white; throat and underparts rufous, paler on throat, thighs black and white; underwing-coverts pure white; iris dark brown; bill black, legs dark grey. Differs from all congeners in having uniformly chestnut underparts. Female has upperparts slaty grey, glossed blue-black; otherwise as male, but cheeks and ear-coverts mottled white and grey, white chin spot indistinct, white tip of penultimate rectrix indistinct. Juvenile male is similar to adult female, but has white cheeks, supercilium tinged rusty and continuing to base of bill, feathers of rump and uppertail-coverts, and of much of upperparts, edged rusty, primary coverts tipped white, chin rufous and uniform with underparts, breast with dark brown spots; immature similar to adult female, but not properly described. Voice. A series of 7 staccato, piping notes, the sixth occasionally given as unpiped disyllable.
Habitat. Primary and selectively logged forest, forest edge, open secondary forest, scrub, coastal woodland and mangroves; from sea-level to at least 450 m (Halmahera).
Food and Feeding. Insectivorous; details of food items not recorded. Forages in middle storey to upper canopy, including in trees with little foliage.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Northern Maluku EBA. Moderately common on Halmahera. This species' numbers must have been reduced by forest destruction, but its ability to occupy selectively logged forest suggests that it may not have suffered so serious a reduction as have some other forest species.
Bibliography. Andrew (1992), Coates & Bishop (1997), Hartert (1903), Inskipp *et al.* (1996), Lambert (1994), Mayr & Ripley (1941), Michaux (1998), Strange (2001), Sujatnika *et al.* (1995), White & Bruce (1986).

59. **Black-browed Triller**

Lalage atrovirens

French: Échenilleur papou **German**: Papualalage **Spanish**: Oruguero Cejinegro
Other common names: White-rumped Triller(!); White-browed/Tanimbar Triller (*moesta*)

Taxonomy. *Campephaga (Lalage) atrovirens* G. R. Gray, 1862, Misool, off west New Guinea.
Forms a superspecies with *L. aurea*, *L. leucomela* and *L. conjuncta*. Distinctive race *moesta* sometimes regarded as a separate species, and may be closer to *L. aurea* than to present species; in the absence of vocal and behavioural data, however, it is probably better retained here. Three subspecies recognized.
Subspecies and Distribution.
L. a. atrovirens (G. R. Gray, 1862) – W Papuan Is (Waigeo, Salawati, Misool), and N New Guinea from Vogelkop and Bomberai Peninsula E to region of R Sepik and R Ramu.
L. a. leucoptera (Schlegel, 1871) – Biak I, in Geelvink Bay.
L. a. moesta P. L. Sclater, 1883 – Tanimbar Is.



Descriptive notes. 18–19 cm; 31·5 g. Male nominate race has forehead to nape, lores, upper ear-coverts and upperparts black, glossed blue-green; rump white, uppertail-coverts barred black and white; upperwing-coverts black, median and greater coverts broadly tipped white, innermost greaters also margined white; alula, primary coverts and remiges black, tertials broadly edged white; rectrices black, edged greenish, outermost tipped white; lower ear-coverts, cheeks, neck side, throat and entire underparts, including axillaries and underwing-coverts, pure white; iris dark brown; bill black, legs dark grey. Differs from *L. conjuncta* in having more black on greater wing-coverts, no chestnut on lower underparts, no black on thighs; from *L. sueurii* in having less white in wing, no white supercilium. Female is like male, but duller, upperparts dark grey to black, with less gloss, chin and throat white, breast and flanks finely barred black. Juvenile undescribed; immature resembles female. Race *leucoptera* has more white in wing than nominate, female lacks barring on underparts; *moesta* is distinctive, has white supercilium from forehead to eye (often also indicated behind eye), and female resembles male in colour of upperparts and lack of breast and flank barring. Voice. One song comprises sweet, rapidly repeated upslurred "twee" whistles; also has a "see o seet weo", repeated five or six times. Pair-members countersing with sweet "tewhit tewheet wheetu"; also 5–7 notes "reminiscent of laughter".
Habitat. Forest, forest edge, low open forest, secondary growth, scrub, gardens, partly cleared areas, mangroves and sparse littoral woodland; more often in secondary or light forest, or at forest edges, than in primary or tall forest. Mostly lowlands, but in New Guinea locally to 1400 m.
Food and Feeding. Eats fruit and arthropods. Forages singly, in pairs or in small parties; sometimes recorded in mixed-species flocks. Forages in canopy and middle storey, especially at openings, taking small fruits and gleaning from leaves.
Breeding. Juvenile seen in mid-Jun in New Guinea. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Status not well known. Regarded as fairly common in New Guinea, and common in Tanimbar Is (Yamdena).
Bibliography. Andrew (1992), Beehler *et al.* (1986), Coates (1990), Coates & Bishop (1997), Diamond, J.M. (1972, 1985), Inskipp *et al.* (1996), Mack *et al.* (2000), Mayr & Ripley (1941), Mees (1965), Michaux (1998), Rand & Gilliard (1967), Ripley (1964), Strange (2001), White & Bruce (1986).

60. **Varied Triller**

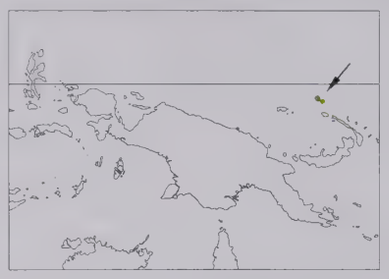
Lalage leucomela

French: Échenilleur varié **German**: Weißbrauenlalage **Spanish**: Oruguero Variable
Other common names: White-browed/Pied Triller(!)/Caterpillar-eater

Taxonomy. *Campephaga Leucomela* Vigors and Horsfield, 1827, south-east Queensland, Australia.
Forms a superspecies with *L. aurea*, *L. atrovirens* and *L. conjuncta*. Last-mentioned often treated as conspecific with present species, but plumage markedly distinct. Fifteen subspecies currently recognized.
Subspecies and Distribution.
L. l. keyensis Rothschild & Hartert, 1917 – Kai Is.
L. l. polygrammica (G. R. Gray, 1858) – Aru Is, and E & S New Guinea (E from Wau and Huon Gulf, S to R Mimika).
L. l. falsa Hartert, 1925 – S Bismarck Archipelago (Umboi, New Britain, Duke of York).
L. l. albidior (Hartert, 1924) – New Hanover.
L. l. karu (Lesson & Garnot, 1827) – New Ireland.
L. l. sumunae Salomonsen, 1964 – Djaul I, off W New Ireland.
L. l. tabarensis Mayr, 1955 – Tabar Is, off N New Ireland.
L. l. ottomeyeri Stresemann, 1933 – Lihir Is (S of Tabar Is).
L. l. triobriandi Mayr, 1936 – Triobriand Is, off E New Guinea.
L. l. obscurior Rothschild & Hartert, 1917 – D'Entrecasteaux Archipelago (Goodenough, Fergusson, Normanby).
L. l. pallescens Rothschild & Hartert, 1917 – Louisiade Archipelago (Misima, Renard, Tagula).
L. l. macrura Schodde, 1989 – NE Western Australia (Kimberleys).
L. l. rufiventris (G. R. Gray, 1846) – N Northern Territory (Arnhem Land) and Melville I, in N Australia.
L. l. yorki Mathews, 1912 – coastal N Queensland (Cape York Peninsula) and islands in Torres Strait; also coastal Trans-Fly region of SC New Guinea.
L. l. leucomela (Vigors & Horsfield, 1827) – coastal E Queensland S to NE New South Wales (Newcastle area).

Descriptive notes. 17–19·5 cm; 24–37·5 g. Male nominate race has prominent white forehead and supercilium, black line through eye to nape, cheeks, ear-coverts and eyelids white; glossy greenish-black on crown and upperparts, rump grey, mottled black, uppertail-coverts grey; lesser upperwing-coverts as back, median coverts white with black bases, greaters black, tipped white (two distinct wingbars), alula and primary coverts black; remiges black, primaries narrowly edged white, secondaries and tertials broadly edged white; rectrices black, tipped white, white broader on outer feathers; throat and underparts greyish-white, finely barred dark (variable), thighs grey, vent and undertail-coverts orange-buff; underwing-coverts and axillaries white, indistinctly barred light grey; iris dark brown; bill black, legs grey. Distinguished from *L. sueurii* and *L. tricolor* in having prominent white supercilium, distinct white wingbars, orange-buff undertail-coverts; from *L. conjuncta* mainly by white supercilium, grey (not white) rump, less white in wing, white (not chestnut) undertail-coverts; from *L. atrovirens* by prominent supercilium, rufous-buff undertail-coverts. Female is like male, but black areas replaced by dark ashy brown, supercilium mottled grey, rump and uppertail-coverts greyer brown with whitish feather fringes, greater upperwing-coverts broadly edged and tipped white, primary coverts tipped white; underparts fawn-buff, barred dusky blackish except on throat and belly, with vent and undertail-coverts as male, underwing-coverts washed fawn. Juvenile is like female, but barred on upperparts, streaked dusky on underparts; immature also like female, but somewhat browner overall, underparts paler buff with broken bars. Races differ in overall colours, rump colour and pattern, and degree of sexual dimorphism: *yorki* is black above, black-mottled grey on rump, unbarred white below, female dusky-grey above and greyish-white below; *rufiventris* is black above, mottle-barred black and grey on rump and uppertail-coverts, grey-white with dark barring below, female greyish-brown above and buff below; *macrura* resembles previous, but undertail-coverts less rich buff; *keyensis* resembles last, but male mottled grey and white on rump, female grey above; *polygrammica* male has vestigial supercilium, black rump with white mottles, strongly barred underparts, female mid-grey above, barred black and white on rump, more richly coloured below, with heavy barring; *falsa* male has ochraceous tinge below extending forwards to central lower breast; *albidior* is similar to previous, but whiter with less barring below; *karu* is also similar, but male differs in having greyer underparts with less extensive rufous, female in having greyer upperparts; *sumunae* male has no rufous on underparts, which have dark barring; *ottomeyeri* male has pure white underparts with virtually no rufous and almost no barring; *tabarensis* is like previous, but has broad white bars on rump and uppertail-coverts, broader supercilium; *obscurior* male is darkish above, rufous-buff on most of underparts; *triobriandi* has grey underparts, with rufous-buff only on undertail-coverts; *pallescens* is similar to last but paler below. Voice. Vocal, with loud, rolling, repeated "brreeer" or "cherwee" call; several individuals may call together to produce widespread chorus; also, repeated "drr-eea".
Habitat. Tropical and subtropical rainforest, monsoon forest, dense eucalypt (*Eucalyptus*) forest, gallery forest and forest edges, also secondary growth, woodland, dense savanna, thickets (e.g.

On following page: 61. St Matthias Triller (*Lalage conjuncta*).



Lantana in Australia) and mangroves; also occurs in gardens. Mainly lowlands, but locally to 1800 m in New Guinea.
Food and Feeding. Feeds on insects, including especially caterpillars (Lepidoptera), also grasshoppers (Orthoptera); fruit, berries and seeds also taken, and is particularly attracted to figs (*Ficus*). Forages mainly in canopy, in pairs or trios; inconspicuous, and seldom associates with other species except at fruiting fig trees. Insect food obtained by gleaning from leaves and twigs, sometimes by sallying, sally-hovering or flutter-chasing.
Breeding. Breeds Sept–Mar in Australia; Sept–Nov in New Guinea, but fledged young also seen Jun–Jul. Nest a very small, shallow cup of dry grass, fine twigs, bark, vine tendrils, plant stalks and rootlets, bound with cobwebs and lined with lichen or rootlets, placed 1–20 m above ground on thin horizontal branch or fork, often among vine foliage. Lays 1 egg; incubation and fledging periods unknown; nestling fed by both parents.
Movements. Sedentary over most of range. In Australia some movement suggested in Queensland, to S coastal plains and adjacent islands, and in New South Wales reported as partially nomadic (probably involving local movements between habitats).
Status and Conservation. Not globally threatened. Fairly common in much of range. Common in Kai Is and fairly common throughout its range in New Guinea and nearby islands; population estimated to be 6 birds/10 ha in one New Guinea rainforest. Considered locally fairly common in N Australia, but rather rare in New South Wales; population densities of 0·08-2·8 birds/ha recorded in N Australia.
Bibliography. Beehler *et al.* (1986), Beruldsen (1980), Blakers *et al.* (1984), Christidis & Boles (1994), Coates (1990, 2001), Coates & Bishop (1997), Diamond (1972), Dutson (2005d), Hall (1974), Higgins *et al.* (2005), Keast (1958), Liddy (1990), Longmore (1978), MacDonald (1988), Mackay (1976), Mayr (1955), Mayr & Rand (1937), Mayr & Ripley (1941), Mees (1982), Morcombe (2000), Panetta (1980), Pizzey (1980), Rand (1942), Rand & Gilliard (1967), Rothschild (1917), Schodde & Mason (1999), White & Bruce (1986).

61. St Matthias Triller

Lalage conjuncta

French: Échenilleur des Saint-Matthias **Spanish**: Oruguero de San Matías
German: St. Matthias-Lalage
Other common names: Mussau Triller

Taxonomy. *Lalage conjuncta* Rothschild and Hartert, 1924, St Matthias Island (= Mussau Island), Bismarck Archipelago. Forms a superspecies with *L. aurea*, *L. atrovirens* and *L. leucomela*. Often treated as conspecific with last-mentioned, but plumage distinct. Monotypic.
Distribution. Mussau I, in St Matthias Group (Bismarck Archipelago).

Descriptive notes. 17–18 cm. Male is black on top of head (including lores and down to below eye) and upperparts; rump white, uppertail-coverts barred black and white; lesser and median upperwing-coverts as back, greater coverts white, innermost greaters with black inner webs; alula and primary coverts black; remiges black, inner edge of primaries white, outer edge of secondaries and tertials white; tail black, outer feathers tipped white; cheeks, ear-coverts, throat and underparts white, thighs black and white, belly to undertail-coverts light chestnut; underwing-coverts white, spotted black near outer edge; iris dark brown; bill and legs black. Differs from *L. leucomela* mainly in lack of prominent white forehead and supercilium, and in having chestnut (not orange-buff) lower underparts; from *L. sueurii* and *L. tricolor* in having white on upperwing-coverts, chestnut belly to undertail-coverts. Female, juvenile and immature undescribed. Voice. Short nasal calls, e.g. "tchu", often repeated in short phrases, e.g. as "tchow-tchow-de-weet".
Habitat. Forest; possibly only in closed forest in hills.
Food and Feeding. No information. Diet probably similar to that of *L. leucomela*. Likely to forage in canopy.
Breeding. No information.
Movements. Presumably sedentary.
Status and Conservation. Not globally threatened. Status not properly assessed, as this taxon has usually been considered conspecific with more widespread *L. leucomela*. Population and precise area occupied on Mussau not recorded. Should perhaps be classified as Vulnerable, at best, in view of its very restricted range and the extensive logging that has occurred, and continues, on the island.
Bibliography. Coates (1990), Dutson (2005d), Mayr (1955), Rothschild & Hartert (1924).

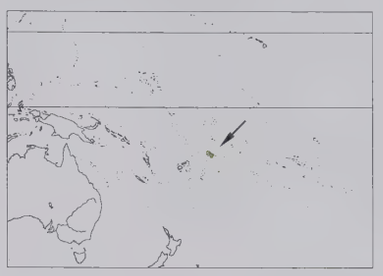
62. Polynesian Triller

Lalage maculosa

French: Échenilleur de Polynésie **German**: Südseelalage **Spanish**: Oruguero Polinesio
Other common names: Spotted Triller

Taxonomy. *Colluricincla maculosa* Peale, 1848, Upolu, Samoa.
Sixteen subspecies recognized.
Subspecies and Distribution.
L. m. melanopygia Mayr & Ripley, 1941 – Santa Cruz Is (Utupa, Ndeni).
L. m. vanikorensis Mayr & Ripley, 1941 – Santa Cruz Is (Vanikoro).
L. m. modesta Mayr & Ripley, 1941 – N & C Vanuatu (Espíritu Santo, Malo, Pauuma, Epi).
L. m. ultima Mayr & Ripley, 1941 – C Vanuatu (Efaté I).
L. m. rotumae Neumann, 1927 – Rotuma I (N of Fiji).
L. m. mixta Mayr & Ripley, 1941 – NW & C Fiji Is (Yasawa, Naviti, Yadua, Ovalau, Mathuata, Mathathoni Levu).
L. m. woodi Wetmore, 1925 – N Fiji (Vanua Levu, Kioa, Taveuni, Qamea).
L. m. pumila Neumann, 1927 – SW Fiji (Viti Levu).
L. m. soror Mayr & Ripley, 1941 – SW Fiji (Kadavu).
L. m. nesophila Mayr & Ripley, 1941 – Lau Archipelago (E of Fiji).
L. m. futunae Mayr & Ripley, 1941 – Wallis and Futuna Is.
L. m. maculosa (Peale, 1848) – Samoa (Savai'I, Upolu).
L. m. keppeli Mayr & Ripley, 1941 – Tafahi I and Niuatoputopu I (N of Tonga)
L. m. vauana Mayr & Ripley, 1941 – N Tonga Is (Vava'u Group).
L. m. tabuensis Mayr & Ripley, 1941 – Tonga (except Vava'u Group).
L. m. whitmeei Sharpe, 1878 – Niue I (E of Tonga).



Descriptive notes. 15–16 cm; c. 30 g. Male nominate race has broad white supercilium, black line through eye to nape; neck sides white, almost forming collar on hindneck; top of head and upperparts greenish-black, rump and uppertail-coverts grey, barred buffy white and blackish; lesser upperwing-coverts like back, median coverts white, outermost with black centres, greater coverts black, tipped white, inner ones also broadly edged white; alula and primary coverts black; remiges black, edged white, white broader on secondaries and tertials; rectrices black, tipped white, white broader on outer feathers; cheeks, ear-coverts, throat and underparts, including axillaries and underwing-coverts, white; iris dark brown; bill all bluish-black, or with lower mandible yellow with dark tip; legs grey to black. Differs from *L. leucopyga* in having prominent supercilium, shorter tail. Female is browner than male on upperparts and wings, but top of head greenish-black, contrasting with back; upperpart feathers edged light brown, rump and uppertail-coverts ashy, faintly edged pale buffy and barred black, white margins of remiges and wing-coverts narrow (not forming distinct patch), rectrices brown, tipped white; underparts white, head side, breast side and flanks barred dusky black. Immature is blackish above, crown streaked tawny or white, back feathers sometimes tipped tawny, rump buffy grey, wings dark brown with white areas tinged tawny, tail dark brown, tipped white, white of head and underparts tinged buff and irregularly barred black; juvenile as immature, upperparts with buffy-white feather tips. Races vary considerably in colour and pattern, e.g. Fiji races are browner above and barred below: *futunae* has white-barred blackish rump, more white on upperwing-coverts; *whitmeei* has darker rump, shorter supercilium (not reaching white of neck side); *keppeli* has nape almost white, forming white collar, white feather tips on upperparts, pale grey rump; *nesophila* is like previous, but with less white on back and collar; *vauana* has white streaks on crown, partial white nuchal collar; *tabuensis* is similar to last, but collar more pronounced and feathers of back tipped white; *vanikorensis* is also similar, but smaller, with no collar; *melanopygia* resembles previous, but has blacker upperparts, including rump; *modesta* is larger than last two, with greyer rump, more barring on underparts, buffy wash on breast; *ultima* is larger, with pronounced barring on back, more grey on rump, pure white underparts; *pumila* has head side and underparts washed buffy brown and heavily barred; *soror* is similar but less heavily barred; *rotumae* has underparts washed bright tawny, less strongly barred; *mixta* is more rusty-tinged on upperparts and washed buff on underparts, bars restricted to breast side; *woodi* is more like nominate, but has white-streaked crown, white feather tips on upperparts, heavily barred underparts. Voice. Call is a loud "tchick"; also gives a loud, ringing "peach-it" or "pee-chew" after short flights.
Habitat. Forest and forest edges, from lowlands to mountains; often found also in gardens and parks, and at roadsides.
Food and Feeding. Food insects "and other animals". Often forages on ground. No other information available.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Vanuatu and Temotu EBA, Fiji EBA and Samoan Islands EBA. Current status not well known. Recently thought to be common throughout Vanuatu and Santa Cruz Is. Formerly considered widespread and common on most islands in Fiji (including Rotuma) and Tonga, and on Futuna, Wallis, and the two Samoan islands (Savai'i, Upolu).
Bibliography. Beichle & Baumann (2003), Birchenough *et al.* (2003), Bregulla (1992), Doughty *et al.* (1999), Guyot & Thibault (1988), Holyoak (1979), Mayr (1978), Mayr & Ripley (1941), Michaux (1998), Muse & Muse (1982), Pratt *et al.* (1987), Reed (1980), Rinke (1987), Steadman & Franklin (2000), Steadman & Freifeld (1998), Steadman *et al.* (1999), Watling (1982, 2001).

63. Samoan Triller

Lalage sharpei

French: Échenilleur des Samoa **German**: Braunrückenlalage **Spanish**: Oruguero de Samoa

Taxonomy. *Lalage sharpei* Rothschild, 1900, Upolu, Samoa.
Sometimes placed in a monotypic genus, *Oscarornis*, on grounds of its juvenile-type plumage and lack of sexual dimorphism. Two subspecies recognized.
Subspecies and Distribution.
L. s. tenebrosa Mayr & Ripley, 1941 – Samoa (Savai'i).
L. s. sharpei Rothschild, 1900 – Samoa (Upolu).

Descriptive notes. 13 cm. Distinctive triller. Nominate race has forehead and top of head down to base of eye, and nape, mantle, back and scapulars hair-brown with darker feather shafts; rump and uppertail-coverts darker, more olive-brown; wings blackish-brown, all coverts and remiges narrowly fringed whitish, more buffy to tawny on outer edges of greater coverts and remiges; rectrices hair-brown with pale feather tips; ear-coverts and neck side rufous-buff, barred brown; underparts white, washed buff, and irregularly barred dark brown on side of neck, across breast and on flanks; iris white; bill bright red-orange; legs dark brown. Sexes alike. Juvenile and immature undescribed. Race *tenebrosa* is much darker brown than nominate on upperparts and upperwing, sometimes almost blackish on ear-coverts and neck side, barring on underparts much heavier. Voice. Thin, squeaky, ascending or descending trill, sounding as if forced out with great effort.
Habitat. Primary and secondary forest and forest edge; also occurs rarely in cattle pasture with undergrowth and trees, and in traditional plantations with few permanent houses. From 200 m to above 600 m.
Food and Feeding. Eats fruit and invertebrates. Moves rather slowly, gleaning from leaves of shrubs and small trees. No other information.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Samoan Islands EBA. Generally uncommon. In a 1984 survey, on Upolu, found to be not common in the O le Pupu-pu'e National Park, which is unmanaged and which had been severely damaged by cyclones; the park threatened by logging and cattle farming. This species is almost certainly sedentary, and requires the full and effective protection of primary forest if its future survival is to be secured.
Bibliography. Armstrong (1932), Beichle & Baumann (2003), Beichle & Maelzer (1985), Bellingham & Davis (1998), Collar *et al.* (1994), Elmqvist *et al.* (1994), Mayr & Ripley (1941), Michaux (1998), Muse & Muse (1982), Pratt *et al.* (1987), Reed (1980), Stattersfield & Capper (2000), Watling (1982, 2001).

64. Long-tailed Triller

Lalage leucopyga

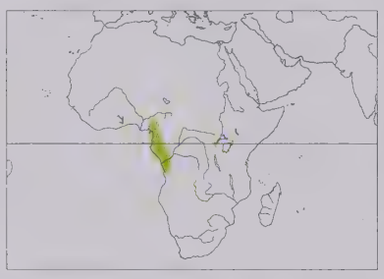
French: Échenilleur pie **German**: Langschwanzlalage **Spanish**: Oruguero Colilargo

Taxonomy. *Symmorphus leucopygus* Gould, 1838, "New South Wales"; error = Norfolk Island.
Nominate race extinct. Five extant subspecies recognized.
Subspecies and Distribution.
L. l. affinis (Tristram, 1879) – SE Solomons (San Cristobal, Uki).
L. l. deficiens Mayr & Ripley, 1941 – Torres Is and Banks Is.
L. l. albiloris Mayr & Ripley, 1941 – N & C Vanuatu.
L. l. simillima (F. Sarasin, 1913) – S Vanuatu and Loyalty Is.
L. l. montrosieri J. Verrreaux & Des Murs, 1860 – New Caledonia.

Descriptive notes. 17–18 cm; 16·5–21 g. Male nominate race breeding with forehead, lores, crown, upper ear-coverts and upperparts glossy greenish-black, indistinct white spots on lores; rump white, strongly tinged buff, uppertail-coverts dark grey; wings black, secondaries, tertials and inner primaries narrowly edged white, lesser, median and inner greater upperwing-coverts white; rectrices black, broadly tipped white (except on central pair), white increasing in extent on outer feathers, with outermost white on terminal half; cheeks, lower ear-coverts, throat and entire underparts, including underwing-coverts, white, strongly washed buff, especially on breast and flanks; iris, bill and legs black. Differs from *L. maculosa* in having longer tail, no supercilium, brighter glossy black upperparts. Non-breeding male is browner, with blackish feather centres on head, whitish lores, sandy fringes on uppertail-coverts. Female is similar to non-breeding male, but has upperwing-coverts washed sandy-buff and edged brown, secondaries edged sandy, underparts with vestigial barring on side of breast. Juvenile has buffy barring on crown, mantle and back, brown remiges and rectrices tipped white, some faint brown streaks on throat and breast; immature similar to adult female, but more heavily washed buff on underparts, has white lores, and white on wing washed tawny. Race *montrosieri* is smaller, with rump grey-white, less white on upperwing-coverts, female less deeply buff on rump and underparts; *simillima* is similar to previous but rather smaller, with less white on wing and tail, and with buff on underparts confined to breast, female much darker than previous; *albiloris* is smaller than last, with rump greyer, lores white (often extended to form a supercilium), less white in wing (only median coverts white), often female also has marked supercilium; *deficiens* is like previous, but has less white in tail, and lacks supercilium; *affinis* has rump pure white, white in tail restricted to outer four rectrices, white in wing restricted to median coverts. Voice. Gives a short, rasping call note; loud, melodious song, "tee-zeeia-tee-zeeia-tee-zeeia". Nominate race was reported to give a single harsh chirp.
Habitat. Lowland and mountain forest; commoner at forest edges and in open areas. Probably occurred in all wooded habitats on Norfolk I.

On following pages: 65. Petit's Cuckoo-shrike (*Campephaga petiti*); 66. Black Cuckoo-shrike (*Campephaga flava*); 67. Red-shouldered Cuckoo-shrike (*Campephaga phoenicea*); 68. Purple-throated Cuckoo-shrike (*Campephaga quiscalina*); 69. Western Wattled Cuckoo-shrike (*Lobotos lobatus*); 70. Eastern Wattled Cuckoo-shrike (*Lobotos oriolinus*).

Food and Feeding. No current information available. On Norfolk I (nominate race, extinct) foraged in trees, but also seen to forage in wet grass, perching on stumps and fences before pouncing on insects on the ground; observed also to take insects on the wing.
Breeding. No current information. On Norfolk I bred in Sept, Dec and Feb, Feb clutches apparently second breeding attempt in response to food abundance after heavy rainfall; nest a shallow cup of moss, lichen and fibrous roots, lined with finer material, placed in tree, including introduced pine (*Pinus*); clutch usually 2 eggs, occasionally 3.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in the Solomon Group EBA, Vanuatu and Temotu EBA and New Caledonia EBA; extinct in Norfolk Island EBA. Common throughout New Caledonia and Vanuatu. Common on the Solomon islands of San Cristobal and Uki, where occurs in Hauta Conservation Area. Nominate race last recorded on Norfolk I in 1942, despite its apparent abundance in 1941; predation by newly arrived black rats (*Rattus rattus*) probably the main cause of extinction, but disappearance also coincided with habitat loss after forest clearance for an airport.
Bibliography. Birchenough *et al.* (2003), Bregulla (1992), Christidis & Boles (1994), Doughty *et al.* (1999), Hermes (1985), Mayr (1955, 1978), Mayr & Ripley (1941), Michaux (1998), Schodde & Mason (1999), Vuilleumier & Gochfeld (1976).



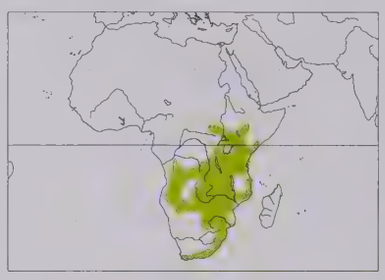
Genus *CAMPEPHAGA* Vieillot, 1816

65. **Petit's Cuckoo-shrike**

Campephaga petiti

French: Échenilleur de Petit **German**: Kongoraupenfresser **Spanish**: Oruguero de Petit

Taxonomy. *Campephaga petiti* Oustalet, 1884, Cacongo (Landana), Cabinda, Angola.
Forms a superspecies with *C. flava* and *C. phoenicea*. Possible hybridization with first of those in NW Angola and E DRCongo (L Kivu) suggested by observations of females or young males having barred underparts with strong yellow wash. Monotypic.
Distribution. SE Nigeria and SW Cameroon S to NW Angola; also NE DRCongo, adjacent SW Uganda and W Kenya.



Descriptive notes. 20 cm; 26–37 g. Male is black with greenish-blue gloss (forehead, belly, thighs and underwing-coverts unglossed); rectrices and remiges edged greenish-blue; iris deep brownish-black; bill black, large yellow or orange gape wattles; legs black. Distinguished from *C. flava* by larger gape wattles, black (not olive-black) underwing-coverts, never any yellow on upperwing-coverts; from *C. phoenicea* by lack of coloured "shoulder" patch; from very similar *C. quiscalina* by lack of purple gloss on breast and head side, larger gape wattles. Female is very different, has buff supercilium, blackish-brown lores and streak behind eye, white broken eyering, olive ear-coverts streaked pale yellow or white; top of head to upper mantle olive-green, lower mantle to uppertail-coverts olive-yellow, barred black, upperwing-coverts black, fringed yellow, flight-feathers black, edged yellow; central four rectrices olive-green, tipped yellow, other rectrices blackish, edged olive, and with yellow at tip becoming more extensive until outermost almost entirely yellow; chin and upper throat white or pale yellow, underparts rich yellow with variable amount of dark barring on side of breast and neck, yellow underwing-coverts and axillaries. Juvenile is similar to female, but top and side of head dark green with indistinct blackish bars, mantle and upper back olive-green, barred blackish, rest of upperparts yellow, barred black, underparts yellow, spade-shaped spots on side of neck, breast, flanks and undertail-coverts; immature not fully described. Voice. Short whistled "seep". Song a high-pitched "psiuu, tsi-tsi"; also high, scratchy warbling "sueet-sueet, siueet-seet-seet-sireet".
Habitat. Moist primary and secondary forest, including secondary growth, gallery forest and forest patches in savanna; in Uganda (Kibale Forest), commonest in logged areas with dense undergrowth and sparse canopy. Ecologically segregated by forest habitat from *C. phoenicea* in areas of range overlap. Mainly at 1000–2000 m, but also near sea-level.
Food and Feeding. Eats caterpillars (Lepidoptera), also flying insects and grasshoppers (Orthoptera). Forages unobtrusively in foliage of higher and middle canopy, also sometimes in undergrowth.
Breeding. Breeds in Feb–May in DRCongo and Jun in Uganda; courtship noted in Jun–Jul in Kenya; birds in breeding condition in Jul in Gabon and Sept in Angola. One nest (Uganda) was a cup of lichens and mosses, placed c. 13 m up on branch fork near top of a forest tree. No other information.
Movements. Recorded as absent from Kivu, in E DRCongo, in Jul–Nov, possibly indicating some movements.
Status and Conservation. Not globally threatened. Poorly known. Regarded as generally uncommon to locally frequent; locally common in W Kenya (Kakamega). This species' numbers have presumably been reduced by forest destruction, but in Uganda it is known to survive well in logged forest.

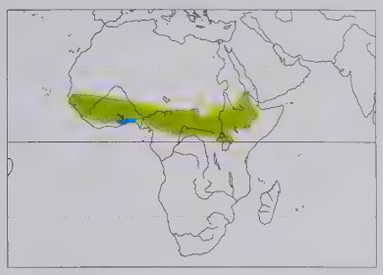
Ash *et al.* (1989), Bannerman (1953), Bennun & Ngoroje (1999), Borrow & Demey (2001), Buckley & McNeilage (1989), Byaruhanga *et al.* (2001), Chapin (1953), Dean (2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1991), Elgood *et al.* (1994), Fishpool & Evans (2001), Hall & Moreau (1970), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette & Prévost (1987), Mackworth-Praed & Grant (1960, 1963, 1973), Mann (1985), Prigogine (1980a), Sekercioglu (2002), Skorupa (1982), Vande weghe (1988), Zimmerman *et al.* (1996).

66. **Black Cuckoo-shrike**

Campephaga flava

French: Échenilleur à épaulettes jaunes **Spanish**: Oruguero Hombroamarillo
German: Mohrenraupenfresser
Other common names: African Black Cuckoo-shrike

Taxonomy. *Campephaga flava* Vieillot, 1817, South Africa.
Forms a superspecies with *C. petiti* and *C. phoenicea*. Possible hybridization with *C. petiti* in NW Angola and E DRCongo (L Kivu) is suggested on the basis of observations of females or young males having barred underparts with a strong yellow wash. Where breeding range overlaps with that of *C. phoenicea* (in SW Ethiopia and W Kenya), no intermediate males have been reported; some females of present species from C & E Kenya (outside range of *C. phoenicea*) have yellow in tail intermediate in extent between typical females of the two species; in areas where males and females of both species occur, all three female tail patterns are found, but differences are not clearly enough defined to point to further intergradation, although interbreeding may indeed occur. Monotypic.
Distribution. S Sudan and SW Ethiopia S to Uganda, Kenya and S Somalia, thence S to S DRCongo, Angola, N Namibia, N & E Botswana and N South Africa and Swaziland, S along coast to Western Cape.



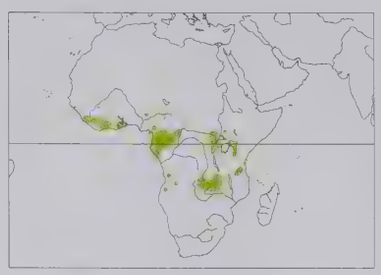
Descriptive notes. 19–22 cm; 27–40 g. Male is black, glossed greenish-blue; often has yellow lesser upperwing-coverts forming patch at bend of wing; iris blackish; bill black, gape yellow; legs black. Distinguished from very similar *C. petiti* by smaller yellow gape, from *C. quiscalina* by lack of purple gloss on face, neck and underparts, and by yellow (not orange) gape, from both also by yellow on wing (when present); "yellow-shouldered" male differs from very similar *C. phoenicea* in having normally smaller, less orangey patch confined to lesser coverts, although a few individuals may not be distinguishable. Female is very different, olive-green to olive-brown above, but rump and uppertail-coverts grey or brown with black bars that extend variably to back and scapulars; whitish supercilium, black streak through eye; flight-feathers and wing-coverts edged or fringed yellow, tail blackish-brown, outer feather pair yellow except for base of inner web; white with blackish bars and crescentic marks below, yellow wash on breast side often extending across breast and on to flanks, bright yellow underwing-coverts. Juvenile is similar to female, but entire head and upperparts barred blackish, underparts more heavily and broadly barred, bars becoming spade-shaped on belly; immature very similar to adult. Voice. Often silent, but sometimes a high-pitched, penetrating, insect-like trill, "krrreee", lasting c. 1 second, when foraging or in flight. Other calls include lower-pitched, downslurred "chweeu" or "kreeu", short "chip", "chup" or "tsip", hissing "sseeu", also a repeated unmusical "chwrr" as alarm, also a soft, repeated "seeu", a quiet peeping when foraging, and various squeaks.
Habitat. Can occur in virtually any woodland or forest habitat, from acacia (*Acacia*), mopane (*Colophospermum mopane*) and brachystegia (*Brachystegia*) woodland to riparian forest, the edges of evergreen forest and secondary growth; less commonly in savanna, scrub, semi-arid bush, gardens and exotic plantations. In E Africa occurs in forest from sea-level to 1800 m, breeding above 900 m; in SC Africa breeds mainly in woodland at 1000–2000 m, but occurs in riverine and forest habitats down to 50 m outside breeding season; breeds near sea-level in Cape region. In areas of geographical overlap with *C. petiti*, largely ecologically separated by its preference for woodland and forest edge, rather than true forest. In areas of overlap with *C. phoenicea* both species recorded in variety of habitats, including juniper (*Juniperus*) forest in S Ethiopia, but present species usually in less thick vegetation.
Food and Feeding. Food primarily insects, mainly lepidopterans (especially caterpillars, including hairy ones), also termite alates (Isoptera), and orthopterans, including katydids (Tettigoniidae); also eats spiders (Araneae) and ants (Hymenoptera); fruit and tree seeds also taken. Normally forages within and at edge of canopy, occasionally on the ground. Usually moves quickly from tree to tree; often joins mixed-species parties. Forages by searching leaves, bark and lichens; prey caught in fluttering hops, sometimes (e.g. termite alates) in short flights; sometimes hovers to pick prey from leaves.
Breeding. Breeds mainly during rains: in Apr in Ethiopia, Mar–May in Kenya, Dec–Feb and Apr–May in Tanzania, Oct in Zanzibar; Oct–Jan in SE DRCongo, Zambia and Malawi, Sept–Feb in Zimbabwe, Sept–Jan in Mozambique, Nov in Botswana; Oct–Jan, rarely Sept and Feb, in South Africa. Monogamous; territorial. In apparent courtship display, a pair called with trills and the male performed fluttering, moth-like flight with the tail depressed, after which the female joined the male, flicking her wings. Nest built by female, accompanied by male, a small shallow cup of moss, leaf petioles, lichen and bearded lichens (*Usnea*), lined with fine fibres, hair and leaf midribs, and bound with spider webs; moulded into flat fork or saddle, usually 5–18 m up in tree, often far out on branch, and easily overlooked. Eggs 1–3, usually 2; incubation by female only, period 20 days; male feeds female and defends area near nest; chicks fed by both parents, fledge at 20–23 days.
Movements. Resident, nomadic or migratory. Local appearances often irregular. In S Africa, breeds in plateau country from Sept/Oct and then moves to lower altitudes from Apr/May onwards; movements apparently influenced by rainfall, fewer birds moving away from breeding areas in wet years. Many move N to equator after breeding; mainly a non-breeding visitor to Kenya, N Tanzania, Uganda and Rwanda in Apr–Sept, Somalia Jun–Oct and S Sudan during rains. In S Africa, post-breeding movements appear to be E, probably into Mozambique and major valley systems (such as that of R Zambezi). Some "overwintering" recorded in Zambia (E of 25° E) and NE South Africa; occurs in S coastal regions throughout year. Attracted to lights at night in SE Kenya (Ngulia) during Nov–Jan.
Status and Conservation. Not globally threatened. Widespread; probably common but status difficult to ascertain, as probably under-recorded owing to its unobtrusiveness. Generally regarded as uncommon to frequent, and seasonally common in Kenya, Zambia, S Mozambique and N South Africa; in last-mentioned, density 1 pair/30 ha. No information on any change in overall distribution, but numbers have probably declined as a result of widespread destruction of woodland and forest throughout its range. Species is apparently relatively undisturbed by presence of humans, as it forages and nests in gardens. Occurs in a large number of protected areas over its extensive range.
Bibliography. Anon. (2001a), Ash & Miskell (1983), Backhurst & Pearson (1977), Benson & Benson (1977), Brewster (1998), Britton (1973), Brooke (1970), Byaruhanga *et al.* (2001), Campbell (1998), Chapin (1953), Clancey (1964, 1971, 1976), Crouch (1997), Dean (2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Ginn *et al.* (1989), Hall & Moreau (1970), Hanmer (1985), Harrison *et al.* (1997), Herremans (1998), Irwin (1981), Keith *et al.* (1992), Lewis & Pomeroy (1989), Macdonald (1984a), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993), Mlingwa (2000), Monadjem (1996, 2001a, 2002a, 2002b), Nikolaus (1987), Oatley (1969), Pakenham (1979), Patten (1999), Penry (1994), Prigogine (1972), Sinclair & Hockey (1996), Skead (1966), Skinner (1995), van Someren (1956), Steyn (1996), Symes *et al.* (2002), Tarboton (1980, 2001), Tarboton *et al.* (1987), Vande weghe (1988), Vincent (1949), Zimmerman *et al.* (1996).

67. **Red-shouldered Cuckoo-shrike**

Campephaga phoenicea

French: Échenilleur à épaulettes rouges **Spanish**: Oruguero Hombrorrojo
German: Rotschulter-Raupenfresser

Taxonomy. *Ampelis phoenicea* Latham, 1790, Gambia.
Forms a superspecies with *C. petiti* and *C. flava*. Where breeding range overlaps with that of latter (in SW Ethiopia and W Kenya), no intermediate males known; extralimitally (in C & E Kenya), some females have extent of yellow in tail intermediate between that shown by present species and that of typical *C. flava*, suggesting possible incomplete genetic isolation. Monotypic.
Distribution. Extreme S Mauritania, Senegal and Gambia E to S Chad, S Sudan, Ethiopia and Eritrea, S to Sierra Leone, N Ivory Coast, SE Ghana, SE Cameroon, N PRCongo, N DRCongo, Uganda and extreme W Kenya.



Descriptive notes. 20 cm; 23–35·5 g. Male is black, glossed greenish-blue, with red, orange or orange-yellow lesser and median upperwing-coverts ("shoulder" patch); iris black, dark brown or grey; bill black, gape yellow; legs black. Distinguished from most congeners by orange or red wing-covert patch; from very similar *C. flava* possessing yellow lesser coverts by fact that patch on present species is larger, but a few individuals may not be distinguishable. Female is brown to grey-brown above, black barring on rump and uppertail-coverts (sometimes extending to back and scapulars), pale grey supercilium contrasting with dark lores and line through eye; flight-feathers and wing-coverts edged or fringed yellow, tail brownish-black, outer rectrices tipped and edged yellow; white with black bars and crescentic marks below, breast side and flanks variably washed yellow, bright yellow underwing-coverts. Juvenile is similar to female, but upperparts barred black, outer tail feathers striped dark and yellow, underparts more heavily barred than adult, bars tending towards spade-shaped blotches on belly; immature not fully described. Voice. Mainly silent. Song, often as duet, a jumble of high-pitched whistles, squeaks and churrs, reminiscent of a "good-quality" song of sunbird (Nectariniidae), continuing for 5–10 seconds. Calls include clear, loud whistle, "heew" or "huu-tseew", burbled "t-chew" or "ti-chulu" notes in flight, often repeated, and short "tsuck"; contact call a sharp, repeated "tchit" or "tchit-tchiwi-tchiwi".
Habitat. Forest patches, including edges and clearings, gallery forest, moist secondary growth, wooded grassland and thickets in savanna. Usually in thicker vegetation than that occupied by *C. flava* in E Africa, but both species recorded in variety of habitats, including juniper (*Juniperus*) forest in S Ethiopia. From sea-level to c. 1600 m. In areas of geographical overlap with *C. petiti*, ecologically separated by its preference for woodland and forest edge, rather than true forest.
Food and Feeding. Eats caterpillars (Lepidoptera) and other insects, especially orthopterans and bugs (Hemiptera). Keeps to upper or middle storeys; occasionally lower (W Africa) or in bushes and small trees (E Africa), between which it flies in low undulating flight. Forages quietly, mainly within foliage, by gleaning from leaves, twigs and branches; sometimes takes prey on the ground and in flycatching sallies. Occasionally joins mixed-species flocks.
Breeding. Breeds during rains, May–Sept in Nigeria, Jul in W Sudan (Jun in S) and Mar–Apr in Uganda; carrying nesting material in Aug in Gambia; nest-building in Jun in Kenya. Monogamous. Nest a small, shallow cup of moss and lichens, bound with spider webs, c. 10 m up and well concealed in fork of leafless tree. Two clutches each contained 2 eggs. No other information.
Movements. Migratory in W Africa (E of c. 8° E) and in Sudan, moving N to breed during rains and returning to edge of forest belt at lower latitudes in dry season; in Nigeria occurs in S guinean zone all year, but moves N to Zaria in May–Nov and S to coast Nov–Apr; resident in Uganda, with population increase Jan–Apr probably involving non-breeding migrants from N tropics. Elsewhere, apparently sedentary or nomadic. Vagrant in W DRCongo (near Lukolela) and NE Rwanda.
Status and Conservation. Not globally threatened. Widespread, and uncommon to locally common. No information on effects of habitat loss, but this species' numbers may have been reduced by forest destruction.
Bibliography. Bannerman (1953), Barlow *et al.* (1997), Benson *et al.* (1971), de Bie & Morgan (1989), Bobo *et al.* (2005), Borrow & Demey (2001), Britton (1973), Byaruhanga *et al.* (2001), Chapin (1953), Crisler *et al.* (2003), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fry (1980), Giraudoux *et al.* (1988), Gore (1990), Grimes (1987), Hall & Moreau (1970), Hutchins *et al.* (2002), Jackson & Sclater (1938), Keith *et al.* (1992), Lewis & Pomeroy (1989), Macdonald (1984b), Mackworth-Praed & Grant (1960, 1973), Nikolaus (1987), Pearson (1990), Thiollay (1998), Turner (1991), Vernon (1980), Williams (1992), Zimmerman *et al.* (1996).

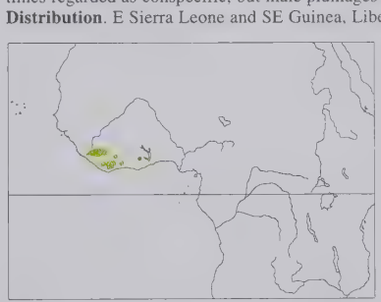
68. **Purple-throated Cuckoo-shrike**

Campephaga quiscalina

French: Échenilleur pourpré **German**: Purpurraupenfresser **Spanish**: Oruguero Purpúreo

Taxonomy. *Campephaga quiscalina* Finsch, 1869, Fanti, Ghana.
Three subspecies recognized.
Subspecies and Distribution.
C. q. quiscalina Finsch, 1869 – Sierra Leone, S Guinea, N Liberia, S Mali, Ivory Coast, C Ghana, W Togo, C Nigeria, W & SW Cameroon and SW Central African Republic S to PRCongo and Angola.
C. q. martini (Jackson, 1912) – S Sudan, NE & SE DRCongo, C Uganda, W Kenya and Zambia.
C. q. munzneri Reichenow, 1915 – E Tanzania.
Descriptive notes. 20 cm; male mean 39·7 g, female 30–43 g. Male nominate race is black, glossed steel-blue, but with purple gloss on ear-coverts, cheeks, underwing-coverts and axillaries, and from chin to breast, and blue-purple on hindneck and belly; secondaries, tertials and upperwing-coverts edged glossy blue, rectrices edged steel-blue; iris dark brown or red-brown; bill black, gape yellow to orange; legs dark brown to blackish. Distinguished from very similar *C. petiti*, and from *C. flava* and *C. phoenicea*, by strong purple gloss on face, throat and breast. Female has grey-white supercilium, black streak from lores through eye, white broken eyering, white streaks on cheeks and ear-coverts; top of head to upper mantle grey, rest of upperparts, including scapulars, yellowish-green; wings brown, feathers edged green; rectrices brown, washed green, outer four with yellow tips, yellow becoming broader outwards, outermost rectrix entirely yellow on outer web and fringe of inner web; chin and throat white, underparts bright yellow to orange-yellow,

underwing-coverts and axillaries yellow; no noticeable bright colour at gape. Juvenile is like female, but top of head browner, head, upperparts, upperwing-coverts and tertials variably barred black and white, chin and throat pale grey, underparts yellow with dark barring, bars becoming narrower with age; immature not fully described. Race *martini* has dusky grey barring on upper breast of female; *munzneri* is like previous, but throat of male glossed steel-blue. Voice. Song a rather fast series of melodious whistles, "slueet-slueet-swit-wit-slueet-slueet-swit-wit-tluw-tluweew"; contact call "whit-whit-whit" or "tsee-up"; young near nest give high-pitched, penetrating "tseeoo".
Habitat. Moist primary and secondary evergreen forest, especially edges and clearings; also found in gallery forest, riparian forest, dry evergreen forest, coffee forest, forest patches in savanna, and regenerating forest including adjacent scattered trees, shrubs and bushes. Mainly lowlands, but to 1500 m in Zambia; in Kenya occurs only at 1500–2500 m.
Food and Feeding. Food insects, mainly lepidopterans (especially caterpillars, also adult moths), orthopterans, bugs (Hemiptera, including cicadids) and hymenopterans; also takes spiders (Araneae). Forages unobtrusively in canopy; sometimes joins mixed-species flocks. Searches creepers and foliage, and catches prey under leaves and on trunks.
Breeding. Breeds during and at end of rains, in Aug, Nov and Dec in Gabon, Mar and Sept in Angola, May, Jul and Aug in DRCongo, Apr–May in Sudan, Jun, Oct and Dec in Kenya and Nov and Jan in Zambia. Monogamous; probably territorial. Nest built by female, accompanied by male, a small, shallow cup of lichens, bound with spider webs and lined with fine fibres and moss, secured to horizontal tree branch 6–30 m above ground. Eggs 2; incubation by female only, male guards nest in her absence, period 20 days; chicks fed and brooded initially by female, later fed by both parents, leave nest at 22 days.
Movements. None recorded; sedentary at least in Gabon and Zambia.
Status and Conservation. Not globally threatened. Uncommon to frequent throughout most of its range; locally common in Kenya, Zambia and Angola. As with its congeners, this species' numbers have probably declined as a result of the destruction of its forest habitats; present distribution fragmented, with populations present in surviving evergreen forest in equatorial and SC Africa. Occurs in a number of protected areas, including e.g. Taï Forest National Park and Lamto Research Station, in Ivory Coast.
Bibliography. Bannerman (1953), Bennun & Ngoroje (1999), Benson *et al.* (1971), Brosset (1972), Brosset & Érard (1986), Burgess & Mlingwa (2000), Byaruhanga *et al.* (2001), Chapin (1953), Cheke & Walsh (1996), Dean (2000), Demey (1999), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fishpool (1993), Gatter (1997), Grimes (1987), Hall & Moreau (1970), Hamel (1980), Jackson, C. (1997), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1963, 1973), Madge (1972), Muriuki *et al.* (1997), Nikolaus (1987), Pearson (1990), Prigogine (1980a), Scott (1996), Wilson & Wilson (1994), Zimmerman *et al.* (1996).



Genus *LOBOTOS* Reichenbach, 1850

69. **Western Wattled Cuckoo-shrike**

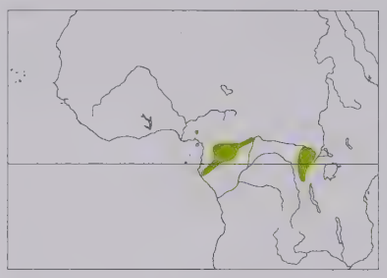
Lobotos lobatus

French: Échenilleur à barbillons **Spanish**: Oruguero Carunculado
German: Westlicher Lappenraupenfresser
Other common names: Ghana Cuckoo-shrike; Wattled Cuckoo-shrike (when treated as conspecific with *L. oriolinus*)

Taxonomy. *Ceblepyris lobatus* Temminck, 1824, Sierra Leone; error = Ghana.
Genus often merged with *Campephaga*, but separation appears justified on basis of colourful plumage, facial wattles, and sexual plumage similarity. Forms a superspecies with *L. oriolinus*; sometimes regarded as conspecific, but male plumages distinct. Monotypic.
Distribution. E Sierra Leone and SE Guinea, Liberia, Ivory Coast and SW Ghana.

Descriptive notes. 19–21 cm; 29–37 g. Male has glossy blue-black head, nape and throat, large orange gape wattles, narrow yellow collar; olive-yellow upperparts becoming orange-chestnut on rump; alula and flight-feathers black, yellow edges of secondaries and tertials; black tail with green centre and yellow corners; orange-chestnut breast, shading to yellow on undertail-coverts; yellow underwing; iris dark brown to red-brown; bill and legs black. Differs from *L. oriolinus* in having orange-chestnut rump, deeper orange-yellow underparts. Female is duller, with no gloss on head, no yellow collar, olive-green upperparts, underparts entirely yellow, gape wattles smaller; virtually indistinguishable from female *L. oriolinus*. Juvenile is similar to female, but upperparts and underparts with slight dark barring, flight-feathers and greater upperwing-coverts tipped white, tail feathers narrower and more pointed than adult; immature not fully described. Voice. Mainly silent and inconspicuous, with "zit" or "tsik" flight call.
Habitat. Upper guinean forest zone, in canopy of primary forest or tall lowland rainforest, often near rivers, and in open swamp-forest. Also recorded in logged, disturbed and managed forest; also in *Terminalia ivorensis* plantations in Ivory Coast.
Food and Feeding. Diet includes caterpillars (Lepidoptera), grasshoppers (Orthoptera), mantids (Mantodea) and seeds. Generally perches in dense, high foliage, typically 20–50 m above the ground. Often joins mixed-species parties.
Breeding. Birds in breeding condition in Feb and Aug–Nov in Liberia. No other information.
Movements. None recorded.

Status and Conservation. VULNERABLE. Restricted-range species: present in Upper Guinea Forests EBA. Local, and generally rare to uncommon. Although this species has apparently adapted to secondary and disturbed forest habitats, and is known to breed in mature logged forest, it must be seriously threatened by massive forest destruction throughout its restricted and fragmented range of 300,000 km². Population may be declining rapidly: surveys at Gola Forest, in Sierra Leone, in 1988–1989 indicate a serious decline and occurrence at very low densities. In Liberia, where forests under intense and increasing pressure from commercial logging, settlement and smallholder agriculture, it is locally rare to uncommon, with estimated minimum of 20,000 pairs in 1997. In Ivory Coast, sightings in Taï Forest National Park, one of the largest and best-preserved areas of upper guinean forest, suggest that it is secure there. Very few 20th-century records from Ghana. Unconfirmed 1988 report from SE Nigeria (Ikpan) probably refers to *L. oriolinus*.



Bibliography. Allport (1991), Allport *et al.* (1989), Ash *et al.* (1989), Bannerman (1953), Borrow & Demey (2001), Brosset & Érard (1986), Chapin (1953), Collar & Andrew (1988), Collar & Stuart (1985, 1988), Collar *et al.* (1994), Colston & Curry-Lindahl (1986), Demey & Fishpool (1991), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fishpool & Evans (2001), Gartshore (1989, 1991), Gartshore & Carson (1989), Gartshore *et al.* (1995), Gatter (1997), Grimes (1987), Hall & Moreau (1970), Halleux (1994), Keith *et al.* (1992), Prigogine (1953), Stattersfield & Capper (2000), Wood (1993).

70. Eastern Wattled Cuckoo-shrike

Lobotos oriolinus

French: Échenilleur loriot **German**: Östlicher Lappenraupenfresser **Spanish**: Oruguero Oriolino
Other common names: Oriole Cuckoo-shrike; Wattled Cuckoo-shrike (when treated as conspecific with *L. lobatus*)

Taxonomy. *Lobotus* [*sic*] *oriolinus* Bates, 1909, Assobam, River Bumba, Cameroon.
Genus often merged with *Campephaga*, but separation appears justified on basis of colourful plumage, facial wattles, and sexual plumage similarity. Forms a superspecies with *L. lobatus*; sometimes regarded as conspecific, but male plumages distinct. Monotypic.
Distribution. S Cameroon, SW Central African Republic, N PRCongo and Gabon, also E DRCongo; unconfirmed report from SE Nigeria (Ikpan).
Descriptive notes. 19 cm. Male has glossy blue-black head, nape, throat and upper breast, large orange gape wattles; bright yellow on upper mantle, becoming yellowish-green on lower mantle, back, scapulars and upperwing-coverts, yellower green on rump and uppertail-coverts; alula and flight-feathers black, white edges of primaries, yellow edges of secondaries, yellowish-green outer

webs of tertials; black tail with green centre and yellow corners; lower breast to undertail-coverts bright saffron-tinged yellow; iris dark brown; bill and legs black. Differs from *L. lobatus* in having yellow-green rump and uppertail-coverts, paler and yellower (less orange) underparts. Female is duller, with green wash on head, no saffron wash on underparts, smaller gape wattles; virtually indistinguishable from female *L. lobatus*. Juvenile male is similar to adult female, but has dull yellow frontal band, dull green forehead to forecrown, bluish-green supercilium and ear-coverts, blackish lores, indistinct pale eyering, buff chin, greenish-grey throat, bluish-green neck side and lower throat, faint dark barring on upperparts (including scapulars and upperwing-coverts) and underparts, white tips of greater and primary coverts, more pointed tail feathers; juvenile female undescribed; immature not fully described.
Voice. Mainly silent and inconspicuous, with "zit" or "tsik" flight call.
Habitat. Primary, secondary and transition forest at low altitudes; recorded also from edge of logged forest in Gabon. Most W African records are from near rivers, from sea-level to 700 m; occurs at 850–1300 m in E DRCongo.
Food and Feeding. Eats small caterpillars (Lepidoptera), grasshoppers (Orthoptera) and other insects. Frequents canopy of mature trees; often follows mixed-species parties of insectivores. Forages in manner of a flycatcher (Muscicapidae), sallying from a perch to take insects from under leaves.
Breeding. Laying dates Dec–Jan, Apr–Jun and Aug in DRCongo. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Data-deficient. There are very few documented sightings of this unobtrusive species, which is regarded as uncommon to very rare throughout its potentially wide range. An unconfirmed 1988 report of *Lobotos* from SE Nigeria (Ikpan) probably refers to this species. Reasons for its rarity unclear; it is thought not to be immediately threatened by habitat loss, as it appears to prefer secondary forest.

Bibliography. Bannerman (1953), Brosset & Érard (1986), Chapin (1953), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1998a), Elgood *et al.* (1994), Fishpool & Evans (2001), Hall & Moreau (1970), Keith *et al.* (1992), Languy *et al.* (2005), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1973), Pedersen (2000), Sinclair & Ryan (2003).

PLATE 11 ➤

PLATE 11

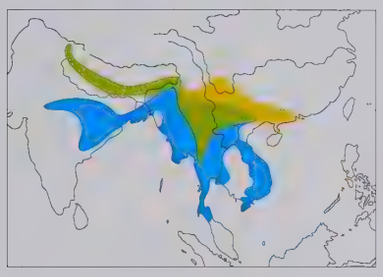
cm 8



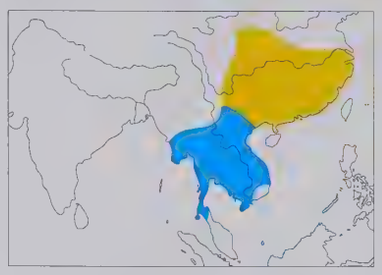
Genus *PERICROCOTUS* Boie, 1826

71. **Rosy Minivet**

Pericrocotus roseus

French: Minivet rose **German**: Rosenmennigvogel **Spanish**: Minivet Rosado

Taxonomy. *Muscicapa rosea* Vieillot, 1818, Bengal, India.
Forms a superspecies, and sometimes considered conspecific, with *P. cantonensis* and *P. divaricatus*. Is, however, very distinct from latter morphologically and differs also in moult and migration strategies. Apparently interbreeds with *P. cantonensis* in S China (S Guangdong), where a small, possibly now stable, population with mixed characters occurs in Xijiang Valley (this population was initially described as a separate species, *P. stanfordi*, and subsequently often regarded as a race of present species); no sign that the two hybridize in region where ranges closely approach each other or overlap elsewhere in S China, and zone of occurrence of "*stanfordi*" is sufficiently restricted to suggest that the parent forms now behave as separate species; further study required. Monotypic.
Distribution. N Pakistan E to NE India (E to Assam, Manipur and Nagaland), S China (SW Sichuan, W, S & SE Yunnan, Guizhou, Guangxi, SW Guangdong), Myanmar (S to N Tenasserim) and NW Vietnam (Tonkin); non-breeding S to C India and SE Asia (including Thailand, Laos and S Vietnam).



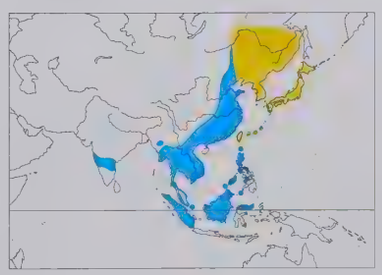
Descriptive notes. 18–20 cm; 14–19 g. Male has whitish forehead, supraloral stripe and eyelids, black lores, pale grey face to ear-coverts; crown to upper back and scapulars brownish-grey to grey, lower back to uppertail-coverts tending to pale rosy, uppertail-coverts tipped vermilion (with age, red of rump and uppertail-coverts may become brighter and upperparts more uniformly grey); wings greyish-black, greater upperwing-coverts tipped vermilion, merging into bright vermilion basal bands on remiges, these running obliquely across wing (extending farther along primaries than along secondaries), distal outer webs of tertials and inner secondaries vermilion; central pair of rectrices black-brown, second pair vermilion on outer web, remainder largely vermilion; chin and throat white, washed pink, underparts (including axillaries and underwing-coverts) pink; hybrid ("*stanfordi*") has pale pink forecrown, often pinkish on outer rectrices and wing markings, reddish tinge on rump, pink tinge on underparts; iris dark brown; bill and legs black. Differs from other red species of genus in lack of black on head, chin and throat, and pink (not red) underparts. Female is similar in pattern to male, but upperparts olive-tinged grey, back to uppertail-coverts often paler olive-yellow with yellower feather tips, secondary coverts tipped and edged yellow; wing flash also yellow, tail predominantly yellow; underparts dull yellow; hybrid ("*stanfordi*") has yellow wing markings, yellow in tail, yellow tinge on uppertail-coverts. Juvenile resembles female, but more brownish, with pale yellowish feather tips on head and upperparts, obscure dark scaling or mottling on breast; immature like female. Voice. Has a whirring trill (Thailand), a squeaky, whistling "whiririri-whiririri-whiririri" (India), and a twitter followed by longer, upslurred whistle (Assam).
Habitat. Inhabits many different types of forest, including broadleaf evergreen, deciduous and pine (*Pinus*), but also woodland, wooded valleys and gardens; sometimes occurs in towns. From 300 m to 1800 m. Migrants typically winter in slope forests (evergreen and deciduous), ranging out below hills to groves and clumps of woodland, and into plains-level cultivation with scattered trees.
Food and Feeding. Insects and other small arthropods. Commonly recorded in pairs, but often occurs in flocks in non-breeding season. Forages in canopy and subcanopy foliage; less active than other minivets.
Breeding. Apr–Jun in India; Apr in Myanmar. Nest built mainly by female, accompanied by male, a small, neat, deepish cup of roots, twigs, grass stems, lichens and cobwebs, placed 3–10 m above ground on horizontal tree branch. Eggs 2–4. No other information.
Movements. Resident and partial migrant. Migrants present in breeding areas mainly Apr–Oct; some possibly resident in Himalayas and NE India. Passage recorded in NE India (S Assam hills) and Bangladesh. Hybrid population ("*stanfordi*") breeding along R Xijiang in S China (S Guangdong) occurs on migration and in winter in E Thailand and S Laos. Vagrants recorded in S peninsular Thailand (five records, Dec) and Hong Kong.
Status and Conservation. Not globally threatened. Fairly common to common in Myanmar and China. Generally rare in Indian Subcontinent; local and uncommon in W Himalayas, rare and very local in Pakistan, rare in Bhutan; rare in Royal Chitwan National Park, in Nepal; occurs in Dibru-Saikhowa National Park, in NE India. Reported occurrence in E Afghanistan uncorroborated. In non-breeding season, fairly common visitor in Thailand, Laos and Cochinchina; occurs in Khao Yai National Park, in Thailand.
Bibliography. Ali & Ripley (1996), Cheng Tsohsin (1987), Deignan (1945), Dickinson & Dekker (2002a), Duckworth *et al.* (2002), Eames & Ericson (1996), Étchécopar & Hüe (1983), Grimmett *et al.* (1998), Hawa (1985), Herklots (1967), Inskipp & Inskipp (1991), Inskipp *et al.* (1996), Lekagul & Round (1991), MacKinnon & Phillipps (2000), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Ripley (1982), Roberts (1992), Robson (2000), Smythies (1986), Wells (2005), Zheng Guangmei & Zhang Cizu (2002).

72. **Swinhoe's Minivet**

Pericrocotus cantonensis

French: Minivet de Swinhoe **German**: Fahlbürzel-Mennigvogel **Spanish**: Minivet de Swinhoe
Other common names: Brown-rumped/Canton Minivet

Taxonomy. *Pericrocotus cantonensis* Swinhoe, 1861, Guangzhou (Canton), China.
Forms a superspecies with *P. roseus* and *P. divaricatus*. Often considered conspecific with former, primarily because the two apparently interbreed in S China (S Guangdong), where a small, possibly now stable, population with mixed characters occurs in Xijiang Valley (this population initially described as a separate species, *P. stanfordi*, and subsequently often regarded as a race of *P. roseus*); on other hand, no sign of hybridization where ranges closely approach each other or overlap elsewhere in S China, and zone of occurrence of "*stanfordi*" is sufficiently restricted to suggest that the parent forms now behave as separate species; further study required. Monotypic.
Distribution. Breeds C, S & SE China from SE Gansu and S Shaanxi E to S Jiangsu, S to S Guizhou, Guangxi, Guangdong and Fujian; non-breeding S China (Yunnan), S Myanmar (Tenasserim), Thailand (S to Trang, including Phuket I), Laos, Cambodia and S Vietnam.



Descriptive notes. 18–19 cm. Male has black lores, charcoal-grey region from mid-crown and rear of eye across ear-coverts to hindcrown and nape; forecrown and rest of head side white, including narrow projection at side of neck; mantle to back, and lesser and median upperwing-coverts, grey; rump and uppertail-coverts clay-buff; greater coverts, primary coverts and remiges blackish, white (usually tinged yellowish-buff) spot on inner webs of primaries P7–P1 and extending on to both webs of secondaries (visible in flight, usually not on folded wing); rectrices dark brown, outer five feathers with increasing amounts of white from tip inwards; white below, tinged vinous and washed ashy grey on breast and flanks; underwing-coverts greyish-white; hybrid ("*stanfordi*") has pale pink forecrown, often pinkish on outer rectrices and wing markings, reddish tinge on rump, pink tinge on underparts; iris dark brown; bill and legs black. Distinguished from similar *P. divaricatus* by grey (not black) on rear of head, white of forehead more extensive (to behind eye), brown-tinged upperparts with brownish rump, usually less visible wing patch, vinous-brown wash below. Female differs from male in having dark grey of head and nape replaced with paler grey, upper forehead and forecrown also grey, wing flash larger, including narrow white edges of tertials and inner secondaries, and spot extending to outer webs of P1–P5 (yellowish patch on closed wing), entirely off-white underparts; hybrid ("*stanfordi*") has yellow wing markings, yellow in tail, yellow tinge on uppertail-coverts. Juvenile undescribed; immature like female, but top of head more uniform grey, rump and uppertail-coverts tipped grey-white and barred darker, tertials and inner secondaries broadly tipped and edged white, outer secondaries edged white, throat side, half-collar, breast and flanks faintly barred grey. Voice. Inadequately described; metallic trill, flight call similar to that of *P. divaricatus*.
Habitat. Broadleaf evergreen forest, pine (*Pinus*) forest, deciduous forest, forest edge, open woodland; to 1200 m.
Food and Feeding. Details of diet not documented; probably similar to *P. roseus*. Forages in canopy; often in cohesive parties in winter.
Breeding. No information.
Movements. Migratory; spends winter months S & W of breeding range. Recorded on passage in S & SE China, and Cambodia. Present in peninsular Thailand mid–Dec to late Mar. Several sight records from NE Bangladesh require confirmation.
Status and Conservation. Not globally threatened. Formerly considered Near-threatened. Not well known; apparently locally common in S China. Uncommon in non-breeding range in SE Asia; locally uncommon to sparse in S Thailand, where regarded as bordering on "Near-threatened" because of loss of possible forest habitat.
Bibliography. Carey *et al.* (2001), Cheng Tsohsin (1987, 2002), Collar *et al.* (1994), Deignan (1945), Delacour (1951a), Dickinson & Dekker (2002a), Duckworth (1996), Duckworth *et al.* (2002), Étchécopar & Hüe (1983), Kazmierczak (2000), Lekagul & Round (1991), MacKinnon & Phillipps (2000), Medway & Wells (1976), Meyer de Schauensee (1984), Nguyen Cu *et al.* (2000), Rasmussen & Anderton (2005), Robson (2000), Round (2000a), Smythies (1986), Wells (2005), Zheng Guangmei & Zhang Cizu (2002).

73. **Ashy Minivet**

Pericrocotus divaricatus

French: Minivet cendré **German**: Graumennigvogel **Spanish**: Minivet Ceniciento
Other common names: Ryukyu Minivet (*tegimae*)

Taxonomy. *Lanius divaricatus* Raffles, 1822, Singapore.
Forms a superspecies with *P. roseus* and *P. cantonensis*. Closely related to former, and sometimes considered conspecific, but very distinct morphologically and differs also in moult and migration strategies. Dark race *tegimae* sometimes regarded as a separate species, but greater colour saturation is common among Ryukyu forms of Japanese bird species. Two subspecies recognized.
Subspecies and Distribution.
P. d. divaricatus (Raffles, 1822) – breeds SE Siberia (S from C Amurland), NE China (mainly Nei Mongol, Heilongjiang and Jilin), Korea and Japan, possibly also Taiwan; non-breeding mainly SE Asia, Greater Sundas and Philippines, also regularly India.
P. d. tegimae Stejneger, 1887 – Tokara Is and Ryukyu Is; recent breeding recorded also S Japan (S Kyushu).

Descriptive notes. 18 cm; average 21·6 g. Male nominate race has white forecrown, narrow black forehead band, black from lores to behind eye, across ear-coverts and extending over rear crown and nape; rest of head side and narrow half-collar at neck side white; upperparts, including lesser and median upperwing-coverts, uniform steel-grey; greater coverts and remiges sooty black, greater coverts tipped and edged steel-grey, outer webs of tertials and inner secondaries steel-grey, white spot on inner webs of P8–P1, on outer webs of P5–P1 and on both webs of secondaries (forming visible patch on closed wing); central pair of rectrices black, oth-

On following pages: 74. Small Minivet (*Pericrocotus cinnamomeus*); 75. Fiery Minivet (*Pericrocotus igneus*); 76. Flores Minivet (*Pericrocotus lansbergei*); 77. White-bellied Minivet (*Pericrocotus erythropygius*).

ers black with broad white tips; chin, throat and underparts white, underwing-coverts mottled grey and white; iris brown; bill and legs black. Differs from *P. cantonensis* in having rear head black, white forehead patch not extending behind eye, entire upperparts pure grey, visible wing patch, entirely white underparts. Female is like male, but black on head replaced by grey (except on lores and forehead), underparts duller white. Juvenile has more sooty upperparts with white feather fringes; immature like female, but greater coverts tipped white, tertials and inner secondaries boldly tipped and edged white, breast side and flanks finely and obscurely barred pale grey. Race *tegimae* is smaller than nominate, male much darker on upperparts, with much narrower white band on forecrown, upper breast ashy grey. Voice. Has metallic, jingling trill; flight call a rather unmelodious ascending "tchu-de tchu-dee-dee tchu-dee-dee".

Habitat. Evergreen and deciduous forests, secondary growth, woodland and areas with scattered trees; also mangroves, mixed peatswamp-forest, beach vegetation, casuarinas (*Casuarina*), plantations, open country, and even in towns, especially on passage and in winter. May occur in virtually any tree/open-area ecotone having scattered suitable cover. Sea-level to 1300 m; to 1600 m in Japan.

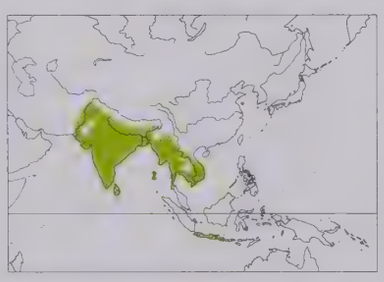
Food and Feeding. Eats mainly small invertebrates, including caterpillars (Lepidoptera) and, especially, flying insects, but no documented details. Forages in treetops, usually at outer edge of canopy; gleans larvae from leaves and branches, and catches adult insects in flight. Often occurs in flocks, especially in winter quarters; commonly joins mixed-species flocks in winter.

Breeding. Breeds May–Jun in Siberia; May–Jul in Japan, but in Ryukyus (race *tegimae*) nest-building from early Mar. Nest built by female, accompanied by and sometimes assisted by male, a cup of grass stems, cedar needles and lichens, often bound with cobwebs, placed 7–8 m above ground, in Ryukyus (race *tegimae*) occasionally to 11·5 m, in fork of horizontal tree branch. Eggs 4–5, rarely up to 7; incubation 17–18 days; no information on nestling period.

Movements. Race *tegimae* resident, with some local wandering. Nominate race a long-distance migrant, present on breeding grounds May–Sept in Siberia and Apr–Sept in Japan; migrates through Manchuria and Korea, Japan, Ryukyus, E China, Taiwan, recorded on passage also N Vietnam (E Tonkin) and Cambodia. Commonly migrates during day, also at night; passage recorded Hong Kong Mar–Apr and Sept–Oct. Main non-breeding grounds in SE Asia (mostly S parts), Greater Sundas and Philippines; occurs in Peninsular Malaysia and Philippines Sept–Apr, and recorded in Sumatra mid–Oct to late Jan. Regular but scarce non-breeding visitor to India, especially C peninsula, W Khandesh and Bombay; vagrant to C & SE Bangladesh, Andaman Is; one Sept record from N Sulawesi.

Status and Conservation. Not globally threatened. Race *tegimae*, often treated as a full species, is a restricted-range taxon: present in Nansei Shoto EBA. Fairly common in much of Ryukyu Is. Nominate race fairly common in China; fairly common but local in Japan; no information on status in SE Siberia, but formerly common there. In non-breeding season, uncommon to locally common in SE Asia and uncommon and sporadic in Philippines; few records Sumatra; occurs in several protected areas, e.g. Kaeng Krachan National Park, in Thailand, and Nam Bai Cat Tien National Park, in Vietnam.

Bibliography. Ali & Ripley (1996), Brazil (1991), Cheng Tsohsin (1987), Coates & Bishop (1997), Danielsen *et al.* (1994), Dementiev *et al.* (1969), Dickinson *et al.* (1991), Étchécopar & Hüe (1983), Flint *et al.* (1984), Grimmett *et al.* (1998), Herklots (1967), Inskipp *et al.* (1996), Jeyarajasingam & Pearson (1999), Kennedy *et al.* (2000), Lekagul & Round (1991), MacKinnon & Phillipps (1993, 2000), van Marle & Voous (1988), Medway & Wells (1976), Morioka (2000), Navarro (1965), Pittie & Poddar (1998), Prys-Jones (1991), Rabor (1977), Rasmussen & Anderton (2005), Ripley (1982), Robertson (1991), Santharam (1988), Smythies (1999), Stresemann & Stresemann (1972, 1973), Temme (1973), Tsai Hangyeh (1985), Vaurie (1959), Wells (2005), White & Bruce (1986), Zheng Guangmei & Zhang Cizu (2002).



74. Small Minivet

Pericrocotus cinnamomeus

French: Minivet oranor **German**: Zwergmennigvogel **Spanish**: Minivet Chico
Other common names: Little/Lesser Minivet

Taxonomy. [*Motacilla*] *cinnamomea* Linnaeus, 1766, Sri Lanka.
Forms a superspecies, and sometimes considered conspecific, with *P. igneus* and *P. lansbergei*. Relationship with former not fully resolved; no evidence of interbreeding (except for a single, purportedly intermediate specimen) where their ranges meet, in peninsular Thailand, and different habitat preferences may prevent direct contact between them. Isolated race *saturatus* possibly represents a different species, primarily on grounds of zoogeography. Race *peregrinus* intergrades with *pallidus* and *vividus* in N Indian Subcontinent. Race *separatus* possibly better treated as synonym of *vividus*, as its supposedly large bill may be individually variable, rather than diagnostic. It has been suggested that birds from Andaman Is may merit treatment as a separate race, for which the name *osmastoni* was recently proposed, but further study required. Nine subspecies currently recognized.

Subspecies and Distribution.
P. c. pallidus Stuart Baker, 1920 – Pakistan (Indus Valley) and NW India.
P. c. peregrinus (Linnaeus, 1766) – NW Himalayas and N India (Punjab S to N Madhya Pradesh, E to Bihar and N Orissa).
P. c. cinnamomeus (Linnaeus, 1766) – C & SE India (S from S Rajasthan, Madhya Pradesh and S Orissa) and Sri Lanka.
P. c. malabaricus (J. F. Gmelin, 1789) – SW India (Karnataka, S from Belgaum, S to Kerala).
P. c. vividus Stuart Baker, 1920 – C Himalayas, E India (West Bengal, Assam), Bangladesh, W & C Myanmar, SW & C Thailand, and Andaman Is.
P. c. thai Deignan, 1947 – NE Myanmar, N & NE Thailand, Laos.
P. c. sacerdos Riley, 1940 – Cambodia and S Vietnam.
P. c. separatus Deignan, 1947 – SE Myanmar and NW peninsular Thailand.
P. c. saturatus Stuart Baker, 1920 – Java and Bali.

Descriptive notes. 16 cm; 6–12 g. Male nominate race is dark grey on lores, face to above eye, ear-coverts and chin to lower throat; forehead to back and scapulars paler grey, rump and uppertail-coverts rich reddish-orange; upperwing sooty black, greater coverts tipped orange, remiges with yellow flash on primaries, pale orange on secondaries; innermost two rectrices sooty black, outer four mainly pale orange; breast bright orange, shading to yellow on belly and creamy yellow on undertail-coverts; underwing-coverts pale yellow; iris dark brown; bill and legs black. Distinguished from congeners by combination of smaller size, grey head and upperparts (with darker face), and orange and yellow underparts. Female differs from male in having whitish forehead, narrow pale supercilium from base of bill to eye, white eyelids, paler grey crown to back and scapulars, duller orange rump (tinged olive), wing markings all yellow, much reduced on greater coverts, throat whitish, underparts greyish-white with yellow suffusion. Juvenile is like female, but cap to back, and lesser and median upperwing-coverts, browner, with whitish feather edges (broadest on coverts), tertials edged and tipped whitish; immature like female, but young male lacks supercilium. Races vary mainly in depth of coloration and extent of bright colours: *pallidus* is much paler above, has red below restricted to narrow band below throat, upper flanks washed yellowish, rest of underparts white, female also very pale, throat and underparts entirely white or whitish; *peregrinus* is intermediate between previous and nominate, rather dark grey above, throat blackish, mostly orange below, vent white, female strongly washed yellow below; *vividus* is darker above than last, throat blackish-grey, breast and flanks bright reddish-orange, belly and vent yellow; *malabaricus* is darker and more richly coloured than nominate, dark slaty grey above, with glossy black throat, deep reddish-orange below, orange-yellow on belly, female dark grey-brown above and extensively yellow on lower underparts; *thai* resembles previous, but male throat dark grey, not black; *sacerdos* has orange areas redder and more vivid; *separatus* female has less yellow on underparts that previous two; *saturatus* is darkest race. Voice. Contact call a thin, drawn-out whistle, "tswee-eet" and "swee swee", frequently repeated.

Habitat. Forest, woodland, mangrove forest, thorn-forest, strand woodland, casuarinas (*Casuarina*), scrub, orchards and other cultivated lands; sometimes occurs around villages. Prefers more open wooded habitats than those occupied by most congeners. Lowlands, to 1600 m.

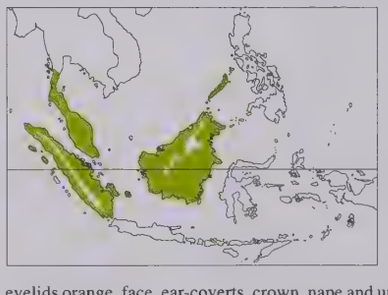
Food and Feeding. Takes moths and caterpillars (Lepidoptera) and other insects, including beetles (Coleoptera) and cicadas (Cicadidae). Forages in parties in canopy; often joins mixed-species parties. Gleans leaves, and makes short sallies to catch flying prey.

Breeding. Feb–Nov, mainly Apr–Sept; may be double-brooded in some areas. Nest built by both sexes, a small, neat cup of fine twigs, grass stems, lichen, dead leaves or bark, lined with rootlets and bound with cobwebs, attached to tree branch or fork up to 12 m above ground. Eggs 2–4; incubation by female; no information on incubation and fledging periods.

Movements. None known.

Status and Conservation. Not globally threatened. Very common in suitable habitat over Indian Subcontinent; widespread and locally common in Bangladesh, but local in Pakistan and rare in Bhutan. Common in most of SE Asia, but regarded as "Vulnerable" in peninsular Thailand because of lack of records inland of mangrove zone. Uncommon in Java and Bali. A 19th-century specimen from Borneo is considered questionable. Occurs in several protected areas, including e.g. Royal Chitwan National Park, in Nepal, and Nagarhole and Keoladeo Ghana (Bharatpur) National Parks, in India.

Bibliography. Abdulali (1975), Ali (1969), Ali & Ripley (1996), Andrew (1985), van Balen (1999), Deignan (1945, 1947, 1963), Dickinson & Dekker (2002a), Futehally (1984), Grimmett *et al.* (1998), Hellebrekers & Hoogerwerf (1967), Inskipp & Inskipp (1991), Jerdon (1862), Jones *et al.* (1998), King *et al.* (1975), Kotagama (1985a, 1985b), Lekagul & Round (1991), MacKinnon & Phillipps (1993), Mittal & Vijay (1990), Mukherjee (1995), Neelakantan (1950), Ranasingh (1977), Rane (1984), Rasmussen & Anderton (2005), Ripley (1982), Roberts (1992), Robson (2000), Round (1988), Seneviratne (1976), Smythies (1986), Stuart Baker (1929), Van Tyne & Koelz (1936), Wells (2005).



75. Fiery Minivet

Pericrocotus igneus

French: Minivet flamboyant **German**: Feuermennigvogel **Spanish**: Minivet Encendido

Taxonomy. *P[ericrocotus] igneus* Blyth, 1846, Melaka, Peninsular Malaysia.
Forms a superspecies with *P. cinnamomeus* and *P. lansbergei*. Sometimes treated as a race of *P. cinnamomeus*, and relationship between the two not fully resolved; no evidence of interbreeding (except for a single, purportedly intermediate specimen) where their ranges meet, in peninsular Thailand, and different habitat preferences may prevent direct contact between them. Two subspecies recognized.

Subspecies and Distribution.
P. i. igneus Blyth, 1846 – S Myanmar (Tenasserim), S Thailand, Peninsular Malaysia, Sumatra (including Nias I, Bangka and Belitung), Borneo and SW Philippines (Palawan).
P. i. trophis Oberholser, 1912 – Simeulue I, off W Sumatra.

Descriptive notes. 15–16·5 cm; 14–16 g. Nominate male has head, mantle and scapulars glossy black, back to uppertail-coverts rich orange-red; wings glossy black, outer webs of secondary coverts broadly edged orange-red, wingpanel formed by orange-red on outer webs of P6–P1 and yellow on inner webs of P9–P1; central two rectrices black, others orange-red; underparts rich orange-red, underwing-coverts yellow; iris dark brown; bill and legs black. Distinguished from very similar *P. flammeus*, *P. ethologus* and *P. brevirostris* by smaller size, more orange (less red) coloration, and smaller wing patch. Female has forehead, lores and eyelids orange, face, ear-coverts, crown, nape and upperparts to back lead-grey, rump and uppertail-coverts as in male, with narrow olive band between back and rump, upperwing grey, wingpanel paler orange and less extensive than on male, underparts yellow; differs from e.g. *P. flammeus* in combination of yellow underparts, orange-red rump and outer tail and orange-yellow wingpanel. Juvenile has head, upperparts and upperwings sooty brown with fine yellowish feather fringes, uppertail-coverts orange, primary coverts and remiges sooty black, tertials tipped yellow, wingpanel yellow to pale orange, throat and underparts off-white, faintly barred ash-brown; immature similar to adult female. Race *trophis* differs from nominate essentially in larger size. Voice. Rising "swee-eet" call.

Habitat. Forest and forest edges, in mature and well-regenerated vegetation; also in woodland, old plantations, very locally in casuarina (*Casuarina*) scrub, dry beach forest, occasionally wooded gardens close to forest. Normally in lowlands, to 1200 m.

Food and Feeding. Eats small arthropods, including ants (Formicidae) and small beetles (Coleoptera). Forages in canopy, gleaning from foliage; visits fig trees (*Ficus*), apparently to feed on insects attracted to ripening fruit. Often occurs in groups.

Breeding. Breeds in Apr-May (start of rains), and dependent fledglings recorded also Jun–Jul, in Malay Peninsula; in Dec (dry season) in Philippines (Palawan). Nest a shallow, neat small cup of fine twigs and other fibres, bound with cobwebs, decorated with lichen and bark, placed on fork of tree branch. Eggs 2. No other details.

Movements. None recorded.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Regular and more or less common in S Myanmar and Peninsular Malaysia, but uncommon in Thailand; extinct in Singapore. Current status in Borneo uncertain; was formerly uncommon. Locally quite common in Sumatra and on Palawan in 1980s and 1990s. Forest destruction in Sundaic lowlands of Indonesia is very extensive and continuing, and expected that all primary forms will have disappeared by 2010; situation in Thailand and Peninsular Malaysia similar. This species, however, can utilize submontane slopes, where forest destruction has been less severe, and it also inhabits secondary growth; it may, therefore, not be immediately threatened. Its stability after isolation on major slopes is not assured, but in production forest it has the advantage of being a high-canopy, gap-crossing species. Occurs in several protected areas, including Taman Negara National Park, in Peninsular Malaysia, Way Kambas National Park, in Sumatra, Danum Valley Conservation Area, in Borneo, and St Paul Subterranean River National Park, in Philippines.

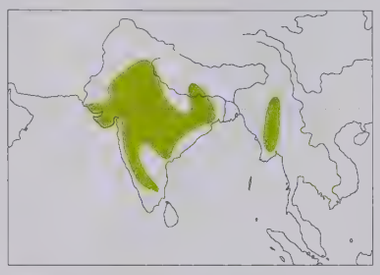
76. Flores Minivet

Pericrocotus lansbergei

French: Minivet de Sumbawa **German**: Floresmennigvogel **Spanish**: Minivet de Flores
Other common names: Little/Orange-breasted/Sumbawa Minivet

Taxonomy. *Pericrocotus Lansbergei* Büttikofer, 1886, Bima, Sumbawa Island, Lesser Sundas.
Forms a superspecies with *P. cinnamomeus* and *P. igneus*; sometimes regarded as conspecific with former. Monotypic.
Distribution. Sumbawa and Flores, in W Lesser Sundas.

Descriptive notes. 16 cm. Male has glossy black head, mantle, scapulars and upper breast, orange-red rump and uppertail-coverts; upperwing blackish, orange-red panel on median and greater wing-coverts and broadly on bases of remiges; central pair of tail feathers black, remainder orange-red; breast and upper flanks orange-red, rest of underparts plain white; iris dark brown; bill and legs black. Distinguished from *P. cinnamomeus* by darker head and back, no yellow in wing, white abdomen; from *P. flammeus* by smaller size, white abdomen. Female differs from male in having black areas above replaced by smoky-brown, dull yellowish rump, smaller wing patch, entirely greyish-white to white throat and underparts. Juvenile undescribed; immature resembles female. Voice. Has quiet trilling calls.
Habitat. Open, parkland-type forest with sparse understorey; also primary forest, tall secondary and riverine forest, and woodland. Sea-level to 1150 m on Sumbawa and to 1820 m on Flores; mainly below 500 m.
Food and Feeding. Eats small arthropods. Usually forages in pairs or small groups; often joins mixed-species flocks. Forages by gleaning and hover-gleaning from horizontal perches in middle storey.
Breeding. Breeds Apr–Jun. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Northern Nusa Tenggara EBA. Considered to be generally uncommon, but can be locally moderately common.



Bibliography. Andrew (1992), Butchart *et al.* (1996), Coates & Bishop (1997), Collar & Andrew (1988), Dickinson *et al.* (2002a), Inskipp *et al.* (1996), Johnstone *et al.* (1996), Strange (2001), Sujatnika *et al.* (1995), Trainor (2002a), White & Bruce (1986).

77. White-bellied Minivet

Pericrocotus erythropygius

French: Minivet à ventre blanc **Spanish**: Minivet Ventriblanco
German: Weißbauch-Mennigvogel
Other common names: Jerdon's Minivet

Taxonomy. *M[uscicapa] erythropygia* Jerdon, 1840, Ajanta Hills, Aurangabad District, Hyderabad, India.
Has been proposed that distinctive race *albifrons* be elevated to species rank. Two subspecies recognized.
Subspecies and Distribution.
P. e. erythropygius (Jerdon, 1840) – W & C India (mainly Gujarat and from C Rajasthan and W Haryana E to Bihar and S to C Maharashtra and Andhra Pradesh).
P. e. albifrons Jerdon, 1862 – plains of C Myanmar.

Descriptive notes. 15–16·5 cm. Distinctive minivet, with plumage somewhat reminiscent of that of a stonechat (*Saxicola*). Male nominate race has glossy blue-black head, mantle, back and scapulars, white rump with deep orange centre, black uppertail-coverts; upperwing black, greater upperwing-coverts pure white, primaries narrowly edged white-brown, tertials broadly edged white; tail black, outer four feather pairs tipped white, white becoming broader outwards, outermost rectrix mostly white; underparts (including underwing-coverts) white, with orange breast patch; iris dark brown; bill and legs black. Easily distinguished from all congeners by black-and-white plumage with orange on rump and breast. Female has black areas of male replaced by grey-brown, pale forehead and supraloral line, grey-brown ear-coverts, white throat and underparts, tinged ashy on breast; tail as male. Juvenile is like female, but crown, mantle and back scaled or barred whitish, upperwing-coverts tipped white, some dark spots on side of breast; immature like female, but not fully described. Race *albifrons* differs from nominate in having white forehead and supercilium, white throat, cheeks and neck side, more white in wing (edges of primary coverts white, tertials almost all white), white tips on all rectrices, eye brownish. Voice. Sweet, high-pitched notes, "thi", "tuee", "chi", "tschi", "tchu-it" and similar; contact call a soft "tchip".
Habitat. Open, dry scrub, grassland, savanna, dry cultivation with scrub and scattered trees, hedgerows and thorn-scrub; occurs in drier areas, on rocky scrub-covered slopes, sometimes in semi-desert.
Food and Feeding. Food mainly insects, including grasshoppers (Orthoptera), also spiders (Araneae). Occurs in pairs or small parties. Less arboreal than its congeners; perches on low bushes, long grass and even on the ground. Flies down to catch prey; hovers over grass and drops on to prey; gleans from leaves and weed stems; also catches insects in the air.
Breeding. Breeds in Jun–Oct in India and Jul in Myanmar. Nest built by both sexes, a small, neat cup of grass and fibres, lined with flowering grasses, bound with cobwebs and ornamented with bark or vegetable down on outside, placed 1–2 m above ground in vertical or horizontal fork of branch of bush or small tree. Eggs 3; both sexes incubate and care for young; no information on incubation and fledging periods.
Movements. Apparently makes erratic movements outside breeding season in India, where scattered records E to West Bengal and S to Kerala; also recorded as very scarce vagrant in S Pakistan.
Status and Conservation. Not globally threatened. Very local and uncommon to rare in India; occurs in Mudumalai National Park. Uncommon to rare in Myanmar, where formerly regarded as common.

Bibliography. Ali & Ripley (1996), Chakravarthy & Purna Chandra Tejasvi (1992), Collar & Andrew (1988), Daniels (1997), Grimmett & Inskipp (2003), Grimmett *et al.* (1998), Inskipp *et al.* (1996), Jerdon (1862), Karthikeyan (1992), Kazmierczak (2000), Mukherjee (1995), Rasmussen & Anderton (2005), Ripley (1982), Roberts (1992), Robson (2000), Saha & Dasgupta (1992), Smythies (1986).

PLATE 12

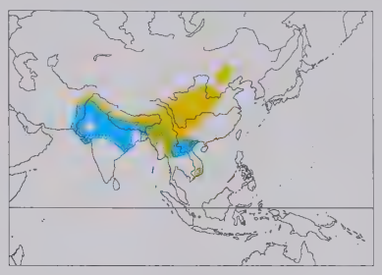
78. Grey-chinned Minivet

Pericrocotus solaris

French: Minivet mandarin **German**: Graukehl-Mennigvogel **Spanish**: Minivet Gorgigrís
Other common names: Mountain/Yellow-throated Minivet; Grey-throated Minivet (*cinereigula*)

Taxonomy. *P[ericrocotus] solaris* Blyth, 1846, Darjeeling, West Bengal, India.
Distinctive race *montanus* sometimes treated as a separate species, a possibility that deserves further study. Eight subspecies recognized.
Subspecies and Distribution.
P. s. solaris Blyth, 1846 – C & E Himalayas (WC Nepal E to Assam) and N & W Myanmar.
P. s. rubrolimbatus Salvadori, 1887 – E & SE Myanmar and N Thailand.
P. s. montpellieri La Touche, 1922 – S China (N Yunnan).
P. s. griseogularis Gould, 1863 – SE China (Guizhou, N Guangxi, C & S Hunan, Guangdong, NW & E Fujian), Taiwan, Hainan, NE Laos and N Vietnam.
P. s. deignani Riley, 1940 – S Laos and C Vietnam (C & S Annam).
P. s. nassovicus Deignan, 1938 – SE Thailand and S Cambodia.
P. s. montanus Salvadori, 1879 – Peninsular Malaysia and W Sumatra.
P. s. cinereigula Sharpe, 1889 – N Borneo.



Descriptive notes. 17–19 cm; 11–17 g. Male nominate race has top of head and upperparts leaden black, ear-coverts and cheeks ashy grey; upperwing-coverts and remiges blackish, greater coverts tipped scarlet, merging into vermilion band across bases of primaries P1–P7; central pair of rectrices black, edged vermilion near tip, other rectrices vermilion with black bases; chin light grey, throat orange; underparts orange-scarlet, thighs grey-black, underwing-coverts orange; iris dark brown; bill and legs black. Distinguished from other red minivets mainly by grey chin and ear-coverts, and by bright colours being more orange than red. Female has black areas replaced by dark grey-brown, lower back, rump and uppertail-coverts greenish-yellow, red in wings replaced by yellow, primaries edged whitish towards tips, face side light grey, throat greyish-white, shading into yellow on breast, rest of underparts bright yellow. Juvenile is like female but darker above, with yellow scales or bars, inner secondaries and tertials edged yellow; immature like adult female, but back to uppertail-coverts barred or uniform yellow-olive. Race *montpellieri* male has dark olive mantle, olive-yellow rump, red uppertail-coverts; *rubrolimbatus* has whitish chin, orange-yellow wash on throat; *griseogularis* is tinged yellow-olive on throat and is redder on underparts than previous; *nassovicus* differs from last in having yellow-olive on throat darker, less contrasting, underparts more reddish-orange; *deignani* resembles previous, but crown and mantle slightly darker; *cinereigula* male has dark grey throat; *montanus* male is distinctive, has entire head glossy black, as well as mantle to scapulars, and is redder on wings and underparts. Voice. Thin, repeated "tswee-seet", a slurred "swirrrrirrit", and soft "trip" and "trii-ii" notes when foraging.
Habitat. Open forest, both broadleaf evergreen and moist deciduous forest, sometimes coniferous forest, and including short summit-growth; also forest edge, secondary growth (especially with large tree-ferns), sometimes wooded gardens. In mountains, mostly from 600 m to 3050 m; down to 300 m or lower in non-breeding season.
Food and Feeding. Takes small invertebrates, including termite alates (Isoptera). Groups often join mixed-species parties. Forages in canopy, mainly in terminal foliage. Gleans items; also makes aerial sallies after swarming termites.
Breeding. Breeds Feb–Apr in Malay Peninsula; Jun in Himalayas. Nest built by both sexes, a small cup of twigs, roots and grass stems (sometimes bryophytes), bound with cobwebs and camouflaged with lichens, placed 10–21 m above ground on exposed lateral bough or in horizontal fork of forest tree. Eggs 3; no information on incubation and fledging periods; young tended by both sexes.
Movements. Mainly resident; altitudinal movements in E Himalayas and elsewhere.
Status and Conservation. Not globally threatened. Scarce in Nepal; common in Bhutan; locally frequent in NE India. Common throughout range in China and Taiwan; common also in SE Asia, including Malay Peninsula (race *montanus*), where its habitat is still extensively secure, but few recent records of *montanus* from Sumatra. Current status in Borneo not known, but occurs in Mount Kinabalu National Park; formerly very common. Found in several other protected areas, e.g. Kaeng Krachan National Park, in Thailand.
Bibliography. Ali (1986), Ali & Ripley (1996), Ali *et al.* (1996), Cheng Tsohsin (1987), Deignan (1945, 1963), Dickinson & Dekker (2002a), Eames & Ericson (1996), Eames & Robson (1992), Étchécopar & Hüe (1983), Grimmett *et al.* (1998), Hawa (1985), Inskipp & Inskipp (1991), Jeyarajasingam & Pearson (1999), Lekagul & Round (1991), MacKinnon & Phillipps (1993, 2000), Madoc (1976), van Marle & Voous (1988), Medway & Wells (1976), Rasmussen & Anderton (2005), Ripley (1982), Robson (2000), Round (1988), Smythies (1986, 1999), Stepanyan (1995), Tsai Hangyeh (1985), Wells (2005), Zheng Guangmei & Zhang Cizu (2002).

79. Long-tailed Minivet

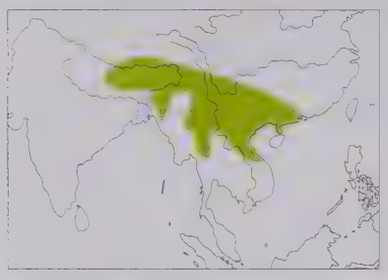
Pericrocotus ethologus

French: Minivet rouge **German**: Langschwanz-Mennigvogel **Spanish**: Minivet Colilargo
Other common names: Flame-coloured Minivet

Taxonomy. *Pericrocotus brevirostris ethologus* Bangs and J. C. Phillips, 1914, Hsien Shan, Hubei, China.
Was for long erroneously included within partly sympatric *P. brevirostris*. Putative race *cryptus* (described from Doi Pha Hom Pok, in N Thailand) considered indistinguishable from *ripponi*. Seven subspecies recognized.
Subspecies and Distribution.
P. e. favillaceus Bangs & J. C. Phillips, 1914 – breeds NE Afghanistan (Nuristan) and NW Himalayas (E to W Nepal); non-breeding S to S Pakistan and W India.
P. e. laetus Mayr, 1940 – E Nepal E to NE India (N & W Assam) and S China (SE Xizang).
P. e. ethologus Bangs & J. C. Phillips, 1914 – breeds NE India (E Assam), N Myanmar and C China (Hebei and S Shanxi S to SW Gansu, SE Qinghai, Yunnan and Guizhou); non-breeding N Thailand, N Laos, N Vietnam (Tonkin).
P. e. mariae Ripley, 1952 – NE India (SE Assam) and W Myanmar (Chin Hills).
P. e. yvettae Bangs, 1921 – NE Myanmar and S China (W & SW Yunnan).
P. e. ripponi Stuart Baker, 1924 – E Myanmar (S Shan, Karenni) and NW Thailand.
P. e. annamensis Robinson & Kloss, 1923 – SC Vietnam (S Annam).

Descriptive notes. 17·5–20·5 cm; 18 g. Male nominate race has head and upperparts to upper back black, glossed blue, lower back to uppertail-coverts scarlet; upperwing glossy black, greater coverts largely all scarlet, secondaries and tertials black, innermost 2–3 secondaries/outer tertials margined scarlet, inner primaries (P1–P7) with scarlet band across bases, longer on outer feathers, outermost primary edged pink-white; tertials narrowly edged whitish when fresh; tail relatively long, central two pairs of rectrices black, R2 with narrow red edge, outer four largely scarlet; upper throat dull black, lower throat and breast to undertail-coverts scarlet; underwing-coverts orange-chrome; iris dark brown; bill, legs and feet black. Distinguished with difficulty from other red-and-black minivets mainly by slim build, relatively long tail, distinctive pattern of wing patch, with second red line (along secondary/tertial edges); from *P. flammeus* by lack of red spot near tip of inner secondaries and tertials. Female has narrow yellowish band on forehead and above dusky lores, narrow white eyering, whitish cheeks, pale grey ear-coverts; greyish-olive upperparts, greyer on crown, with lower back to uppertail-coverts yellowish olive-green; red in wings replaced by yellow, but no yellow edges of tertials; red in tail replaced by yellow, with less colour on R2; chin and upper throat whitish, lower throat pale yellow, underparts yellow with faint olive wash. Juvenile is like female, but upperparts scaled yellowish, upperwing-coverts tipped yellowish-white, chin to lower breast whitish, throat side, breast and flanks spotted and barred grey-brown; immature like female, but male darker on upperparts and more orange on areas that are yellow in female, lacks coloured secondary/tertial edges. Races differ mainly in plumage of female: *yvettae* has greyer crown to mantle than nominate, with yellower forehead; *annamensis* is similar to previous, but yellow in plumage deeper and brighter, with orange tinge; *mariae* differs from last in having less of an orange tinge in yellow areas, male has larger wing patch; *ripponi* is intermediate between previous and nominate; *favillaceus* has cold grey upperparts and paler, lemon-yellow, underparts; *laetus* has more extensive and brighter yellow on upperparts, and orange tinge in yellow underparts. Voice. A sweet, rolling repeated "prrr'wi" and "prrr'i"; thin, sibilant "swii-swii swii-swii-swii".
Habitat. Wide range of open forest types, including broadleaf and pine (*Pinus*) forests, light forest and forest edge; occurs also (especially in winter) in largely deforested areas, groves, wooded cultivation and roadside avenues. Mountains at 900–3650 m, rarely to 3965 m; descends to 245 m in non-breeding season.
Food and Feeding. Eats chiefly insects, including orthopterans, hymenopterans, beetles (Coleoptera), flies (Diptera) and insect larvae, also spiders (Araneae); also takes buds of acacias (*Acacia*) and fruits. Forages chiefly in canopy; gleans, makes aerial sallies, and hovers in front of flowers. May form large flocks outside breeding season.
Breeding. Season Apr–Jun. Nest built by both sexes, a neat cup of grass stems, fine twigs, rootlets or moss, with cobweb and lichen on outside, attached to horizontal tree branch 5–24 m (usually above 15 m) above ground. Eggs 3–4; no information on incubation and fledging periods; young fed by both parents.
Movements. Nominate race mainly migratory, moves S to N parts of SE Asia (mainly N Thailand, N Laos, Tonkin) after breeding. Partially migratory also in NW of range (race *favillaceus*), moving S to C Pakistan (rarely, S to Sind) and W India (to Rajasthan). Seasonal altitudinal movements, with post-breeding descent to lower levels, including plains areas, also dispersive in winter. Arrives in high-altitude breeding areas in Afghanistan and Himalayas in Mar–Apr; absent from these areas Oct–Mar, descent to lower altitudes generally occurring Aug–Nov, reaching foothills by Sept and plains by Nov. Nepal breeders winter as far S in India as Madhya Pradesh and Orissa.
Status and Conservation. Not globally threatened. Common in Pakistan, N India, Nepal, Bhutan, Myanmar, Thailand and Vietnam (Annam); common in China. Uncommon to locally common non-breeding visitor in Myanmar, Thailand and E Tonkin, but scarce and local in Bangladesh. Status in Laos and W Tonkin unclear. Occurs in a number of protected areas.
Bibliography. Ali (1986), Ali & Ripley (1996), Ali *et al.* (1996), Bangs & Phillips (1914), Cheng Tsohsin (1987), Deignan (1945, 1963), Dharmakumarsinhji (1985), Dickinson & Dekker (2002a), Eames & Ericson (1996), Eames & Robson (1992), Étchécopar & Hüe (1983), Grimmett *et al.* (1998), Inskipp & Inskipp (1991), King *et al.* (1975), Lekagul & Round (1991), Liu Huanjin & Shen Shouyi (1989), MacKinnon & Phillipps (2000), Martens & Eck (1995), Mukherjee (1995), Norman & Sivasubramanian (1992), Rasmussen & Anderton (2005), Ripley (1982), Roberts (1992), Robson (2000), Round (1988), Smythies (1986), Vaurie (1959), Zheng Guangmei & Zhang Cizu (2002).

80. Short-billed Minivet



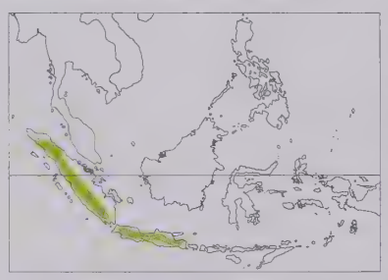
Pericrocotus brevirostris

French: Minivet à bec court **German**: Kurzschnabel-Mennigvogel **Spanish**: Minivet Piquicorto

Taxonomy. *Muscipeta brevirostris* Vigors, 1831, Himalayas = "probably Sikkim foothills".
Was for long erroneously considered to include partly sympatric *P. ethologus*. Race *affinis* sometimes synonymized with nominate, which possibly a preferable treatment, although some specimens identified as of former race are, in fact, referable to *P. ethologus*; further study required. Proposed race *pulcherrimus*, described from S Myanmar (Mulayit Taung, in Tenasserim), considered inseparable from *neglectus*, and *tonkinensis*, described from N Vietnam (Bac Kan, in Tonkin), indistinguishable from *anthoides*. Four subspecies recognized.
Subspecies and Distribution.
P. b. brevirostris (Vigors, 1831) – C & E Himalayas (in NE India extending S into W Assam) and S China (SE Xizang, NW Yunnan).
P. b. affinis (McClelland, 1840) – NE India (E Assam), N Myanmar and S China (Sichuan, W & SW Yunnan).

On following pages: 81. Sunda Minivet (*Pericrocotus miniatus*); 82. Scarlet Minivet (*Pericrocotus flammeus*).

P. b. neglectus Hume, 1877 – SE Myanmar and NW Thailand.
P. b. anthoides Stresemann, 1923 – S China (SE Yunnan, Guizhou, Guangxi, N Guangdong), Laos and N Vietnam.



Descriptive notes. 19–20 cm; 16–17 g. Male nominate race has head to upper breast, and mantle and scapulars, glossy blue-black, back to uppertail-coverts deep crimson; upperwing-coverts glossy black, greater coverts crimson, remiges black, basal half of primaries P1–P7 crimson; central pair of rectrices black, next pair crimson with black on basal half, outer three pairs crimson; underparts crimson, thighs blackish, underwing-coverts yellow-orange; iris dark brown; bill and legs black. Differs from *P. ethologus* in shorter tail with more extensive red, lack of red line along edges of inner secondaries/tertials; from *P. flammeus* in lack of red spot near tip of inner secondaries and tertials. Female has yellowish forehead, this colour extending to crown, yellow-washed greyish ear-coverts and cheeks, yellowish eyering; upperparts dull ashy grey, lower back to uppertail-coverts yellowish olive-green, crimson in wing and tail replaced by yellow; chin, throat and entire underparts yellow. Juvenile is like female, but upperparts scaled yellowish, upperwing-coverts tipped yellowish-white, side of throat, breast and flanks spotted and barred grey-brown, underparts less extensively yellow, more whitish; immature like female, but young male more orange-yellow on underparts and orange on wings and tail. Races differ mainly in plumage of female: *affinis* female has less yellow on head, more like *P. ethologus*; *neglectus* is smaller than nominate; *anthoides* female has chin and underparts duller yellow. Voice. Call a distinctive, thin, sweet, repeated whistled "tsuuuit"; dry "tup" as contact note.
Habitat. Open deciduous and evergreen forest, forest edge and secondary growth; also pine (*Pinus*) forest. In mountains at 900–2745 m; breeds at 1800 m and above.
Food and Feeding. Takes adult and larval arthropods; also buds. Usually occurs in pairs; often joins mixed-species foraging flocks. Forages among foliage. No further information.
Breeding. Breeds Mar–Apr. Nest a neat cup of moss and lichen, placed c. 10 m above ground on horizontal outer branch of tree. Eggs 3. No other information.
Movements. Descends to lower levels in winter.
Status and Conservation. Not globally threatened. Fairly common to locally common in Myanmar, NW Thailand, Laos and N Vietnam; uncommon in China; scarce in Himalayas. Generally much less numerous than *P. ethologus* where both species occur together. Status and ecology poorly known, because of past confusion with latter species. Occurs in several protected areas, e.g. Namdapha National Park, in India, and Doi Inthanon National Park, in Thailand.
Bibliography. Ali (1986), Ali & Ripley (1996), Cheng Tsohsin (1987), Deignan (1945), Dickinson & Dekker (2002a), Dodsworth (1910), Duckworth *et al.* (2002), Étchécopar & Hüe (1983), Grimmett *et al.* (1998), Heath (1989), Inskipp & Inskipp (1991), Lekagul & Round (1991), MacKinnon & Phillipps (2000), Mayr (1940), Rae (1934), Rasmussen & Anderton (2005), Ripley (1982), Robson (2000), Round (1988), Smythies (1986), Zheng Guangmei & Zhang Cizu (2002).

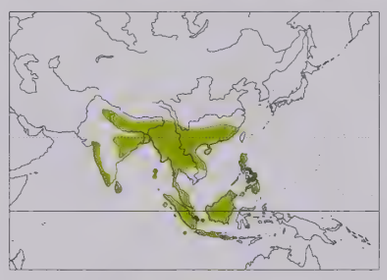
81. **Sunda Minivet**

Pericrocotus miniatus

French: Minivet vermillon **German**: Sundamennigvogel **Spanish**: Minivet de la Sonda

Taxonomy. *Muscicapa miniata* Temminck, 1822, Java.
Monotypic.
Distribution. Highlands of W Sumatra and Java.

Descriptive notes. 19 cm. Very long-tailed minivet, unique in having female plumage black and red, as male. Male has head and upperparts black, slightly glossed blue; lower back, rump and uppertail-coverts scarlet-vermilion; wings black, greater upperwing-coverts vermilion, innermost with black centres, primaries with broad vermilion band across both webs (only on inner webs of P7–P10); central pair of rectrices black, slightly edged and tipped vermilion, remainder vermilion with black bases; throat black, underparts scarlet-vermilion, underwing-coverts paler vermilion, thighs blackish, spotted pink; iris brown; bill and legs black. Distinguished from congeners by combination of black head, very long tail, and absence of red spot on inner secondaries. Female is similar to male, except that forehead, supercilium, face side, throat and entire underparts are rose-vermilion, mantle and lesser upperwing-coverts have dull crimson feather edges, greater coverts black, broadly tipped vermilion. Juvenile and immature undescribed. Voice. Hard, shrill "chee-chee-chee" and a protracted, loud "tsree-ee".
Habitat. Forest and forest edge, including moss forest; also cultivated lands, and pine (*Pinus*) plantations in Sumatra. In mountains, from 1200 m to 2700 m.
Food and Feeding. Food not documented; presumably mainly insects. Frequents canopy, occurring in parties and flocks; no information on foraging methods.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Sumatra and Peninsular Malaysia EBA and Java and Bali Forests EBA. Poorly known. Regarded as quite common in Java and locally common in Sumatra in 1980s and early 1990s. Rare in Gunung Gede-Pangrango National Park, in Java.
Bibliography. Andrew (1985, 1992), Hellebrekers & Hoogerwerf (1967), Holmes & Nash (1989), Inskipp *et al.* (1996), MacKinnon (1988), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Nijman & Sözer (1996), Sujatnika *et al.* (1995).



82. **Scarlet Minivet**

Pericrocotus flammeus

French: Grand Minivet **German**: Scharlachmennigvogel **Spanish**: Minivet Escarlata

Other common names: Indian/Flame/Orange Minivet

Taxonomy. *Muscicapa flammea* Forster, 1781, no locality = Sri Lanka.
Geographical variation complex and inadequately described, with many intermediate populations in SE Asia; modern review desirable. Race *speciosus* sometimes regarded as a separate species, on basis of its deep scarlet colour; if such treatment adopted, *fraterculus*, *andamanensis* and *semiruber* could perhaps be included as races of it. Race *nigroluteus* originally named *neglectus*, but latter name invalid, because preoccupied. Birds on Bohol (Philippines) of unconfirmed racial identity, presumed to belong with *leytensis*. Populations now placed in race *fraterculus* were previously listed as race *elegans*; however, type locality of *elegans* (Sadiya, in NE Assam) subsequently reckoned to fall within range of *speciosus*, making these two synonyms, and leaving *fraterculus* as the name for populations from S Assam to Hainan. Proposed race *suchitrae* (W & SW Myanmar E to C & S Indochina) considered indistinguishable from *semiruber*. Nineteen subspecies currently recognized.
Subspecies and Distribution.
P. f. speciosus (Latham, 1790) – Himalayas from Jammu and Kashmir E to S China (SE Xizang).
P. f. fraterculus Swinhoe, 1870 – NE India (hills of Assam S of R Brahmaputra), N Myanmar, S China (Yunnan, Hainan I) and N Indochina.
P. f. flammeus (J. R. Forster, 1781) – W & S India and Sri Lanka.
P. f. semiruber Whistler & Kinnear, 1933 – EC India, S Myanmar and Thailand (except C & S) E to C & S Indochina.
P. f. andamanensis Beavan, 1867 – Andaman Is.
P. f. fohkiensis Buturlin, 1910 – SE China (Guizhou E to Fujian, S to Guangxi and Guangdong).
P. f. flammifer Hume, 1875 – SE Myanmar, SW & S Thailand and N & E Peninsular Malaysia.
P. f. xanthogaster (Raffles, 1822) – W & S Peninsular Malaysia and Sumatra (including E coast islands).
P. f. minythomelas Oberholser, 1912 – Simeulue I, off NW Sumatra.
P. f. modiglianii Salvadori, 1892 – Enggano I, off SW Sumatra.
P. f. insulanus Deignan, 1946 – Borneo.
P. f. siebersi Rensch, 1928 – Java and Bali.
P. f. exul Wallace, 1864 – Lombok (E of Bali).
P. f. novus McGregor, 1904 – N & C Philippines (Luzon, Negros).
P. f. leytensis Steere, 1890 – EC Philippines (Samar, Leyte, Bohol).
P. f. gonzalesi Ripley & Rabor, 1961 – S Philippines (N & E Mindanao).
P. f. nigroluteus Parkes, 1981 – SC Mindanao.
P. f. johnstoniae Ogilvie-Grant, 1905 – Mt Apo, in SE Mindanao.
P. f. marchesae Guillemard, 1885 – Sulu Archipelago (Jolo).

Descriptive notes. 17–22 cm; 19–24·5 g. A robust minivet with heavy bill, relatively broad tail. Male nominate race has head, chin, throat and mantle to upper back glossy blue-black, lower back, rump and uppertail-coverts fiery orange-red; upperwing black, greater coverts broadly tipped orange-red, remiges with broad band of orange-red near base, three innermost secondaries/tertials with red spot or line near tip of outer webs; rectrices black, all except central pair with orange-red tip, red increasing in extent on outers; underparts bright orange-red, thighs blackish, underwing-coverts bright yellow; iris dark brown; bill and legs black. Distinguished from all congeners by isolated red markings near tips of tertials and inner secondaries. Female has forehead and broad supraloral line bright yellow, crown to back and upperwing-coverts ashy grey to olive-washed grey, lower back, rump and uppertail-coverts greenish-yellow, remiges and rectrices blackish, red areas of male replaced by yellow; entirely bright yellow below. Juvenile is like female, but has yellowish scaly markings from crown to mantle, greyish scaling on breast side and flanks, with upperwing-coverts and tertials broadly edged yellow, suggestion of adult pattern on tertials/inner secondaries; immature as adult female, but young male has yellow areas of latter more orange. Races vary mainly in size, shade of red on male underparts, shade of yellow on female underparts, extent of bright colour on central rectrices and wings: *speciosus* is largest, male deep scarlet, less orange than nominate, with more red in wing, often some scarlet on central rectrices, female with yellow areas somewhat deeper yellow; *semiruber* differs from previous in smaller size, male outer webs of central rectrices usually red; *fraterculus* is intermediate between previous two, male central rectrices with little or no red on outer webs (variable); *fohkiensis* female has lower back to tail-coverts bright olive-green (sometimes slight golden tinge), relatively pale and greenish-tinged lemon below; *xanthogaster* is small, male with red outer webs of central rectrices, larger tertial spots, female crown to upper back slate-coloured with faint blue gloss; *flammifer* resembles previous but slightly larger, tendency for more red in male wing, female with distinct golden suffusion on lower back to tail-coverts, more yellow in wing, rather orange-tinged underparts; *andamanensis* differs from nominate in having red areas bright scarlet (rather than orange), slightly more red in wing, female with yellow areas deeper in colour; *minythomelas* is very like last, but male has much scarlet on central rectrices (almost entire outer web, tip of inner web), female has crown to upper back glossy bluish-slate (not ashy grey); *modiglianii* is also very similar, but male usually with less red in central rectrices, female slightly paler and less glossed above and with yellow areas less bright; *insulanus* male is identical to *xanthogaster*, female differs from latter in having less yellow on forehead, darker crown to upper back, bright olive-green lower back to tail-coverts (no golden suffusion), paler underparts; *siebersi* is smaller than nominate, male less intensely orange, thighs mixed orange and grey, female with rump olive-green and on average less intensely yellow below; *exul* differs from previous in male having lower back to tail-coverts bright orange-chrome (not fiery scarlet), wing and tail markings less reddish, female perhaps on average slightly paler below; *leytensis* has red areas bright orange-red, including tips of central rectrices, dark grey thighs, female has bluish-slate crown to upper back, contrasting yellow forehead and short supercilium, blackish lores, deep golden-yellow lower back to tail-coverts, bright lemon-chrome below; *novus* is like previous, but male wing markings less intensely orange, thighs mixed orange and grey, underparts brighter orange, female crown to upper back slaty black; *johnstoniae* male has lower back to tail-coverts and wing markings bright yellow-orange, central rectrices narrowly tipped same colour, underparts bright cadmium-yellow, thighs slate, female crown to upper back bluish-slate, lower back to tail-coverts deep yellow; *gonzalesi* male differs from previous in having bright areas more richly orange-yellow; *marchesae* male has bright parts of plumage bright golden yellow (not orangey); *nigroluteus* is similar to last, perhaps slightly more orangey. Voice. Loud, piercing whistles, "sweep-sweep-sweep-sweep", "weep-weep-weep-wit-wip" and similar.

Habitat. Broadleaf evergreen, semi-evergreen and deciduous forests, and peatswamp-forest; occurs also in orchards. In disturbed forest requires good cover of tall trees, and avoids low regrowth. Hills and mountains to 2100 m; below 915 m in Peninsular Malaysia.
Food and Feeding. Eats mainly insects, including caterpillars (Lepidoptera), grasshoppers and green crickets (Orthoptera) and cicadas (Cicadidae); also spiders (Arachnida). Gregarious; regularly joins mixed-species foraging flocks. Forages in canopy or in crowns of emergent trees; visits crops of ripe figs (*Ficus*), apparently for insects attracted by the fruit. Prey taken mainly in canopy foliage; also sallies after flushed prey, and hovers in front of flowers.
Breeding. Breeds in Apr–Jun in Himalayas and Feb and Jun–Oct in peninsular India; Feb–May and (second brood) Aug–Sept in Sri Lanka; Jun-Jul in SE Asia, and Mar–Apr in Lombok and Philippines. Nest a small, neat open cup of lichens, bound with cobwebs and decorated with bark, placed 6–20 m above ground on horizontal fork or tree branch. Eggs 2–3; incubation performed by female only, young fed by both sexes; no information available on incubation and fledging periods.
Movements. Mostly resident. Some altitudinal movements; in Himalayan region, descends from breeding areas (up to 1800 m or higher) to lower elevations and plains in winter; race *fraterculus* reaches NE Thailand in non-breeding season.

Status and Conservation. Not globally threatened. Widespread and common in Nepal; locally common in India, Bangladesh and China; common in Bhutan and Sri Lanka; common in SE Asia (except C Thailand) and in Philippines; scarce in Singapore. Thought to be uncommon in Borneo (race *insulanus*). Status of Lombok race *exul* unclear; apparently no recent records. Occurs in many protected areas in much of its range, e.g. Royal Chitwan National Park, in Nepal, Mudumalai National Park, in India, Kaeng Krachan National Park, in Thailand, Nam Bai Cat Tien National Park, in Vietnam, Taman Negara National Park, in Peninsular Malaysia, Way Kambas National Park, in Sumatra, and Danum Valley Conservation Area, in Borneo.

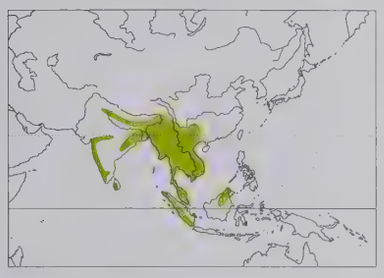
PLATE 13

inches 3

cm 8



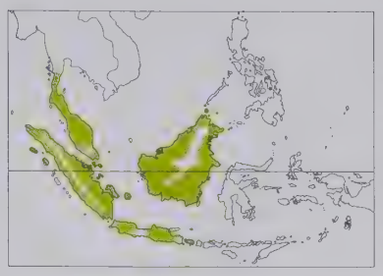
Genus *HEMIPUS* Hodgson, 1845

83. **Bar-winged Flycatcher-shrike**

Hemipus picatus

French: Échenilleur gobemouche **Spanish**: Oruguero Alibarrado
German: Elsterraupenschmätzer
Other common names: Pied Flycatcher-shrike, Pygmy Triller/Cuckoo-shrike

Taxonomy. *Muscicapa picata* Sykes, 1832, The Deccan, India.
Four subspecies recognized.
Subspecies and Distribution.
H. p. capitalis (Horsfield, 1840) – Himalayas (E from N India), S China (SE Xizang, W & S Yunnan, S & C Guizhou, W Guangxi), N, C & E Myanmar, NW Thailand, N Laos and N Vietnam (W Tonkin).
H. p. picatus (Sykes, 1832) – W, C & E India, Bangladesh, W & S Myanmar, W & E Thailand and C & S Indochina.
H. p. leggei Whistler, 1939 – Sri Lanka.
H. p. intermedius Salvadori, 1879 – S Thailand, Peninsular Malaysia, Sumatra and NE Borneo.



Descriptive notes. 14–15 cm; 8·5–9·5 g. Male nominate race has top of head, upperparts and wings glossy black, lores to ear-coverts also black, cheeks and side of neck white; rump white, upper rump barred black, uppertail-coverts black; median and greater upperwing-coverts broadly tipped white, three inner secondaries edged white (longitudinal bar on closed wing); tail black, tipped white (except central feathers), outermost feather also narrowly edged white; chin and stripe around throat side pure white; underparts greyish-white, more vinous on breast, whiter on belly, undertail-coverts and underwing-coverts; thighs ashy brown; iris red-brown; bill black; legs dark grey to black. Readily distinguished from *H. hirundinaceus* by white on wings and tip of tail. Female is like male, but glossy black areas replaced by sooty black. Juvenile resembles female, but white band on rump narrow, uppertail-coverts tipped white, rest of upperparts and lesser wing-coverts sooty brown with buff feather fringes, median and secondary coverts buff-white with two narrow brown bars, secondaries and tertials tipped and edged buff-white, underparts entirely off-white; immature apparently like female. Race *intermedius* is darker than nominate; *capitalis* has black cap and dark brown mantle; *leggei* is black above in both sexes, slightly paler below. Voice. Sharp "chisik" or "chir-rup" and shorter "tsik"; also high-pitched, trilling, repeated "wiraka".
Habitat. High, open canopy and edges of lowland forest, including disturbed forest; also secondary forest, bamboo stands, scrub, plantations and wooded gardens, including those far from true forest. In mountains, to 2100 m; breeds mainly at 600–1800 m in Himalayan region.
Food and Feeding. Takes insects, including butterflies (Lepidoptera), beetles (Coleoptera), winged ants (Formicidae) and winged termites (Isoptera). Regularly joins mixed-species flocks in canopy. Forages in manner of a flycatcher (Muscicapidae), perches upright and sallies from habitually used exposed perches; also gleans from foliage. Occasionally takes prey from ground.
Breeding. Breeds Feb–Aug in Indian Subcontinent, Apr in Myanmar, Feb and Apr in Peninsular Malaysia and Mar–Jul in China. Nest built by both sexes, a small, shallow cup of roots, fine twigs, moss and grasses, bound with cobwebs, anchored to branch 3–12 m above ground. Eggs 2–3; both sexes incubate and both care for young; no information on incubation and fledging periods.
Movements. Chiefly resident. Some altitudinal and local movements in Himalayas and NE India, with post-breeding descent to foothills and adjacent plains.
Status and Conservation. Not globally threatened. Fairly common in Indian Subcontinent, common in Nepal, Bhutan and Sri Lanka; common in SE Asia and China, but occurs rather sparingly in Myanmar. Common in N and in upland forest in Malay Peninsula, uncommon in S Malaysian lowlands; observed densities imply that major slope populations would be viable in isolation. Less numerous than *H. hirundinaceus* in Sumatra and Borneo. Occurs in several protected areas, e.g. Royal Chitwan National Park, in Nepal, Corbett National Park, in India, Kaeng Krachan National Park, in Thailand, and Taman Negara National Park, in Peninsular Malaysia.
Bibliography. Ali (1969), Ali & Ripley (1996), Ali *et al.* (1996), Deignan (1945, 1963), Duckworth *et al.* (2002), Eames & Ericson (1996), Eames & Robson (1992), Étchécopar & Hüe (1983), Grimmett *et al.* (1998), Hall (1956), Hawa (1985), Inskipp & Inskipp (1991), Jeyarajasingam & Pearson (1999), Jones *et al.* (1998), Kotagama (1985a, 1985b), Lekagul & Round (1991), MacKinnon & Phillipps (1993, 2000), van Marle & Voous (1988), McClure (1998), Medway & Wells (1976), Phillips (1940), Rasmussen & Anderton (2005), Ripley (1982), Robson (2000), Smythies (1986, 1999), Stepanyan (1995), Wells (2005).

84. **Black-winged Flycatcher-shrike**

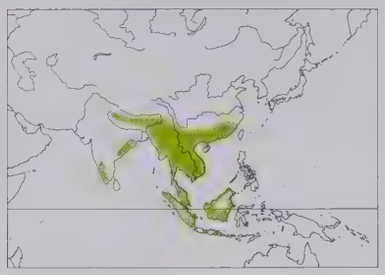
Hemipus hirundinaceus

French: Échenilleur véloce **Spanish**: Oruguero Golondrina
German: Schwarzflügel-Raupenschmätzer
Other common names: Black-winged Pygmy triller

Taxonomy. *Muscicapa hirundinacea* Temminck, 1822, Java.
Monotypic.
Distribution. Extreme S Myanmar (S Tenasserim), extreme S Thailand, Peninsular Malaysia, Sumatra (including Nias I and Simeulue I), Riau and Lingga Archipelagos, Bangka, Belitung, Borneo (including Banggi I), Java and Bali.

Descriptive notes. 14–15 cm; 10–14 g. Male has top of head, upperparts and wings black, glossed green, lores to ear-coverts also black, cheeks and side of neck white; rump white, upper rump barred black, uppertail-coverts black; tail black, outermost feather narrowly edged white; throat and underparts white, greyer from lower throat and breast to anterior flanks; underwing-coverts mottled grey and white; iris dark brown; bill and legs black. Readily distinguished from *H. picatus* by lack of white on wings and tip of tail. Female is like male, but with black areas replaced by sooty brownish. Juvenile is like female, but with buff feather fringes on upperparts, upperwing-coverts broadly fringed buff (but primary coverts tipped pale buff), tertials and secondaries tipped buff, outermost tail feather edged and tipped whitish; immature as female, but primary coverts narrowly tipped off-white. Voice. Coarse "tu-tu-tu-tu-hee-tee-tee-teet" and "hee-too-weet", interspersed with high-pitched "cheet-weet-weet-weet" and similar.
Habitat. Canopy of forest, including freshwater swamp-forest, tall secondary growth and forest edge; also mangroves, mature plantations (including old rubber plantations) and wooded gardens. Occurrence in undisturbed primary forest in Sumatra uncertain. Lowlands to 1100 m, but to 1500 m in Java and Bali; generally scarce in Malay Peninsula above 300 m, above which altitude *H. picatus* becomes common.
Food and Feeding. Eats small insects. Commonly joins canopy-level mixed-species foraging parties. Snatches insects from underside of terminal foliage while hovering; also makes short flycatching flights, usually from an exposed perch.
Breeding. Breeds in Apr–Jun in Peninsular Malaysia, Jan–Apr and Aug–Nov in Sumatra, and Aug–Sept in Borneo. Nest built by both sexes, a cup or a truncated cone with cup-shaped depression, made of lichens, bark fragments, fibres, bryophytes and spider webs, placed 7–40 m above ground on horizontal tree branch. Eggs 2; chicks fed and brooded by both parents; no information on incubation and fledging periods.
Movements. None recorded.
Status and Conservation. Not globally threatened. Scarce to locally common; in 1990s regarded as local and uncommon in Thailand and fairly common in Sumatra, Borneo, Java and Bali. Considered "Near-threatened" in Peninsular Malaysia because of its lesser presence on major slopes and its generally narrower habitat range than that of *H. picatus*; important back-mangrove forest habitat has mostly been cleared in Peninsular Malaysia. Occurs in Taman Negara National Park, in Peninsular Malaysia, Way Kambas National Park, in Sumatra, Gunung Gede-Pangrango National Park, in Java and Bali, and Danum Valley Conservation Area, in Borneo.
Bibliography. Andrew (1985), van Balen (1999), Duckworth & Kelsh (1998), Ford & Davison (1995), Hawa (1985), Hellebrekers & Hoogerwerf (1967), Holmes (1994), Holmes & Nash (1989), Jeyarajasingam & Pearson (1999), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Phillipps (1993), van Marle & Voous (1988), McClure (1998), Medway & Wells (1976), Robson (2000), Round (1988, 2000a), Smythies (1986, 1999), Strange (2002), Verheugt *et al.* (1993), Vowles & Vowles (1997), Wells (2005).

Genus *TEPHRODORNIS* Swainson, 1832



85. **Large Wood-shrike**

Tephrodornis virgatus

French: Téphrodorne bridé **German**: Großer Raupenwürger **Spanish**: Ceniciento Grande
Other common names: Brown-tailed/Hook-billed Wood-shrike/Greybird

Taxonomy. *Lanius virgatus* Temminck, 1824, Java.
Taxonomic position of genus uncertain; data derived from DNA–DNA hybridization indicate that it is closer to Prionopidae and should perhaps be placed in that family, but such treatment considered premature without further research and corroborative evidence. Species sometimes referred to by older specific name of *gularis*, but that name invalid, as preoccupied. Race *sylvicola* sometimes elevated to species rank on basis of differences in plumage and voice, and has been suggested that, for same reasons, *pelvicus* should also be treated as a separate species; review of whole complex required. Eleven subspecies recognized.
Subspecies and Distribution.
T. v. sylvicola Jerdon, 1839 – Western Ghats of India.
T. v. pelvicus (Hodgson, 1837) – E Himalayas from N India E to N, NE & SW Myanmar, also E India (Eastern Ghats).
T. v. jugans Deignan, 1948 – E Myanmar, S China (SW Yunnan) and NW Thailand (S to N Tak).
T. v. latouchei Kinnear, 1925 – S & SE China (W & SE Yunnan, Guizhov, Guangxi, N Guangdong, C & E Fujian).
T. v. hainanus Ogilvie-Grant, 1910 – N Laos, N Vietnam and Hainan I.
T. v. vernayi Kinnear, 1924 – SE Myanmar (S to N Tenasserim) and SW Thailand.
T. v. annectens Robinson & Kloss, 1918 – S Myanmar (S Tenasserim) and S Thailand.
T. v. mekongensis Meyer de Schauensee, 1946 – E & SE Thailand, S Laos, Cambodia and S Vietnam.
T. v. fretensis Robinson & Kloss, 1920 – SE peninsular Thailand, Peninsular Malaysia (S from Perlis and Narathiwat) and N Sumatra.
T. v. virgatus (Temminck, 1824) – S & SW Sumatra and Java.
T. v. frenatus Büttikofer, 1887 – Borneo.
Descriptive notes. 18·5–23 cm; 28–46 g. Thickset bird with heavy bill, distinct nasal tufts. Male nominate race has white forehead, blue-black mask from lores around eye to ear-coverts; otherwise, blue-grey above, with white lower rump; primary coverts and remiges blackish, edged blue-grey, secondaries and tertials mostly blue-grey; uppertail-coverts and tail black; cheeks, neck side, throat and underparts white, slightly washed greyish-pink on breast; axillaries and underwing-coverts blue-grey; iris yellow-brown to yellow; bill black; legs grey-black. Distinguished from *T. pondicerianus* by larger size, no white supercilium, more white on rump, no white in tail. Female is duller than male, with paler upperwing-coverts, hardly any white on forehead, paler and browner mask, outer rectrices edged and tipped white, eye sometimes pale blue, bill horn-brown. Juvenile has browner upperparts than female, with whitish shafts and feather tips from crown to mantle and scapulars, buffish and

On following page: 86. Common Wood-shrike (*Tephrodornis pondicerianus*).

whitish bars on upperwing-coverts and tertials, rectrices fringed dark buff; immature like female, but not fully described. Races differ mainly in size, and in colour of male upperparts and underparts: *sylvicola* has dark grey-brown upperparts, browner remiges; *pelvicus* has pale brown upperparts and tail, brownish breast, sometimes slight white stripe below mask; *annectens* has upperparts more greyish-washed, less contrasting; *vernayi* is intermediate between previous two, larger than latter, upperparts ashy brown (not ashy grey); *jugans* has grey crown and nape, grey-brown upperparts, no white on forehead; *fretensis* is smaller, pale dove-grey from crown to anterior mantle, then darker grey to back; *latouchei* has very brown mantle to rump, rufous edges of inner remiges and greater coverts; *hainanus* is dull, with grey crown and brown upperparts, female even browner; *frenatus* has less white on forehead, white on uppertail-coverts, browner wings and tail, vinaceous-grey underparts with contrasting white cheeks. Voice. Song a loud, ringing "pi-pi-pi-pi-pi-pi" or "ki-ki-ki-ki" and so on, or repeated "kee-a"; call a harsh, scolding, repeated "chreek". Song of race *sylvicola* a loud, ringing "ker-wíck-er-wíck" or "wíckywíckywícky-wíck-er-wíck"; calls of *sylvicola* and *pelvicus* include low-pitched "gwup" and harsh, reedy rasps.

Habitat. Broadleaf evergreen forest, mixed deciduous forest, forest edge, logged forest with some tall trees, secondary growth and woodland; sometimes overgrown plantations, wooded gardens and mangroves. Mainly in secondary forest in Sumatra; in China favours forest edges and clearings. Lowlands and hills, to 1500 m.

Food and Feeding. Eats large insects, especially mantids (Mantidae), crickets (Gryllidae), stick-insects (Phasmatodea), grasshoppers and locusts (Acrididae), beetles (Coleoptera), dragonflies (Odonata), large moths (Lepidoptera) and caterpillars (including hairy ones), also "grubs"; some fruit also taken (berries recorded). Usually occurs in pairs or small groups; often associates with mixed-species foraging flocks. Forages in tree crowns, also in understorey, often moving rather sluggishly; descends to the ground only very occasionally. Gleans from leaves and branches, making short sallies after disturbed insects; often sallies from a perch; pries into bark fissures on trunks and branches; also takes insects from water surfaces.

Breeding. Breeds Dec–Jun (mainly Mar–May) in India and in Mar–May in SE Asia. Nest a shallow saucer of interwoven fine grass stems, roots, twigs and tendrils, incorporating lichens and bound with cobwebs, placed on horizontal tree branch 3–9 m above ground. Eggs 2–4; no information on incubation and fledging periods.

Movements. Resident. Some local and altitudinal movements in Himalayas and Peninsular India; in N Thailand, thought to move in cold weather from open evergreen forest at 600–1400 m to dry deciduous forest at lower elevations in plains and foothills. Suspected that pioneer invaders of non-forest habitats in Peninsular Malaysia are nomadic.

Status and Conservation. Not globally threatened. Fairly common to locally common in Nepal and India; common throughout its range in SE Asia, but extinct on Singapore. Frequent in forests of Sumatra and Borneo in 1990s, but uncommon in Java. Race *latouchei* uncommon in S China; current status on Hainan (*hainanus*) unclear, but was uncommon in 1980s. Race *fretensis* regarded as "Near-threatened" in Malay Peninsula as a result of habitat loss; although it can occupy man-made habitats such as overgrown plantations, these are at a premium as agriculture intensifies. Probably has some resistance to impact of logging.

Bibliography. Ali (1969, 1986), Ali & Ripley (1996), Ali *et al.* (1996), van Balen (1999), Cheng Tsohsin (1987), Deignan (1945, 1963), Dickinson, E.C. (2003), Dickinson, E.C. & Dekker (2002a), Eames & Robson (1992), Étchécopar & Hüe (1983), Harrison & Parker (1965), Hawa (1985), Hellebrekers & Hoogerwerf (1967), Inskipp & Inskipp (1991), Jeyarajasingam & Pearson (1999), Lekagul & Round (1991), MacKinnon & Phillipps (1993, 2000), van Marle & Voous (1988), McClure (1998), Medway & Wells (1976), Rasmussen & Anderton (2005), Ripley (1982), Robson (2000), Round (1988), Smythies (1986, 1999), Stepanyan (1995), Vijayan (1989), (1992), Wells (2005).

86. Common Wood-shrike

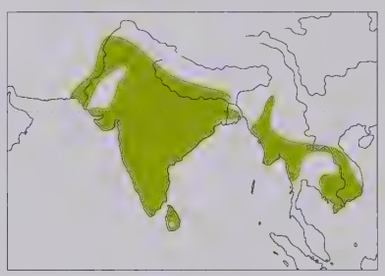
Tephrodornis pondicerianus

French: Téphrodorne de Pondichéry **Spanish**: Ceniciento Chico
German: Kleiner Raupenwürger

Other common names: Lesser Wood-shrike; Ceylon Wood-shrike (*affinis*)

Taxonomy. [*Muscicapa*] *pondiceriana* J. F. Gmelin, 1789, Coromandel Coast = Pondicherry, south-east India.

Taxonomic position of genus uncertain; data derived from DNA–DNA hybridization indicate that it is closer to Prionopidae and should perhaps be placed in that family, but such treatment considered premature without further research and corroborative evidence. Race *affinis* sometimes regarded as a separate species. Nominate race intergrades with *pallidus* in NW India. Four subspecies recognized.



Subspecies and Distribution.

T. p. pallidus Ticehurst, 1920 – Pakistan (E Baluchistan, Punjab, Sind) and NW India (from foothills S to Gujarat and NC Uttar Pradesh).

T. p. pondicerianus (J. F. Gmelin, 1789) – India (except NW) and S Nepal and Bangladesh E to Myanmar, Thailand (except S) and C & S Laos.

T. p. affinis Blyth, 1847 – Sri Lanka.

T. p. orientis Deignan, 1948 – Cambodia and S Vietnam.

Descriptive notes. 14·5–18 cm; 18–27 g. Male nominate race is brownish-grey above, including upperwing, with pronounced whitish supercilium, grey-brown lores, blackish-brown mask from around eye to ear-coverts; rump feathers with small white tips (variable), uppertail-coverts black; rectrices blackish-brown, outer two pairs white with terminal blackish spot; cheeks and chin white; white throat and underparts, more pale ashy on breast (tinged pink in fresh plumage); axillaries and underwing-coverts ashy grey; iris dull yellow; bill dusky brown; legs dusky grey. Differs from *T. virgatus* mainly in smaller size, smaller bill, presence of white supercilium and white outer tail. Female is like male, but mask slightly paler. Juvenile has upperparts browner and spotted whitish-buff, particularly on crown and nape, upperwing-coverts broadly tipped whitish-buff, pale and dark markings on tertials, side of throat and breast mottled dusky brown; immature like adult, but not fully described. Race *pallidus* is paler than nominate, more ashy grey above and creamy below; *affinis* has shorter tail, much less obvious supercilium, and is darker, slate-grey, above, with more white on rump, wings ashy brown, remiges washed grey on outer edges, female duller, browner above, washed ashy brown below, supercilium more distinct; *orientis* is darker, dark brown-grey above, with white rumpband, strong white supercilium, darker malar area, strong brownish tinge below. Voice. Song an accelerating trill, "pi-pi-i-i-i-i-i-i"; contact calls include weak "tue" and "tee" notes, and harsher "wih-wih-whee-whee". Race *affinis* has a sweet, loud song, "fit-fwít-fwít-fwít-fwéét-fwéét" and a "chyup" call.

Habitat. Open forest, dry deciduous forest, secondary growth, bamboo forest, woodland, scrub, orchards, gardens, hedgerows, and dry open country with scattered trees. Lowlands, ascending locally to 1500 m.

Food and Feeding. Takes insects, chiefly beetles (Coleoptera), adult and larval lepidopterans, and orthopterans; also spiders (Arachnida), and some fruit. Occurs in pairs and small groups; frequently joins mixed-species foraging parties. Forages in treetops, searching diligently in bark crevices and beneath leaves; also sallies for flying insects, and sometimes takes prey on the ground.

Breeding. Season Feb–Jul. Nest built by both sexes, a small, neat, shallow cup of moss, lichen, bark or roots, bound with cobweb, lined with hair or vegetable down, placed in horizontal fork of tree branch 2–9 m above ground. Eggs 2–4; both parents incubate eggs and both feed nestlings; no information on incubation and fledging periods.

Movements. Resident; possibly some seasonal wandering.

Status and Conservation. Not globally threatened. Fairly common to common throughout its range.Widespread and common in most of Indian Subcontinent; locally fairly common in Nepal. Common in SE Asia.

Class AVES

Order PASSERIFORMES

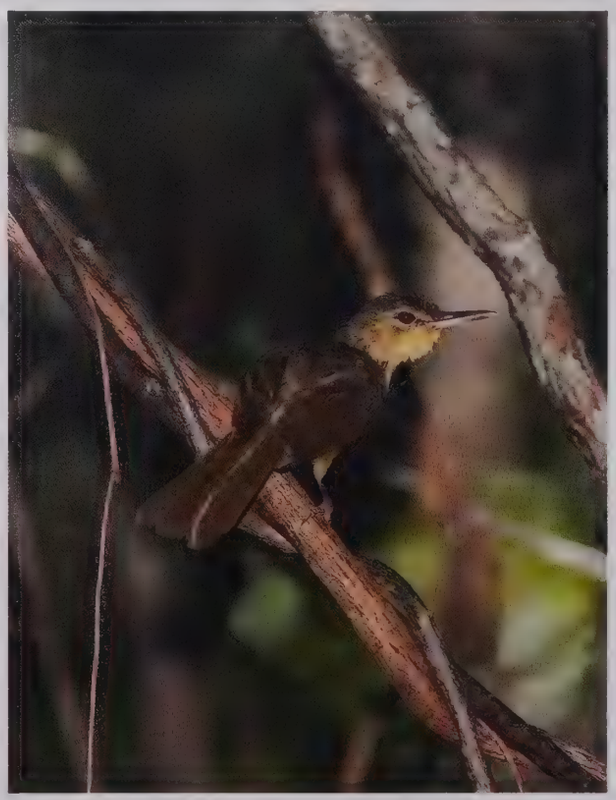
Suborder OSCINES

Family PYCNONOTIDAE (BULBULS)

- Medium-sized, slender-bodied, short-necked passerines with rounded wings, longish tail, relatively small legs, and medium-length bill, often with prominent rictal bristles; plumage generally sombre, many with crest.
- 13–29 cm.

- Africa and southern Asia.
- Forest, woodland, scrub and thickets.
- 27 genera, 138 species, 355 taxa.
- 13 species threatened; none extinct since 1600.

Systematics



The family Pycnonotidae is a large and varied group of ten-primaried oscine passerines, widespread in Africa and southern Asia, but absent from Europe. It has reached most islands of eastern Indonesia, thus crossing Wallace's Line, but it never successfully colonised New Guinea. Its species occupy a broad range of habitats from semi-deserts to lush rainforests, with centres of diversity in the Afrotropical and Sundaic regions.

J. Delacour, in his 1943 revision of the family, considered it to constitute one of the most clearly defined groups of the oscine passerines. In other words, he felt that "the different genera and subgenera which belong to the group are obviously related to one another and rather far removed from any others", although he was careful to note that a few other genera, which may be fairly closely related to them, were difficult to classify taxonomically according to the state of knowledge existing at that time.

Over sixty years later, Delacour's view of the Pycnonotidae still largely holds good. In revising the family, he gave reasons for omitting a number of other groups assigned to it by earlier authors. These include the leafbirds (Chloropseidae), the fairy-bluebirds (Irenidae) and the ioras (Aegithinidae), and this view has been followed for the most part by subsequent authors, although there has been a recent suggestion, based on osteological evidence, that the Chloropseidae are nectarivorous bulbuls. The bulbuls have traditionally been allied with the cuckoo-shrikes (Campephagidae), with which they share dense and abundant feathering of the rump, but this association is not supported by subsequent studies, first of egg-white proteins and, more recently, of DNA. While these analyses are not consistent with one another in their findings, two of the more recent ones do, nevertheless, indicate a close relationship with the grass-warbler genus *Cisticola* and its allies the prinias (*Prinia*), the apalises (*Apalis*) and several other genera, all of which are often united in their own family (Cisticolidae). If confirmed by further research, this alliance of two groups notorious for their monotonous uniformity of plumage will doubtless strike many as fitting.

Since Delacour's revision was published, there has, however, been a considerable amount of agonizing over a number of those "other genera" which he found difficult to classify, as well as over some other subsequently suggested contenders. More recently, the position of several of these has been resolved through morphological, ecological and, especially, molecular studies, at least so far as excluding them from the Pycnonotidae is concerned, but some remain problematic. Without attempting an exhaustive review, it is worth giving a brief outline of some of the more persistent, recently resolved or unresolved cases involving taxa which are now considered not to belong with this family.

Thus, the position of the Kinkimavo (*Tylas eduardi*) of Madagascar remains uncertain. Although Delacour, A. L. Rand and H. G. Deignan and others treated this species as a bulbul, they all did so with reluctance and, more recently, the weight of opinion has been to consider it an aberrant member of the vanga family (Vangidae); indeed, it is often referred to as the Tylas Vanga, or simply the Tylas. Subsequent osteological studies have corroborated the view that it does not belong in the Pycnono-

Five Madagascan species have long been grouped with African Phyllastrephus *bulbuls. Superficially bulbul-like, they differ in voice and behaviour, and the results of genetic analyses suggest they should be removed from the family altogether. On the basis of these revelations, four are placed in* Xanthomixis, *and a fifth, the inordinately long-billed* ***Common Tetraka****, is placed in* Bernieria. *All five probably belong to a separate Malagasy radiation of passerines, as yet unnamed, but they are retained within the Pycnonotidae until the implications of this recent discovery are more perfectly understood.*

[*Bernieria madagascariensis inceleber*, Ampijoroa, Madagascar. Photo: Joe Tobias]

The bulbul sequence begins with the finchbills, a pair of allospecies typical of the family in most respects, except their stubby bills. This unusual feature possibly relates to a diet of sturdy seeds or fruit, but no such adaptive significance has been identified. Both species are social, especially in the non-breeding season, and have a year-round preference for scrub-covered slopes, clearings and broken forest. They are found in Asiatic mountains, those in south China and northernmost Vietnam being occupied by the ***Collared Finchbill****.*

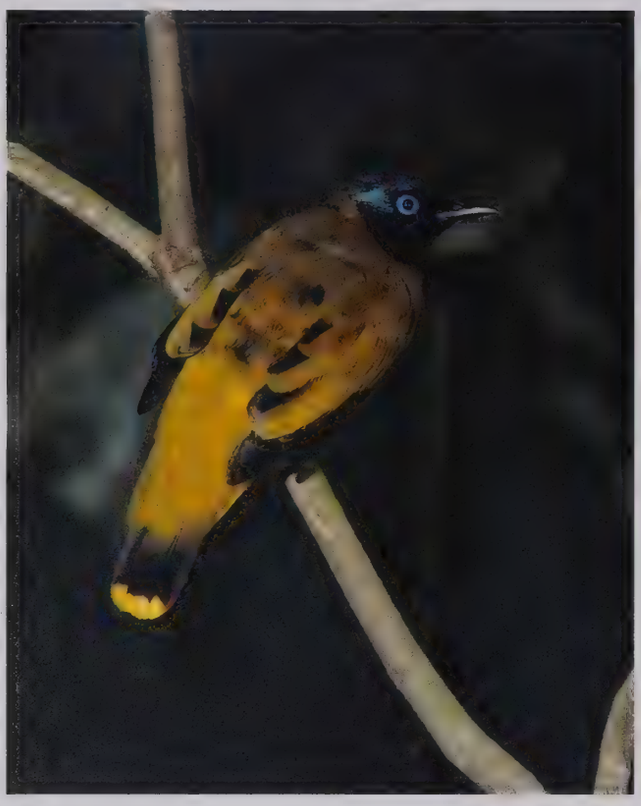
[*Spizixos semitorques semitorques*, Wolong Nature Reserve, Sichuan, China. Photo: Bernard van Elegem]

tidae, although its affinity with the vangas is also tenuous. An enigma it remains.

The Malia (*Malia grata*), a denizen of mountain forests of Sulawesi, was provisionally placed with the Pycnonotidae by C. M. N. White and M. D. Bruce on account of similarities of its plumage and coloration to those of the bulbuls, and also through deduction, "because the absence of a bulbul on Sulawesi is strange". Delacour mentioned that its large feet looked like those of a bulbul that had grown bigger because of a terrestrial lifestyle. It transpires, however, that the Malia is an arboreal bird, with feet very similar to those of laughingthrushes (*Garrulax*), another group lacking a representative on Sulawesi. Its calls, and the comportment and locomotion of groups of individuals as they move through the middle stratum of the forest, are certainly reminiscent more of *Garrulax* than of any bulbul. Furthermore, the Malia differs osteologically from the bulbuls in a number of respects, including the absence of any of the nasal ossification characteristic of pycnonotids (see Morphological Aspects). For these reasons, it is considered to be better placed with the babblers (Timaliidae).

Kretschmer's Longbill (*Macrosphenus kretschmeri*) of the coastal forests of East Africa is another oddity that has in the past been considered a bulbul. It was previously treated in a monotypic genus, *Suaheliornis*, but is now placed, apparently non-controversially, with the longbills in the genus *Macrosphenus*, and is regarded as a sylviid warbler. A more recent East African departure from the family has been the Dappled Mountain-robin (*Modulatrix orostruthus*), which was originally described as a bulbul in the genus *Phyllastrephus*. It has since been established, on the basis of its structure, proportions and coloration, that this species it is not a pycnonotid, but whether it is a thrush (Turdidae), a timaliid or something else is still a matter of contention.

One possible recruit to the Pycnonotidae is the Blackcap Mountain-babbler (*Lioptilus nigricapillus*), sometimes called the "Bush Blackcap", of South Africa, which is currently placed in the Timaliidae. In several aspects of its behaviour, ecology, voice and proportions it appears to have more in common with the bulbuls than with the babblers, but, because there is no new evidence to justify its transfer, it is better left with the Timaliidae pending DNA studies.



With these exclusions taken into account, the family Pycnonotidae comprises a total of 138 species. Recent DNA analysis and other studies, however, suggest that eight of these, in three genera, are probably not pycnonotids. These are the three nicators (*Nicator*), the Common Tetraka (*Bernieria madagascariensis*) and the four tetrakas in the genus *Xanthomixis*, the correct position of all of which has also long been a matter of uncertainty. Nevertheless, as these findings are sufficiently recent that their implications are not yet fully understood, the eight species in question are retained in Pycnonotidae as a matter of convenience, and are discussed further at the end of this section.

Even when taking into consideration only those undisputed members of the family, the systematic history of the Pycnonotidae has shown plenty of taxonomic uncertainty, concerning both generic attribution and species limits. One difficulty is that, although groups are highly variable, they are often not neatly separable, such that Deignan, in 1942, stated of his expanded genus *Hypsipetes*: "I have been quite unable to discover char-

With 42 species, and a span from South Africa to Japan, Pycnonotus *is the most diverse and widespread genus in the family. It seems clear, however, that its content is polyphyletic and destined to be subdivided by future reviewers. The* ***Cream-striped Bulbul****, for example, a mottle-chested bird of Sumatran forests, is currently placed by some in the subgenus* Alcurus. *An analysis of morphology, voice and genetics may well conclude that* Alcurus*, along with several other distinctive subgroups, deserves recognition as a genus, but given the complexity of relationships within* Pycnonotus *further study is required to establish firm conclusions.*

[*Pycnonotus leucogrammicus*, Mauro Sako, Sumatra. Photo: Christian Artuso]

*For many decades the **Black-headed Bulbul** generated taxonomic confusion on account of its colour morphs. The plumage of normal individuals is characterized by bright yellow tones, and grey morphs were repeatedly described as separate species. It was eventually determined that greyness was a chromatic aberration arising randomly and rarely, except on certain islands, such as Bawean in the Java Sea, where grey birds predominate.*

acters which might be used to separate any one group from those others most related."

Of the 27 genera currently treated within the family, eleven are exclusively Asian and 14 are restricted to Africa and the islands of the western Indian Ocean. The remaining two are represented in both continents. The species are almost equally divided between these two regions, with 70 in Asia and 67 in Africa and the west Indian Ocean islands. The White-eyed Bulbul (*Pycnonotus xanthopygos*) is the only member of the family that extends westwards to the eastern Mediterranean, being found from Turkey and the Middle East southwards to Sinai, in extreme north-east Egypt, and to the Arabian Peninsula. Although a number of recently proposed changes in nomenclature and taxonomy have been adopted, it is highly probable that others will become necessary when the results of future research are available, and there are likely to be significant shifts in bulbul taxonomy in years to come.

A recent phylogenetic study, using mitochondrial DNA, of a suite of Asian and African species showed strong support for the monophyly of twelve African species from six genera tested, whereas for 14 Asian species from a further six genera the evidence for monophyly was much less strong. This study, in fact, raised the possibility of separate radiations across both continents, so broad was the genetic disjunction between African and Asian bulbuls. Also of significance was the fact that the Common Bulbul (*Pycnonotus barbatus*) of Africa fell firmly within the clade formed by the four Asian *Pycnonotus* species analysed, and not with the African taxa, suggesting that the open-country *Pycnonotus* bulbuls in Africa may be relatively recent colonists.

The genus *Pycnonotus*, with 42 species, is by far the largest of the family. As currently constituted, it is almost certainly polyphyletic but, in the absence of a full revision, an essentially traditional view of the genus is deemed to be the best option. An example of taxonomic history clouded by convoluted and conflicting treatments is provided by the Asian "*Pycnonotus melanicterus* complex". Forms of this complex occur in Sri Lanka (*melanicterus*), in south India (*gularis*), in north India, Myanmar and south to Thailand and Indochina (*flaviventris*, along with a range of other forms), in Sumatra and Java (*dispar*) and in Borneo (*montis*). In the 1950s, Deignan eventually united Bornean *montis* and Sri Lankan *melanicterus* with *dispar*, bringing the process of lumping to its conclusion, which resulted in a widespread and highly variable species, the "Black-crested Bulbul" (*P. melanicterus*). He argued that all characters, such as the presence or lack of a crest, of a red throat, of white tail tips, and so on, arose independently throughout the complex. Nevertheless, while it is clear that all of these bulbul forms derive from a common ancestor, they have diverged significantly, and it now seems that elevation of most of them to full species rank is justified, especially in view of the differences in voice and behaviour that were not apparent to the museum workers who made the decision to lump all forms in the first place. When representative specimens of all these forms are laid in a row, starting with Sri Lankan skins and ending with Bornean ones, they reveal a degree of morphological variation that would be hard to sustain were they all members of a single species. Most interestingly, the first in the sequence, *melanicterus*, is very similar to the last, *montis*, but a whole range of features is found in between.

The recurrent variable is a red throat, this being standard in some populations and representing a colour morph in others. Variation in crest length, wing length and the colour of the upperparts is highly marked and seems to justify the treatment of these forms as full species, as also do differences in structure and voice. In some cases, however, the variation is clinal, blurring the issue. The most sensible solution would appear to be to treat each of the outlying distinct forms as monotypic species, respectively the Bornean Bulbul (*Pycnonotus montis*), the Black-capped Bulbul (*Pycnonotus melanicterus*), the Flame-throated Bulbul (*Pycnonotus gularis*) and the Ruby-throated Bulbul (*Pycnonotus dispar*), and to keep the South-east Asian forms intact as a polytypic species, the Black-crested Bulbul (*Pycnonotus flaviventris*), thus reverting to a position close to the classification in vogue a century ago. Much of the wide variation among the populations of the last-mentioned species is clinal, or the manifestation of colour phases. A red or orange throat is a permanent feature of the south Indian Flame-throated Bulbul and the Indonesian Ruby-throated Bulbul. It appears with variable frequency in several continental races of the Black-crested Bulbul in South-east Asia; strangely, it is very common in some localities, such as parts of the east Thailand plateau, accounting for most of the population of the subspecies *johnsoni* there, but it is almost absent in other parts of the range of the same subspecies.

Both *gularis* and *dispar* have at times been called the "Ruby-throated Bulbul". Indeed, the former was once very commonly identified by this appellation. In choosing which of the separated forms would take this English name, one must take into account the accuracy of the description. The throat of *dispar* equates much

more closely to the colour of rubies than does the throat of *gularis*, which, as Viscount Walden noted in 1866, is "a bright flame-coloured orange". Thus, *dispar* merits the name "Ruby-throated Bulbul", while *gularis* is more appropriately named the "Flame-throated Bulbul".

The entire "*P. melanicterus* complex" was previously placed in a separate genus, *Rubigula*. This was later lumped with *Pycnonotus*, as were several other earlier genera. The Straw-headed Bulbul (*Pycnonotus zeylanicus*) was formerly placed in the genus *Trachycomus*, the Striated Bulbul (*Pycnonotus striatus*) and its allies in *Alcurus*, the Red-whiskered Bulbul (*Pycnonotus jocosus*) and its allies in *Otocompsa*, the Black-headed (*Pycnonotus atriceps*) and Grey-headed Bulbuls (*Pycnonotus priocephalus*) and a few others in *Brachypodius*, the Asian Red-eyed Bulbul (*Pycnonotus brunneus*) and its allies in *Brachypus*, the Puff-backed Bulbul (*Pycnonotus eutilosus*) in *Euptilosus*, the Black-and-white Bulbul (*Pycnonotus melanoleucos*) in *Microtarsus*, and the Scaly-breasted (*Pycnonotus squamatus*) and Grey-bellied Bulbuls (*Pycnonotus cyaniventris*) in *Ixidia*. This lumping of many genera in *Pycnonotus* in the first half of the twentieth century by ornithologists such as Delacour and Deignan seems somewhat over-zealous today, and combines a miscellany of groupings which exhibit dramatically different vocal, behavioural and morphological characters. A strong case can be made for resurrecting most of these historical genera, as this would more accurately convey the diversity of forms currently dumped in an excessively heterogeneous *Pycnonotus*. Moreover, the sequence used to crowd this diversity of forms together under a single name seems to disconnect related taxa. When the puzzle is finally deciphered using an up-to-date analysis of genetics, morphology and voice, the traditional sequence will no doubt be viewed as hopelessly inaccurate. Be that as it may, it is probably better to refrain from subdividing or rearranging the genus until such a review is undertaken.

A number of races of the Common Bulbul are sometimes treated as full species. These include *tricolor*, *dodsoni* and *somaliensis*. It has been claimed that the nominate race and these three all meet in Ethiopia without interbreeding and that the nominate race and *tricolor* occur sympatrically in other parts of their ranges; equally, it has been claimed that all are linked by a series of populations exhibiting intermediate characters. Further study is clearly needed. The Common Bulbul is, however, parapatric and locally sympatric with both the African Red-eyed Bulbul (*Pycnonotus nigricans*) and the Cape Bulbul (*Pycnonotus capensis*), and it hybridizes extensively with both in narrow transition zones along at least part of the boundaries between their respective distributions. Hybrids exhibit variably intermediate characters, including a wide range of variation in size and, particularly, in the colour of the eye wattles, which may differ from those of either parent. For example, typical Common Bulbuls have a narrow black wattle, and typical African Red-eyed Bulbuls have a wattle that is wide and bright orange. In the phenotypic hybrids, the wattle may be black with some faint yellow tinges, half black, half dull yellow, completely dull yellow, dull orange or bright orange.

This may be of significance in the interesting problem posed by the Blue-wattled Bulbul (*Pycnonotus nieuwenhuisii*) of the Sundaic region of Asia. Only two old specimens of this form exist; one is from Borneo and the other from Sumatra. On the basis of these specimens, and from recent sightings in Brunei, in north Borneo, a theory has been forwarded that this bulbul represents a hybrid form. While it seems inevitable that one parent must be the Black-headed Bulbul, the identity of the other is less certain but has been postulated as being the related Grey-bellied Bulbul. This would explain the head pattern, but the conspicuous blue wattles and the unusual tail pattern would have to have been thrown up randomly. The hybrid theory seems attractive as an explanation for the lack of reports of this bulbul in Malaysia and Indonesia, despite increasing amounts of fieldwork in the region's forests, but there are a few problems with it. The light blue wattles around the eyes of the adult are a feature not exhibited by any other pycnonotid, suggesting that hybridization has produced a striking novel character. This is not impossible, but it does seem unlikely; in the African hybrid examples, all of the parent species possess wattles. Thus, while there is some evidence consistent with a hybrid origin, this is by no means proven, and for the time being the Blue-wattled Bulbul is considered best treated as a full species. It is perhaps merely difficult to find, possibly because of nomadic tendencies or some specialized habitat requirements. If it is found to be a valid taxon, it is one of the world's most poorly known and inexplicably rare species of bird (see Status and Conservation).

Undoubted instances of hybridization are known in Pakistan, where three taxa often interbreed, producing fertile hybrids. These are the Red-vented Bulbul (*Pycnonotus cafer*) of the race *intermedius*, the Himalayan Bulbul (*Pycnonotus leucogenys*) and

*The **Ruby-throated Bulbul** differs from the **Black-crested Bulbul** in a range of features, including its shorter crest, its pin-like red throat feathers and its vocalizations. The two forms are clearly related, however, and have normally been treated as conspecifics within a widespread taxon called* "Pycnonotus melanicterus". *Given the morphological, vocal and behavioural variation within this taxon, it seems appropriate to restore a narrower view of species limits, thus reverting to the complex of five allospecies familiar to early taxonomists.*

[Left: *Pycnonotus dispar*, Selat, Karangasem, Bali. Photo: Tony Tilford.

Right: *Pycnonotus flaviventris caecilii*, Fraser's Hill, Malaysia. Photo: Morten Strange]

Taking the date of first description as a measure of seniority, the three oldest species in Pycnonotus *are the Red-whiskered Bulbul* (P. jocosus)*, the Cape Bulbul* (P. capensis) *and the Red-vented Bulbul* (P. cafer)*. Indeed, these were the only bulbuls to appear in the volumes of* Systema Naturae*, published by Linnaeus around 1760. While* jocosus *forms part of the subgenus* Otocompsa*,* capensis *and* cafer *each form the crux of a species complex, the former chiefly African, the latter Asiatic, which together make up the core of classic* Pycnonotus *species. The* capensis *and* cafer *superspecies boasts several members, one of which is the* ***African Red-eyed Bulbul****. All are birds of scrubby country, wooded gardens or open forests, and their morphology is relatively constant. They are familiar, inquisitive, opportunistic birds, with strong multi-purpose bills and stout legs. In terms of patterning there is a tendency for dark plumage on the head, sometimes exaggerated by crests, or offset by contrastingly coloured eyerings. The close evolutionary relationship between these allospecies, and with their nearest allies in* Pycnonotus*, manifests itself most conspicuously in contact zones where interbreeding is frequent.*

[*Pycnonotus nigricans nigricans*, Kalahari Gemsbok National Park, South Africa. Photo: Alan Wilson/ Photo Access]

*The **Orange-spotted Bulbul** is an island form, endemic to the montane forests of Java and Sumatra, where it is locally common. Its comportment and voice are recognizably bulbul-like, but it differs from continental* Pycnonotus *species in several ways. Its bill is relatively slender, and its facial markings are unique. As with most of its congeners in the Sundaic realm, knowledge of its behaviour, ecology and true taxonomic affinity is extremely sketchy. Likewise, its membership of* Pycnonotus *is tentative, and in need of resolution via a thoroughly sampled and systematic review.*

[*Pycnonotus bimaculatus*. Photo: Brian J. Coates]

the White-eared Bulbul (*Pycnonotus leucotis*). In north Pakistan, hybrids between the last two form a swarm, sufficiently distinct that it was described as a separate subspecies, "*humii*". Although, away from this region, the two species are morphologically distinct, this hybrid swarm is enough to convince some taxonomists that the White-eared and Himalayan Bulbuls should be treated as conspecific. Less commonly, these two interbreed with the race *intermedius* of the Red-vented Bulbul, again producing fertile hybrids. This situation, and others like it, led to serious confusion among early systematists, who described several new species or subspecies from what were, in fact, hybrids. These circumstances also reveal how narrow the genetic distance between various bulbul forms is, and provide interesting case studies illustrating the process of speciation and tests of the various definitions of species limits.

Taxonomic problems were thrown up also by the different morphs of the Black-headed Bulbul. At one time or another these were described as separate species, such as "*P. cinereiventris*" from north-east India and "*P. chalcocephalus*" from Java, and it was many decades before it was determined that they were merely morphs. Back in 1878, that astute observer A. O. Hume noted that "it is a curious fact that you can manufacture *cinereiventris*, or the Sumatra *chalcocephalus*, or any intermediate form to any extent by the use of a little carbolic acid. Where the colour is pure yellow, as at the tips of the tail, the feathers come out *white*, as in these parts in *chalcocephalus*, but wherever the peculiar yellow olivaceous green prevails, there the feathers remain of the exact ash grey that we find in *cinereiventris* and *chalcocephalus*." He went on to deduce that what had happened appeared to be simply that, for some reason, the skin had in some parts, as with *cinereiventris*, or wholly, as with *chalcocephalus*, ceased to secrete the yellow pigment. This theory met with strong opposition at first, but was later proved correct. Individuals with no yellow pigment arise haphazardly throughout the population. They are usually rare but, oddly, they are common in some regions, as on the island of Bawean, north of Java.

In line with this lumping of colour variants, the form discovered and described by Hume as "*Brachypodius fuscoflavescens*" was soon treated as a washed-out race of the Black-headed Bulbul restricted to the Andaman Islands. It has recently been revealed that it exhibits constant differences from other races of this polymorphic species in a suite of plumage features, as well as in voice, and it is therefore accorded full species status as the Andaman Bulbul (*Pycnonotus fuscoflavescens*). If the genus *Pycnonotus* is broken up into constituent subgroups, as described above, this island form will once again bear the name applied to it by Hume in 1873. Several other isolated forms of *Pycnonotus* are almost certainly worthy of recognition at the species level. One obvious case is that of the Bornean subspecies *leucops* of the Flavescent Bulbul (*Pycnonotus flavescens*). This taxon, often referred to as the "Pale-faced Bulbul", must have been isolated for a very long time; it is much more divergent than are the other races of the Flavescent Bulbul, and apparently has different vocalizations. The upgrading of this and several other taxa to the rank of species is, however, better postponed until proper and full documentation is available.

In the past, the African genus *Andropadus* has often been merged with *Pycnonotus*, but the more recent preference has been to regard the two as separate. Differences in plumage, behaviour and ecology seem fully to justify this split, even before it was corroborated by the latest DNA evidence. Although twelve species are placed in *Andropadus*, this arrangement carries little conviction on two counts. One is that it is highly likely that, as currently constituted, *Andropadus* is polyphyletic, and should probably be split into two or more genera, while the second is that there is some evidence to suggest that one, and possibly more, forms presently treated as subspecies may warrant species status. A number of recent studies, particularly the molecular analyses and phylogenetic work of M. Roy and co-workers, have shed some light on the interrelationships within the genus. These have focused on the montane bulbuls of eastern Africa and the Cameroon Highlands, and have demonstrated that these pycnonotids constitute a monophyletic group that probably originated in the Pleistocene. This group is provisionally treated as comprising five species: the Stripe-cheeked Greenbul (*Andropadus milanjensis*), Shelley's Greenbul (*Andropadus masukuensis*), the Cameroon Montane Greenbul (*Andropadus montanus*), the Western Mountain Greenbul (*Andropadus tephrolaemus*) and the Eastern Mountain Greenbul (*Andropadus nigriceps*). In earlier years, the East African *masukuensis* was often treated as synonymous with the West African *montanus*, but plumage and vocal

The results of an analysis of evolutionary relationships within the genus Pycnonotus *might reveal that the **Stripe-throated Bulbul** groups together with Sundaic taxa, rather than with its congeners in south Asia and Africa, and also that two species are involved. The crown, ear-coverts and throat of the most familiar races,* eous *and* finlaysoni, *are streaked with yellow, but this feature is greatly subdued in the poorly known form* davisoni. *Given the presumed importance of facial patterning in courtship behaviour,* davisoni *might warrant treatment as a separate species. The best place to investigate this notion is the lower Sittang River, in Myanmar, as here the ranges of* finlaysoni *and* davisoni *approach very closely, or even meet.*

[*Pycnonotus finlaysoni eous*, Khao Yai National Park, Thailand. Photo: Suppalak Klabdee]

The bulbuls have acquired a reputation as boring and wearisome birds, an impression amplified by their unadventurous plumage and brazen ubiquity. One species guilty of bringing the entire family into disrepute is the ***Cream-vented Bulbul****, a bird that might qualify as the embodiment of tedium were it not for its startling eyes. In several bulbuls, uniform coloration is alleviated by a contrasting iris, a recurrent feature that is probably significant in signalling systems, but phylogenetically trivial. The iris in this species is strikingly white, for example, except on Borneo, where a red-eyed morph predominates.*

[*Pycnonotus simplex simplex*,
Singapore.
Photo: Ong Kiem Sian]

details and DNA evidence indicate that they are clearly distinct. Similarly, *tephrolaemus* and *nigriceps*, from western and eastern Africa, respectively, have in the recent past often been considered conspecific, but they differ in several respects, including plumage, behaviour and voice. Molecular data support this separation and, moreover, indicate that *tephrolaemus* is most closely related to *masukuensis*, with which, indeed, it shares some vocal and behavioural similarities, and that these two species form a clade with *montanus*. The relationship between *tephrolaemus* and *nigriceps* therefore appears more distant.

Relationships within the polytypic *nigriceps*, the Eastern Mountain Greenbul, are, however, less clear. Of the six subspecies generally recognized, it has been suggested that, on the basis of genetic distinctness, the three southern races, *fusciceps*, *chlorigula* and *neumanni*, collectively form a separate species from the northern nominate race, *kikuyuensis* and *usambarae*. Since, on the one hand, DNA evidence suggests that further splitting within both groups could also be justified and, on the other, there is a lack of coherent supporting behavioural and, especially, vocal studies, it is nevertheless deemed better to adopt a conservative approach. Similarly, the elevation to species level of one or more subspecies of both Shelley's Greenbul and the Stripe-cheeked Greenbul has also been proposed, but the justification for these treatments is either not clear or, from the evidence hitherto advanced, not convincing.

Although the lowland species of *Andropadus* are less well studied, it seems apparent that their relationship with the montane group is fairly distant; the lowland species are thought to be much

The genus Pycnonotus *was once even more inclusive than it is today, embracing twelve species now placed in* Andropadus. *Although the separation of these two genera is corroborated by plumage, behaviour and ecology, as well as the latest DNA analysis, it seems that* Andropadus *itself is polyphyletic, and thus requires further subdivision. The* ***Little Greenbul****, for example, is essentially a lowland species which, on the basis of bare-part colours, vocalizations and ecology, is only distantly related to its montane congeners. Moreover, its upper mandible bears a number of serrations, which montane forms do not possess.*

[*Andropadus virens virens*,

VIREO]

older, having originated in the early Miocene. Intriguingly, a number of early taxonomic studies placed the montane bulbuls in the genus *Arizelocichla*, on the basis of differences of bill morphology: in particular, these montane forms lack the serrations, or "teeth", on the distal edges of the upper mandible that are present in the lowland species. These older studies also divided the lowland *Andropadus* among up to five separate genera, and it is likely that further phylogenetic work will reveal that the current arrangement is too simplistic. Preliminary molecular data indicate that the Slender-billed Greenbul (*Andropadus gracilirostris*), in particular, is not closely related to any other member of the genus. The Grey Greenbul (*Andropadus gracilis*) and Ansorge's Greenbul (*Andropadus ansorgei*) form a species pair to which the Plain Greenbul (*Andropadus curvirostris*) may prove to be closely related. All three are morphologically and behaviourally distinct from both the Yellow-whiskered Greenbul (*Andropadus latirostris*) and the Little Greenbul (*Andropadus virens*), which, on the basis of bare-part colours, vocalizations and ecology, appear to be most closely related to each other. The relationship of the Sombre Greenbul (*Andropadus importunus*) with its congeners is unclear.

Phylogenetic studies of the genera *Chlorocichla*, *Thescelocichla* and *Pyrrhurus* would also be instructive. In particular, the Yellow-throated Greenbul (*Chlorocichla flavicollis*) appears, from similarities of vocal and other behavioural features, to be more closely related to the Swamp Palm Bulbul (*Thescelocichla leucopleura*) and the Leaf-love (*Pyrrhurus scandens*) than it does to its congeners. In addition, further studies of the relationships of two subspecies of the Yellow-throated Greenbul are called for. In Cameroon, the yellow-throated nominate race is reported as occurring to within 50 km of the white-throated subspecies *soror* in the area of the Adamaoua Plateau. No intergrades are known, and the situation has recently become more intriguing with the realization that there are some vocal differences between them, and with the discovery that populations of the nominate race in Mali do not to respond to playback of the song of *soror*.

The Leaf-love is sometimes included in *Phyllastrephus*, but it differs in not having the long, slender, laterally compressed bill of that genus and in its noisy, extrovert behaviour. The 17 species of *Phyllastrephus* currently recognized are, indeed, remarkably homogeneous in morphology and behaviour. Drably coloured, they are quintessential skulking brown birds of the undergrowth of thickets, galleries, forest edge and, less often, forest interior. The montane Yellow-streaked Greenbul (*Phyllastrephus flavostriatus*) and Grey-headed Greenbul (*Phyllastrephus poliocephalus*) from, respectively, eastern Africa and the Cameroon Highlands form a superspecies and are perhaps the most distinctive. They differ from all others in their conspicuous foraging behaviour, which involves hopping rapidly along horizontal branches, mainly in the middle strata and canopy, peering first over one side and then over the other, and probing periodically. The Yellow-streaked Greenbul is further unusual both in its distinctive habit of deliberately, rapidly and obviously raising and lowering one wing and in its loud song, neither of which is exhibited by the Grey-headed Greenbul. It has been suggested that one or more of the eight subspecies of the Yellow-streaked Greenbul merits species status, with the distinctive brown-headed *alfredi* the most obvious candidate; this, however, differs little vocally from the other subspecies and, biogeographically, it is sandwiched between grey-headed races to the north and south. The case therefore seems unproven, but is worthy of further study.

Presenting considerable identification problems, the Icterine Greenbul (*Phyllastrephus icterinus*) and Xavier's Greenbul (*Phyllastrephus xavieri*), a sympatric species pair, are the only two members of the genus commonly found in the lowland rainforests of West and Central Africa. Also distinct in the amount of yellow in the plumage, they have sometimes been placed in a separate genus, but this seems unwarranted. The relationship of the Icterine Greenbul with two other pycnonotids, tentatively treated as full species, requires investigation. The first of these is the Liberian Greenbul (*Phyllastrephus leucolepis*), known only from a unique type specimen and some field observations of a few other individuals at the type locality, in eastern Liberia. Apart from the distinctive subterminal row of whitish spots on the primaries, secondaries, greater wing-coverts, alula and median and greater primary coverts, from which it takes its alternative name of Spot-winged Greenbul, it is morphologically identical to the Icterine Greenbul. Were it not for the observations of its collector, W. Gatter, who reported that the bird, when foraging, appeared to flick both wings at the same time, holding them partly open, which he interpreted as a possible visual signal, one would be tempted to treat the Liberian Greenbul as an aberrant Icterine Greenbul. The other species is Sassi's Olive Greenbul (*Phyllastrephus lorenzi*), the most distinctive features of which, the head colour and pattern, seem to intergrade with those of the Icterine

The genus Chlorocichla *contains a relatively well-defined grouping of six African species. All are bulky, dull-coloured bulbuls with strong bills and sturdy legs. The* ***Yellow-bellied Greenbul****, perhaps the most familiar species in the genus, is distributed from Somalia to South Africa down the eastern seaboard, where it tends to be common in coastal habitats. Like its congeners, it avoids tall forest, but thrives at forest edges, or in more open brushland and savanna. This individual is visiting a thorn-scrub watering-hole to quench its thirst.*

[*Chlorocichla flaviventris flaviventris*, Mkuzi Game Reserve, South Africa. Photo: Hanne & Jens Eriksen]

The genus Phyllastrephus *contains 17 species, most of which are semi-terrestrial (the name itself, meaning "leaf-tosser", is fairly appropriate). The* ***Terrestrial Brownbul*** *is a typical example. It spends much of its time noisily scratching about in leaf litter with its bill and feet. Although most often found at or near ground level, it is sometimes found up to 12 m higher, probing into dead-leaf clusters and creeper tangles. Like its relatives it is drably coloured, and lives in groups in scrub and woodland understorey, where it is retiring and difficult to see.*

[*Phyllastrephus terrestris terrestris*, Nature's Valley, Southern Cape, South Africa. Photo: Geoff McIlleron]

Greenbul where the two co-occur in eastern DRCongo. Otherwise differing only in its darker overall coloration, it may prove to be a melanistic form of *icterinus* (see also Morphological Aspects). Resolution of these two puzzles must await further study, particularly of vocal and DNA data.

The Toro Olive Greenbul (*Phyllastrephus hypochloris*) has, in the past, been treated as a subspecies of Baumann's Greenbul (*Phyllastrephus baumanni*). Even on morphological grounds this seemed inappropriate; now that the vocalizations of both are known, there can be little, if any, justification for it. In a similar instance, Fischer's Greenbul (*Phyllastrephus fischeri*) has been considered a subspecies of Cabanis's Greenbul (*Phyllastrephus cabanisi*). The two differ, however, in several respects and have recently been found to occur sympatrically, and been observed together in mixed-species flocks, in the Udzungwas, in Tanzania. The subspecies *placidus* of Cabanis's Greenbul has sometimes been treated as a separate species, but it is vocally very similar to the latter and, furthermore, it has been shown that *placidus* from Malawi reacts strongly to tapes of the voice of *cabanisi* from Zambia.

The genus *Bleda* has undergone revision over the last decade or so. Acoustic and morphological studies carried out by C. Chappuis and C. Érard showed that the taxa *notatus* and *ugandae*, hitherto treated as subspecies of the Green-tailed Bristlebill (*Bleda eximius*), were, in fact, more closely related to the Grey-headed Bristlebill (*Bleda canicapillus*). These authors went further, however, and proposed that *notatus*, with *ugandae* as a subspecies, warranted recognition as a full species, forming a superspecies with the Grey-headed Bristlebill. As a result, the Green-tailed Bristlebill became monotypic and was suggested as forming a species pair with the Red-tailed Bristlebill (*Bleda syndactylus*). This arrangement has been questioned by the recent findings of

The ***Northern Brownbul*** *resembles the Terrestrial Brownbul* (Phyllastrephus terrestris) *in appearance, behaviour, and choice of habitat, both being found in a variety of dense thickets. Naturally, they are often confused where their ranges overlap in parts of coastal Kenya and north Tanzania. The Northern Brownbul is slightly smaller and warmer brown above, generally lacking olive tones. It also has a duskier throat than its southern counterpart. They are most easily distinguished by voice, the song of the Northern being a harsh penetrating chatter, faster in pace and higher in pitch than that of the Terrestrial.*

[*Phyllastrephus strepitans*, Athi River, Kenya. Photo: Morten Strange]

P. Beresford, whose molecular studies indicate that *syndactylus* is, rather, the sister-taxon to the rest of the genus as a whole. In addition, her data, while supporting species rank for *notatus*, suggest that *ugandae* may also merit full species status in its own right. Although there is some morphological and vocal evidence in support of this, it is not unequivocal, and further field studies are needed before this step is taken.

Until recently, five African and six Asiatic bulbuls were united in the genus *Criniger*, but this was increasingly seen as an incongruous grouping. Major differences in morphology, voice and behaviour suggested that the two sets of species did not share a recent ancestor. DNA analysis has revealed that the expanded genus *Criniger* proposed by Delacour in 1943, and by Rand and Deignan in 1960, was indeed polyphyletic. On this basis, the Asian species warrant separation in a genus of their own, for which the name *Alophoixus*, erected by E. W. Oates in 1889, is available.

Within *Criniger*, now restricted to Africa, the White-bearded Greenbul (*Criniger ndussumensis*) was formerly regarded as a subspecies of the Yellow-bearded Greenbul (*Criniger olivaceus*). Notwithstanding the vocal similarity between the two, however, the differences in coloration are considerable, such that it seems difficult to argue for their conspecificity. Indeed, the majority of modern authors have treated these bulbuls as two separate species. Recent DNA analyses have supported this view, and have even led to the rather surprising conclusion that *olivaceus* appears to be sister-taxon of the Red-tailed Greenbul (*Criniger calurus*), rather than of *ndussumensis*.

As for *Alophoixus*, taxonomic conundrums abound. The White-throated Bulbul (*Alophoixus flaveolus*), the Puff-throated Bulbul (*Alophoixus pallidus*) and the Ochraceous Bulbul (*Alophoixus ochraceus*) contain a range of confusing forms, the allocation of which to species has fluctuated over the years. The situation becomes especially complex in parts of South-east Asia, and the current delimitation and assignment of subspecies is tentative at best. A full review is required, particularly in south Myanmar, where the patterns of distribution and variation are poorly understood. Two of the remaining three members of the genus, Finsch's Bulbul (*Alophoixus finschii*) and the Yellow-bellied Bulbul (*Alophoixus phaeocephalus*), seem rather divergent in terms of morphology, behaviour and voice, and possibly deserve to be isolated in monotypic genera.

Another classic case of bulbul systematics and nomenclature being dogged by chronic confusion is provided by the generic name *Ixos*. Originally instated by C. J. Temminck in 1825, based on his "*Turdus phoenicopterus*", it was Deignan who, in 1942, reported that the name *Ixos* was invalid owing to its type species being not a bulbul, but a campephagid. Deignan employed the name *Microscelis* as the next oldest valid name applicable to the group. He had considered *Hypsipetes*, erected by N. A. Vigors in 1831, to be preoccupied by a lepidopteran genus described in 1829, and therefore unavailable. It eventually transpired, however, that the supposed preoccupant was spelt as "*Ypsipetes*", and that *Hypsipetes* was therefore a valid name, and *Microscelis* its junior synonym. As such, when Rand and Deignan undertook the biggest review of the family to date, in 1960, they used the name *Hypsipetes* for their expanded genus. More recently, it has been shown that the type of *Ixos* is, in fact, a bulbul after all, and thus *Ixos*, being an older name, has priority over both *Microscelis* and *Hypsipetes*. In any case, the priority of one name over another is no longer relevant as recent work suggests that the best treatment is to subdivide this group once again into its constituent parts, as to do otherwise would render it polyphyletic. Hence, there are now nine species in *Ixos* and seven in *Hypsipetes*, with *Microscelis* as a monotypic genus containing the Brown-eared Bulbul (*Microscelis amaurotis*).

By enlarging *Hypsipetes*, Rand and Deignan gathered a motley band of bulbuls into a single genus in an attempt to solve, or at least to gloss over, the systematic problems posed by this heterogeneous group. As it happens, several taxa sat rather uncomfortably in their sequence, and they have been subsequently removed. In 2002, E. C. Dickinson and S. M. S. Gregory stated that "In addition to *affinis* and *ictericus* the peculiarities of *thompsoni* stand out"; they place these three in the respective genera *Thapsinillas*, *Acritillas* and *Cerasophila*, an arrangement which seems at present to be the most sensible. In addition, further to the resurrection of *Ixos* and *Microscelis*, three more small genera are now usually removed from *Hypsipetes*: *Tricholestes* (one species), *Iole* (three species), and *Hemixos* (three species).

Most of these groups are unlikely to remain stable in their current format. The structure and content of *Ixos*, for example, appears to require modification. The inclusion in this genus of the Sulphur-bellied Bulbul (*Ixos palawanensis*) and the Nicobar Bulbul (*Ixos nicobariensis*) seems tentative at best, and a more thorough review of voice and morphology, coupled with genetic analysis, will probably result in their removal, perhaps to monotypic genera. In addition, justification can be made for elevation of the taxon *cinereiceps*, from the Philippine islands of Tablas and Romblon, to the rank of full species, distinct from the Streak-breasted Bulbul (*Ixos siquijorensis*), since it differs from the latter significantly in voice and morphology. Given that the

The genus Bleda *includes four understorey species known as bristlebills. Ecologically, they are perhaps the closest African equivalent to the swarm-following Neotropical antbirds (Thamnophilidae). Interestingly, the bristlebills have patches of bare bluish skin around the eyes, similar to those found in the antbird genera* Myrmeciza *and* Rhegmatorhina. *While these are much reduced in the nominate race of the* ***Lesser Bristlebill****, it has bright yellow loral spots which, when prominently displayed, stand out like headlamps on the forest floor.*

[*Bleda notatus notatus*, above Etome, Mt Cameroon, Cameroon. Photo: Doug Wechsler/ VIREO]

*The **White-throated Nicator** is one of three species in the genus* Nicator*, the taxonomic placement of which is hotly disputed. It has traditionally been placed alongside the bush-shrikes (previously Laniidae, now Malaconotidae), but recent treatments have grouped it with bulbuls, and its position continues to vacillate between these two options. Evidence for each is equivocal, and some features of* Nicator *are unique. It comes as no surprise, therefore, that recent DNA analysis suggests that* Nicator *is closely related neither to the bulbuls nor to the bush-shrikes, but likely deserves a family of its own.*

[*Nicator gularis*, near Marromeu, Mozambique. Photo: Hugh Chittenden]

Streak-breasted Bulbul is already considered globally Endangered, the two species resulting from such a split may warrant a higher category of threat, especially *cinereiceps*, as the native forests and scrublands of Tablas and Romblon are small and dwindling (see Status and Conservation).

The "*Thapsinillas affinis* complex" in the Wallacean islands of Indonesia presents a knotty problem. The geographical distribution of distinctive characters is unusual. For example, the forms in Seram and the Sula Islands share the feature of yellow in the tail, but an intervening form on Buru lacks this character; meanwhile, both the Buru and the Seram forms have yellow lores, a feature lacking in the Sula population. Such irregular variation renders this complex difficult to review. Nevertheless, the songs of the Seram, Ambon and Buru populations exhibit very considerable differences from the songs of other races to the north and west, such that the former can be separated as the Southern Golden Bulbul (*Thapsinillas affinis*), and all the latter lumped as the Northern Golden Bulbul (*Thapsinillas longirostris*). In truth, these resultant taxa will almost certainly require further subdivision, in view of significant differences between the various island populations. Nonetheless, our preference is to separate them as a preliminary measure, drawing attention to the broadest rift in the complex, and paving the way for appropriate fieldwork and research into the song, morphology and genetics of all taxa involved. If separated as full species, some island races would prove to be very rare. In particular, the divergent form on Sangihe Island (*platenae*) is restricted to a tiny area of ridge forest on Gunung Sahengbalira, where it is thought that only 20–230 individuals survive. In such cases, taxonomic review is vital for the compilation of a realistic conservation strategy for Wallacea, and must be made a priority.

After the excision of so many disparate forms, the genus *Hypsipetes* now contains a relatively homogenous grouping of species, known collectively as the "black bulbuls." At its most inclusive, *Hypsipetes madagascariensis* served as a holding bay for all forms of black bulbul, spanning the Indian Ocean and continental Asia, from Madagascar to central China, but it is now widely accepted that the Malagasy and Asiatic forms represent separate lineages.

On the Asiatic mainland, all forms have traditionally been lumped under the name *Hypsipetes leucocephalus*, an assemblage that will probably be broken up into three or more species when more data becomes available. At the moment it seems safe to treat the isolated races in southern India (*ganeesa*) and Sri Lanka (*humii*) as the Square-tailed Black Bulbul (*Hypsipetes ganeesa*), although vocal differences between them suggest that two species may be involved. The white-headed races breeding in China (*stresemanni*, *leucothorax* and *leucocephalus*) are possibly distinct from adjacent black-headed forms (e.g., *sinensis*, *ambiens* and *concolor*), but, given the complexity of the situation, and the lack of pertinent information, all are retained within the Himalayan Black Bulbul (*Hypsipetes leucocephalus*). A full review of genetic, morphological, vocal and behavioural variation within this grouping is required, along with an analysis of hybrid zones.

The Malagasy lineage can be subdivided, on the basis of recent evidence, into five species, each confined to a single island, or group of islands. Recent molecular studies have supported the opinion that the Reunion Black Bulbul (*Hypsipetes borbonicus*) is specifically distinct from the Mauritius Black Bulbul (*Hypsipetes olivaceus*), as indicated by differences in their behaviour, voice and eye colour; the molecular data also suggest, however, that the latter is, in fact, sister-taxon to the Madagascar Black Bulbul (*Hypsipetes madagascariensis*). This work has, moreover, helped to resolve further the hitherto confused situation in the Comoros, where the existence on Grand Comoro (Njazidja) and Mohéli (Mwali) of a second *Hypsipetes*, in addition to the undisputed presence of *H. madagascariensis* on all four main islands, has long been contentious. The Comoro Black Bulbul (*Hypsipetes parvirostris*) has had a chequered taxonomic history. Shortly after its initial description, as a full species, from Grand Comoro, it became treated as a hybrid between the Madagascar Black Bulbul and the Seychelles Black Bulbul (*Hypsipetes crassirostris*). Subsequently, all forms of *Hypsipetes* in the Comoros were considered sufficiently distinct in combination from the Madagascar populations of *H. madagascariensis* to merit subspecific rank, for which the name *parvirostris* was used, despite the fact that the type of *parvirostris* was the "aberrant" olivaceous form. Meanwhile, the larger olivaceous *moheliensis* had been described as a subspecies of *H. crassirostris*. It has now been established, however, that the olivaceous phenotype does constitute a separate species, *H. parvirostris*, and that it behaves as a parapatric vicariant of *madagascariensis*, replacing it

Until recently the genus Criniger *united five African and six Asiatic bulbuls, all of them boisterous, group-living forest birds with expressive crests and pale throat feathers that are often puffed out in display. Fieldworkers familiar with both continents, however, noted major differences in morphology, voice and behaviour between the African forms, such as the* ***Eastern Bearded Greenbul****, and the Asian ones, and began to suspect that these groups did not share a recent ancestor. The results of DNA analysis support this view, and the two sets of species are now separated, with the result that* Criniger *is restricted to the Afrotropics.*

[*Criniger chloronotus*, above Etome, Mt Cameroon, Cameroon. Photo: Doug Wechsler/ VIREO]

in montane forest habitats. Furthermore, *parvirostris* on Grand Comoro exhibits some acoustic and size differences from the olivaceous form found on Mohéli, suggesting that the two should be treated as separate species; this is supported by molecular analysis, which indicates that *moheliensis* is not the sister-taxon of *parvirostris*. The present treatment of the two as conspecific is considered provisional, pending a full review.

Another taxon with an unstable taxonomic history, albeit one of where it should best be placed rather than whether it existed at all, is the Black-collared Bulbul (*Neolestes torquatus*). On the basis of its distinctive plumage pattern and coloration, it has also been associated with the malaconotid bush-shrikes and, more recently, with the helmet-shrikes (Prionopidae). Whether the preferred option has been bulbul or "shrike", however, the various authorities have usually regarded their choice as tentative, with D. A. Bannerman going so far as to hedge his bets and call it "Black-collared Bulbul-Shrike". Recent work by R. J. Dowsett and colleagues, covering biology, anatomy and DNA, has shown that *Neolestes* is best kept within the bulbuls, where it represents a deep branch of the pycnonotid clade, and may be either the sister-group of the family as a whole or a member of a larger group of which the bulbuls are only one part. Biologically, aspects of its breeding and vocal behaviour, diet and juvenile plumage all argue firmly against its being a "shrike", and suggest that

The six Asian species once combined with Criniger *revert to the genus erected for them by Eugene Oates in 1889:* Alophoixus. *Four of the six, including the* ***Ochraceous Bulbul****, make up a relatively homogenous subgroup of large bulbuls, with permanently erected crests, and throat feathers almost always puffed out, as if brushed the wrong way. This quartet, the "true"* Alophoixus *bulbuls, are generally common in humid forests across southern Asia, from north India to Vietnam and Bali, where they are noisy and conspicuous components of the middle-storey avifauna.*

[*Alophoixus ochraceus cabanisi*, Khao Pra-Bang Kram Wildlife Sanctuary, Krabi, Thailand. Photo: Suppalak Klabdee]

In many bulbul species elongated filoplumes project inconspicuously from the nape, a feature taken to extremes in the ***Hairy-backed Bulbul****, in which these slender filaments grow up to 50 mm long, making them visible under optimum conditions (such as in this photo). Their function, if any, is unknown, but they might be used in courtship displays. The Hairy-backed Bulbul is aberrant in other ways, and occupies a monotypic genus as a result. It is a dainty species that commonly attends mixed-species flocks in the understorey of evergreen forest.*

[*Tricholestes criniger viridis*, Bentuang-Karimum National Park, Kalimantan, Borneo. Photo: Doug Wechsler/ VIREO]

it is, more probably, a bulbul. This is mirrored anatomically, with the morphology of the syrinx, the skull, the humerus and the carpometatarsus all being counter to a shrike affiliation while not being incompatible with the Pycnonotidae. *Neolestes*, however, lacks the nasal ossification (see Morphological Aspects) characteristic of the family, and this absence is thought to be primitive. The Black-collared Bulbul is therefore, as suggested by Dowsett and co-workers, best considered *incertae sedis* within the Pycnonotidae.

The systematic position of the genus *Nicator* has been open to question ever since J. P. Chapin suggested, in the 1920s, that its affinities might not lie with the shrikes (Laniidae). Since it was first described, in 1870, the genus had traditionally been classified with the shrike family Laniidae, formerly considered to include the malaconotid and prionopid species, among several others, on the basis of similarities in coloration and bill morphology. Chapin pointed out that many of its characteristics were more indicative of the bulbuls. He discussed the ways in which *Nicator* both resembled and differed from bush-shrikes of the genus *Malaconotus*, to which it had traditionally been allied, and compared it also with *Bleda*, the bulbul genus which, he initially thought, it most closely resembled. In the end, however, he did not advocate a change in the status quo, and it was not until Delacour's 1943 revision of the family that *Nicator* was placed in the Pycnonotidae for the first time. Delacour derived *Nicator* from *Bleda*, which he in turn derived from *Phyllastrephus*. Chapin subsequently included *Nicator* with the bulbuls in his 1953 treatise, although he did consider that it was not closely allied to *Bleda*. Thereafter, *Nicator* became increasingly treated as a bulbul in systematic texts and regional avifaunas.

More recently, however, the pendulum has started to swing back in favour of treating *Nicator* as a bush-shrike. This follows the studies of S. Olson, who reported that *Nicator* lacks the diagnostic pattern of ossification in the nostril found in almost all bulbuls, and argued for the return of *Nicator* to the Malaconotidae. As further evidence, it was pointed out that *Nicator* lacks the filoplumes in the nape characteristic of most pycnonotids (see Morphological Aspects) and absent also in bush-shrikes, but that it possesses a patch of bristly feathers between the eye and the gape, lacking in other bulbuls but present in *Malaconotus*. Some similarities in foraging technique between *Nicator* and malaconotid shrikes have also been noted.

There are, however, at least as many differences between *Nicator* and the bush-shrikes as there are similarities, and these are outnumbered by the similarities between *Nicator* and the bulbuls. These include the plumage of *Nicator*, which is soft and abundant like that of the bulbuls, and not hard and dense as it is in the bush-shrikes, while *Nicator* shares with the bulbuls the peculiarity of a gap in the feather tract of the back of the neck (see Morphological Aspects), a feature not present in bush-shrikes; in addition, *Nicator* has eyerings and areas of bare periorbital skin, characters shown by some bulbuls but not by bush-shrikes, it is strongly sexually dimorphic in size, as are many bulbuls but not bush-shrikes, and its vocalizations differ strikingly from those of bush-shrikes but less so from those of bulbuls. Further, analyses of feather proteins and early DNA–DNA hybridization studies both place *Nicator* within the

The genus Iole *contains three nondescript South-east Asian species, typified by the* ***Buff-vented Bulbul****. Anonymously dressed, and lacking a notable song, it is often overlooked or misidentified in the field, until its distinctive call is recognized. It is even commonly confused with sympatric* Malacopteron *babblers, which look vaguely similar. The taxonomic history of this group is rife with shifting treatments and taxa wrongly allocated. To add further confusion, when* Iole *is subsumed in* Hypsipetes*, the name* olivacea *is preoccupied, and* charlottae *takes priority as this species' name.*

[*Iole olivacea charlottae*, Crocker Range National Park, Sabah, Borneo. Photo: Doug Wechsler/ VIREO]

The most common and widespread member of the genus Ixos *is the* ***Mountain Bulbul****, its nine races occurring from the Nepalese Himalaya to the Da Lat plateau of Vietnam. It varies substantially in colour and pattern across this range, but most forms have a beautiful rich pinkish or yellowish bloom to the plumage, which is always soft and dense. They are attractive and confident creatures, elegantly elongated, with relatively long and slender bills, and large square-ended tails. In conduct, however, they have something of the brashness of most bulbuls, and are often found squabbling over berries or roving in small garrulous flocks.*

[*Ixos mcclellandii holtii*, Wuyi Shan, Jiangxi, China. Photo: Forrest Fong]

Pycnonotidae, and several other parameters suggest the same treatment. In truth, however, *Nicator* is unique in a number of features, including its nest structure and its possession of preorbital, as opposed to rictal, bristles, as well as the feathering of the lores, which, in contrast to the bush-shrikes, forms stiff, tufted, differently coloured pads in front of each eye. Arguably, it is also vocally distinct.

In view of this continuing uncertainty and debate, it is perhaps not surprising that the most recent DNA studies have indicated that *Nicator* is not closely related to either the bulbuls or the bush-shrikes, but that it appears to merit family status in its own right. For the time being, however, *Nicator* is retained within Pycnonotidae, pending the publication of further studies.

The islands of Wallacea are populated by a single, morphologically variable bulbul superspecies, often dumped in Hypsipetes *but apparently meriting its own genus. The variation in morphology and voice of different island populations implies that more than one species is involved, but the pattern of variation is confusing. On the basis of a dramatic discontinuity in vocal characters the southern races, from Buru, Seram and Ambon, can be split off as the Southern Golden Bulbul* (Thapsinillas affinis)*, leaving all other forms as the* ***Northern Golden Bulbul****. A detailed complex-wide review of genetics and voice is needed to determine whether further subdivision is necessary.*

[*Thapsinillas longirostris chloris*, Halmahera, Indonesia. Photo: Morten Strange]

Comparative analyses of mitochondrial DNA appear recently to have settled one long-standing taxonomic conundrum, by showing that the Malagasy species placed in the genus *Phyllastrephus* by Delacour, in his 1943 revision of the family, unequivocally do not belong either there or, indeed, within the Pycnonotidae itself. In fact, these studies, particularly those undertaken by A. Cibois and colleagues, have revealed that all these species, together with a number of other endemic genera, including *Oxylabes*, *Thamnornis*, *Hartertula*, *Cryptosylvicola* and *Crossleyia*, form part of a single separate radiation of Malagasy songbirds and do not belong, as had previously been thought, variously with the bulbuls, the babblers and the warblers.

Delacour originally placed five Malagasy species in *Phyllastrephus*, and this treatment was adopted by many subsequent authors; a sixth species, *Phyllastrephus apperti*, was added, following its initial description, in 1972. One of those which Delacour transferred was, in response to studies made in the 1970s, removed to the Timaliidae and reverted to the name by which it had previously been known, *Crossleyia xanthophrys*. Subsequent morphological study of the remaining five argued for their removal from the Pycnonotidae; these species were found to lack any trace of the nasal ossification indicative of the family, and they differ osteologically in other ways, too. The more recent molecular evidence has substantiated this and thereby removed the problem of having to explain how a sedentary forest passerine such as *Phyllastrephus* could occur in both Africa and Madagascar. These studies have further demonstrated that the Malagasy "*Phyllastrephus*" are themselves polyphyletic, such that *madgascariensis* should be placed on its own in the genus, *Bernieria*, with the four others, namely *zosterops*, *cinereiceps*, *apperti* and, by inference since no material was available for study, *tenebrosus*, forming a monophyletic group. These four revert to the genus *Xanthomixis*, first erected by R. B. Sharpe in 1881, but long lost in synonymy.

As mentioned at the beginning of this section, these five species are included in the Pycnonotidae merely for reasons of convenience, since the full implications for taxonomy and classification of the discovery of this single separate Malagasy radiation have yet to be realized.

Morphological Aspects

Bulbuls are, typically, slender-bodied, medium-sized passerines with a relatively short neck, wide, rounded wings and a longish

tail. Their legs and feet are usually quite weak, small and short, while the bill, with the conspicuous exception of the two *Spizixos* finchbills, which have a short and stubby bill, is generally of medium length, sometimes shorter, and is slender to moderately thick, the upper mandible downcurved towards the tip, sometimes with serrations and often notched. The operculate nostrils possess a feature common to all "true" pycnonotids except the Black-collared Bulbul, and one which helps to define the family. This is the presence of a thin sheet of bone, or ossified connective tissue, which covers the posterior portion of the nostril. This character is absent in the genera *Nicator*, *Bernieria* and *Xanthomixis* (see Systematics).

In size, bulbuls vary from the dainty, warbler-like Tiny Greenbul (*Phyllastrephus debilis*), 13 cm long, to the heavy-bodied Straw-headed Bulbul, which, at 29 cm, is double the size of many of its co-familials. The sexes of all pycnonotids are generally alike, although females tend to be smaller than males. In the genera *Pycnonotus*, *Hypsipetes* and *Neolestes* these size differences may be minor, at best, while in others they are considerable. In some *Phyllastrephus* greenbuls the differences are sufficiently great that the two sexes have been described as functioning as separate "ecological species", while the males of the Western Nicator (*Nicator chloris*) and the White-throated Nicator (*Nicator gularis*) may be 35–50% heavier than the females. Immatures are unspotted and resemble the adults, but are generally duller in coloration. Young bulbuls, in common with many passerines, tend to have relatively narrow and less paddle-shaped rectrices, with distinctly pointed tips at the shaft.

The plumage of bulbuls is often long, soft and fluffy, particularly on the lower back and rump. Indeed, the name *Pycnonotus* means "dense-backed" and is thought to be a reference to the feathering in this region. By contrast, the cervical region of the spinal tract is usually bare of all except downy feathers, and this is sometimes apparent in the field when the neck is stretched. The skin is typically rather thin; when handled, many pycnonotids will shed feathers readily, although this appears to be more true of the forest species than of the open-country ones. The crown feathers of some species are elongated to form a conspicuous permanent crest, while in others they are partially erectile and are used in display, appearing rather long and unkempt at other times. Similarly, the throat feathers of *Criniger* and *Alophoixus* are also erectile and may be puffed out as a contact signal or in display.

Many bulbuls have bristles, or filoplumes, of unknown function, growing from the nape. In some species these are short and hard to detect, whereas in others they are long, up to 50 mm in the case of the Hairy-backed Bulbul (*Tricholestes criniger*), and fairly conspicuous and can sometimes be seen in the field. These nuchal filoplumes have sometimes been considered a family character, but they are absent in a few species, such as the Black-collared Bulbul, in addition to which they are not restricted to the Pycnonotidae.

Bulbuls possess ten primaries, with P10 often short and no more than about half the length of P9. The tail consists of twelve rectrices and may be square-ended, rounded or, more rarely, graduated. Although some species are strikingly coloured, with bright yellows contrasting with black, these are the exceptions and the plumage coloration comprises, for the most part, sombre combinations of dull greens, browns, greys and yellows, each of which is often prefixed by the word "olive". Contrast may be provided by bright yellow or white, variously on the throat, the tail tips or the outer tail feathers or as spotting on the wings. Some species have contrastingly coloured vent or rump feathering. For example, the back and rump feathers of the Black-headed, Andaman, Grey-headed, Yellow-wattled (*Pycnonotus urostictus*) and Puff-backed Bulbuls (*Pycnonotus eutilotus*) have striking pale tips and black bases. These feathers are used in signalling displays (see Breeding), which involve the raising and puffing-out of the rump feathers, at which time they appear strikingly barred. When the bird is at rest, the dark bases are invisible and the rump and lower back look almost uniform in colour. To what extent this distinctive morphological feature contains useful phylogenetic information is unknown, but it seems likely that the "bar-backed" species are more closely related to each other than the current sequence implies. At the moment they are separated by a broad swathe of plain-backed congeners, an improbable discontinuity that needs to be addressed when the genus *Pycnonotus* is reviewed and subdivided.

Most bulbuls appear to undergo a complete body moult after breeding, although there may be overlap in the timing of the two events. Some species begin the moult before they have completed breeding, while the timing of moult of some others, such as the

*The **Brown-eared Bulbul** is one of the most abundant and familiar birds throughout much of Japan, where it thrives in a wide variety of habitats including suburban gardens and even city centres. Long embraced by an inclusive* Hypsipetes, *it is now considered divergent enough for isolation in a monotypic genus. In evolutionary terms, it is probably closest to the "black bulbuls", in other words to the core of species to which an exclusive* Hypsipetes *contracts. Like several "black bulbuls", it is large and long-winged, capable of sustained flight, and also highly gregarious in the non-breeding season.*

[*Microscelis amaurotis amaurotis*, Yamagata, Japan. Photo: Hirozo Maki]

The genus Hemixos *is sometimes viewed as one variable species. However, its constituent taxa can be grouped into three distinct subgroups, each of which is vocally and morphologically distinct, suggesting that it is best viewed as a superspecies made up of allospecies. One of these, the* ***Chestnut Bulbul****, differs chiefly in its rich rufous upperparts, but this race is further distinguished by the lack of green or yellow tones in the plumage. In general structure, all* Hemixos *bulbuls are similar, with slim bills, erectile crests and pronounced rictal bristles, these last perhaps being an adaptation for flycatching.*

[*Hemixos castanonotus canipennis*, Tai Po Kau spur, Hong Kong. Photo: Martin Hale]

Cape Bulbul, varies individually and no correlation between moult and breeding season is found. The majority of species moult the flight-feathers symmetrically in regular descendant fashion, with usually two but sometimes three feathers in simultaneous growth. In Sarawak, M. P. L. Fogden found that the moult of the Yellow-vented Bulbul (*Pycnonotus goiavier*) lasted roughly 17 weeks, as did that of the Olive-winged (*Pycnonotus plumosus*), Asian Red-eyed and Spectacled Bulbuls (*Pycnonotus erythrophthalmos*), whereas he recorded 20 weeks for the Puff-backed Bulbul, 21 weeks for the Grey-cheeked Bulbul (*Alophoixus bres*) and 23 weeks for the Yellow-bellied Bulbul. Studies by D. B. Hanmer in Malawi and Mozambique revealed similar durations for African species, with primary moult taking 12–16 weeks in the case of the Sombre Greenbul and the Terrestrial Brownbul (*Phyllastrephus terrestris*) and 16–20 weeks in the Yellow-bellied Greenbul (*Chlorocichla flaviventris*), while in Kakamega, in Kenya, C. F. Mann reported 20 weeks for Shelley's Greenbul and the Plain Greenbul, 15–27 weeks for Cabanis's Greenbul and 13–23 weeks for the Red-tailed Bristlebill. For some species, however, Mann found more extended moult durations, including 30 weeks for the Grey Greenbul, 45 weeks for the Little Greenbul and 44–48 weeks for the Yellow-whiskered Greenbul. There appears also to be significant regional variation; thus, while the Common Bulbul takes 4–5 months to moult its primary feathers in Malawi and Mozambique, it can take 5–9 months in west Kenya. In general, however, the timing and duration of moult may exhibit considerable annual variation, indicating that environmental conditions influence moult strategy.

Head and eye ornamentation and colour appear to be important in bulbul recognition and/or display, but this aspect has been little studied. Many pycnonotids have conspicuously coloured eyes, eyerings, eye wattles, unfeathered periorbital skin or loral spots or streaks. Thus, adults of numerous species, in both Asia and Africa, have bright irides of pearly blue, orange, bright red, yellow or white. In the case of some species, eye colour varies in different parts of the range. For example, adult Cream-vented Bulbuls (*Pycnonotus simplex*) in Peninsular Malaysia have creamy-white eyes, as do some of those in Borneo, but others in Borneo have red eyes; immatures have dull-coloured eyes. Similarly, the Stripe-cheeked Greenbul of the subspecies *striifacies*, in the northern part of the Eastern Arc Mountains of Tanzania, has pale bluish-grey, reddish-brown or, rarely, yellow eyes, whereas those of the race *olivaceiceps* of the southern Eastern Arc Mountains of Tanzania, Malawi and north-west Mozambique are yellow in the southern part of the range and chestnut in the north; the nominate race, from the highlands of south-east Malawi, north-central Mozambique and Zimbabwe, has dull pale grey or brown eyes, but these are offset by a contrasting broken white eyering, conspicuous on the upper eyelid, which the other two races do not have. There are also reports that the eye colour of *olivaceiceps* varies seasonally, changing from orange to pale yellow at the onset of the breeding season, but this has been disputed.

Pycnonotids with dull-coloured eyes, such as the *Andropadus* and *Phyllastrephus* greenbuls and brownbuls, and several members of the genus *Pycnonotus*, tend to have contrastingly coloured eyerings. Two of the four *Bleda* bristlebills have an area of conspicuous bare bluish skin before and behind their reddish-brown eyes, while in the other two species these unfeathered areas are largely absent or reduced. Instead, one race of the third species, also with reddish-brown eyes, has bright yellow loral spots, and the second subspecies has dull yellow loral spots and bright yellow eyes, while the fourth bristlebill species has dark eyes and grey loral spots. These loral spots may be either largely concealed or prominently displayed, according to mood. When displayed, the bright yellow lores of the nominate race of the Lesser Bristlebill (*Bleda notatus*) stand out like headlamps in the gloom of the forest floor when the bird is viewed from the front.

Contrasting facial ornamentation must be of considerable significance, given the number of bulbul species that possess such a feature. One example is the Yellow-eared Bulbul (*Pycnonotus penicillatus*), a distinctive Sri Lankan species with a blackish face, adorned with contrasting bristly yellow ear-tufts and cheek-spots, and a whitish postorbital dot. It also has a distinctive white streak, beginning at the base of the bill and forming upright plumes (or 'horns') in front of the eye. Bulbuls of many species probably use this type of ornamentation in contact, sexual or territorial display, perhaps as signals of specific identity, individual status or quality, but much remains to be learnt about their function. Indeed, appreciation of the full range of facial characters of many bulbuls is relatively recent, and probably remains incomplete. Details of eye colour, eyerings and similar characters are, of course, lost on skins, as a consequence of which the group has, in the past, been poorly served by illustrations based on museum material.

The genus Hypsipetes *is here treated as a complex of seven species (the "black bulbuls"), all of which are conspicuous birds, with long tails, long wings, and red or orange bills. Asiatic forms have traditionally been lumped together as one polytypic species, but the evidence in favour of species status for the isolated taxa in south India and Sri Lanka seems compelling. Aside from their diagnostic unforked tails, both races of the* ***Square-tailed Black Bulbul*** *sound harsher and less nasal than their Himalayan and Chinese relatives. In fact, the voice of Sri Lankan* humii *differs markedly from mainland* ganeesa*, and two species may be involved.*

[*Hypsipetes ganeesa humii*, Sri Lanka. Photo: Greg & Yvonne Dean]

The genus Hypsipetes *contains the only group of true bulbuls to have radiated in the Malagasy realm. Without doubt, the long wings and migratory nature of Asiatic congeners predisposed them to the colonization of oceanic islands. Ancestral forms reached Reunion, Mauritius, Aldabra, Madagascar, the Seychelles and the Comoros. They may have reached continental Africa, but here they would have been out-competed by ecologically similar taxa. The isolated Malagasy populations diverged over time, and are now best viewed as a complex of five species, the commonest and most widespread of which is the* ***Madagascar Black Bulbul****.*

[*Hypsipetes madagascariensis madagascariensis*, Mayotte (Maore), Comoros. Photo: Roland Seitre]

Rictal bristles are prominent in the more insectivorous species. They are particularly long in the Hairy-backed Bulbul and strong in the bristlebills; in the Red-tailed Bristlebill, the longest bristle may be equal in length to the bill. Those of the Asian genus *Hemixos*, which indulge in flycatching more than do most bulbuls (see Food and Feeding), are also well developed. True rictal bristles are poorly developed in the three nicators, and are replaced functionally by preorbital bristles, a feature distinctive of the genus. These are disposed around the leading edge of the eye, in an arc running from behind the supraloral streak to above the rear of the gape. Their shape and orientation, which vary depending on where in relation to the eye they originate, may represent modifications to protect the eyes from possible damage directed downwards and sideways from above the bill, a likely threat to a bird that specializes in feeding on large orthopterans and mantids.

The Black-headed Bulbul manifests some variation in the yellowness of the plumage, which may sometimes have a greenish wash throughout. In addition, it occurs as a rare grey morph, which has a variably slaty neck, breast and belly (see Systematics). This morph, which has been described as a separate species on more than one occasion, is (or was) regularly found in north-east India, but it is very rare in South-east Asia and in the three main islands of the Greater Sundas. Interestingly, it seems to arise much more commonly on small islands. More than half of the individuals on Bawean are grey, as were all those seen on Maratua, off east Borneo. No reason for this distribution of schizochroism has been proposed. In some areas, such as east Thailand, a further morph occurs in which dull orange or yellow-green replaces the yellow.

Another factor, and one which has complicated bulbul taxonomy in Asia (see Systematics), is the tendency for the plumage to fade dramatically with wear and time after death. The comparison of old museum specimens with new material has resulted in the publication of a number of erroneous subspecific descriptions.

At least one instance of apparent melanism among pycnonotids is known. In 1972, a new greenbul, "*Andropadus hallae*", was described by A. Prigogine from a single specimen collected in eastern DRCongo. It has since been concluded that this is a melanistic specimen of the Little Greenbul, which it resembles closely except for being significantly darker overall, with little or no yellow below, and with black, not yellowish-brown, legs and feet. No other example has ever been recorded, despite intensive collecting in the area both before and since that time. It is possible that Sassi's Olive Greenbul, from the same area of DRCongo, may also prove to be a melanistic form (see Systematics).

As a final point of interest, it is perhaps worth making mention of a peculiar morphological deformity displayed by a Brown-eared Bulbul in southern Japan. An individual of this species, captured in the Bonin Islands, had three claws on the first toe of its right foot and two first toes on its left foot. The cause of this physical deformity was not clear.

Habitat

Bulbuls are birds predominantly of the Old World tropics, where they are found in Asia, Africa, Madagascar and the island groups of the western Indian Ocean. A few species have penetrated temperate areas of South-east Asia, the Middle East, southern Turkey and north Africa, as well as the Cape region of South Africa. They are, for the most part, arboreal birds, living in forest, woodland, scrub and thickets.

Relatively few Asian bulbuls live within primary forest, the majority being inhabitants of clearings, edge habitats and scrub. Those that do are largely canopy species, all of which often descend lower at forest edges and in clearings. Only a few, such as the Hairy-backed Bulbul and the *Alophoixus* species, are birds of the middle storey and the understorey.

By contrast, pycnonotids in Africa are quintessential birds of the lowland Guineo-Congolian forest region, both of edge habitats and of the forest interior, where they occur at all levels, from the ground up to the canopy. In areas where there is a variety of habitats ranging from secondary regrowth to relatively undisturbed forest, it is by no means unusual to find more than 20 species occurring in close proximity to each other. They are also among the commonest forest species; the Yellow-whiskered and Little Greenbuls, along with the Olive Sunbird (*Cyanomitra olivacea*), regularly come out in the top five most frequently caught species in netting studies in lowland forest areas. Pycnonotids are also a conspicuous element of the avifauna of montane forests in Africa, and a few species range to over 3000 m in montane shrubland, bracken-briar and bamboo. Similarly, bulbuls are numerous in the forests of the East African coast and its associated woodland and thicket habitats. With the exception of the genus *Pycnonotus*, they have penetrated little into more arid areas.

Only a few members of the family are known to have specialized habitat requirements. In South-east Asia, for example, the Straw-headed Bulbul is virtually restricted to waterside woodland, especially along rivers in tall forest, but not occurring in

The head-pattern of the ***Black-collared Bulbul*** *differs strikingly from all other pycnonotids, prompting some reviewers to consider it a bush-shrike (Malaconotidae) or a helmet-shrike (Prionopidae). However, details of its anatomy, voice, behaviour, diet and juvenile plumage all argue firmly against its being a "shrike", as do DNA data. The best policy seems to be to retain* Neolestes *as* incertae sedis *within the bulbuls, where it represents a deep branch of the pycnonotid clade.*

[*Neolestes torquatus*, Mwinilunga, north-west Zambia. Photo: Jon Hornbuckle]

the forest itself. The Leaf-love is an African species with similar preferences: it inhabits forest-fringed rivers, gallery forest and thicket, penetrating forest only where there are areas of *Raphia* swamp. The Swamp Palm Bulbul, found in the same parts of western and central Africa, is even more tied to swampy areas with *Raphia* and, to a lesser extent, *Elaeis* palms.

Since a large number of species of bulbul are frugivorous and tend to favour the small-fruited tree species common in forest regrowth, many do well in areas of degraded forest. Those inhabiting the forest interior, on the other hand, many of which are insectivores, cope less well in secondary habitats. Again, however, it is the *Pycnonotus* bulbuls that profit most from anthropogenic habitats. As a result of irrigated agriculture and human settlement, which have resulted in the growth of shrubs and trees, members of this genus have colonized many subdesert and desert areas that were previously unsuitable for them.

General Habits

Bulbuls vary greatly in their conspicuousness. Some, including many of the *Pycnonotus* and *Hypsipetes* species, are familiar and conspicuous birds, bold and confiding, and often perching on the tops of bushes, or on fences, wires and similar exposed sites, where they attract attention through their jaunty movements, their loud and persistent calls and their restless behaviour, flying noisily from bush to bush. Others, however, particularly those of African forests and thickets, are much more skulking, often betraying their presence only through their vocalizations. Some Asian pycnonotids are similar in keeping to forest undergrowth, although almost all are less retiring than their African cousins. Perhaps the least conspicuous Asian taxon is Finsch's Bulbul, a dull-coloured bird which lives in the dense canopy of evergreen forest and is rarely heard to call.

Most members of the family confine themselves to relatively short flights. When crossing large clearings, their flight often appears loose and jerky, the wingbeats coming in bursts and the tail switching up and down, especially just before landing. Others are stronger fliers, swift and direct; the action of the Common Bulbul has been described as thrush-like, while the flight of various *Hypsipetes* species, and the Brown-eared Bulbul, is often high, powerful and sustained, with fairly marked undulation. Some races of the Himalayan Black Bulbul are migratory (see Movements) and are thus particularly strong fliers; they fly with a rapid, easy action and travel long distances. J. K. Stanford stated of these birds in Myanmar that "they are the only bulbuls which fly several miles to a feeding place after the manner of Paroquets [parakeets (Psittacidae)]".

A number of pycnonotids which live in small groups, such as the Yellow-throated Greenbul and the Swamp Palm Bulbul, often move in follow-my-leader fashion, in which party-members move in succession, one landing on a perch just vacated by another. Several of the *Phyllastrephus* species are similar in behaviour, and members of parties often appear reluctant to cross a path or other open area and do so only in slow succession one after another, each one pausing before following the one in front. In Asia, *Alophoixus* bulbuls also often follow each other in single file when crossing a clearing, road or river. They, however, appear much more confident, and have often been likened to laughingthrushes because of their habit of roving noisily through the middle storey of forest, creeping and clambering among bamboo, vine tangles and the like.

When breeding, many bulbuls are territorial, although the Yellow-whiskered Greenbul is an exception in those parts of its range where it shows lekking behaviour (see Breeding). The extent to which bulbuls are territorial at other times, however, is not very clear. Some species certainly are. The Simple Greenbul (*Chlorocichla simplex*), for example, vigorously defends its territory of 1–2 ha throughout the year in Gabon. For others, however, the situation is less clear-cut. A good number of pycnonotids, both in Asia and in Africa, seem to occupy a fixed space all year. This is true of *Tricholestes* and *Alophoixus* bulbuls in South-east Asia, as demonstrated, for example, by the repeated recapture within and between breeding seasons of Hairy-backed Bulbuls

The plumage of bulbuls is usually ample, long and soft, particularly on the lower back and rump. Indeed, the name Pycnonotus *itself, meaning "dense-backed", is thought to refer to feathering in this region. Many bulbuls raise or spread these feathers as part of courtship displays, or during bouts of sunbathing, as illustrated by this* **Red-whiskered Bulbul**. *This species, an offshoot of the* Pycnonotus *clade, and best-known occupant of the subgenus* Otocompsa, *is striking in pattern, jauntily crested and generally rather slim and erect in stance. As with other bulbuls, the puffing out of its dense body plumage can produce a much more rotund impression.*

[*Pycnonotus jocosus*, Tai Po Kau, Hong Kong. Photo: Martin Hale]

at Pasoh, in Peninsular Malaysia. Studies in Gabon have revealed the same thing for *Criniger*, *Bleda* and *Phyllastrephus* species, as illustrated by the ant-following Red-tailed Bristlebill. This species appears to be territorial throughout the year, but the territories overlap; in areas where ants are common, individuals may have home ranges rather than defended territories. More than one pair or family group may be found around ant swarms, where a dominance hierarchy seems to be established, with dominance at any one time determined by the individual or pair the home range of which is occupied by the ants; owners keep the best vantage points for themselves. Ringed individuals did not follow ants for more than 200 m. In areas where or at seasons when there are few ant swarms, pycnonotids may be more strictly territorial. The Icterine Greenbul is another species which exhibited marked site-fidelity in Gabon; of 64 individuals ringed, 36 were recaptured at least once in the same place, with one being recaught seven times in 66 months and another on twelve occasions in 90 months. Fidelity is shown not only to location but also to partner; both members of a pair were recaught together in the same mist-net after 6, 7 and 61 months. For many of these species, however, typical defensive territorial behaviour, involving contests and vocal activity, has not been observed. Whether these "fixed spaces" and their resources are defended, and so merit the term "territory", remains to be discovered.

Although territorial during the breeding season, some members of the family certainly are not so at other times, and will flock together to varying degrees. Some species, such as the Himalayan Black Bulbul and the Red-vented Bulbul, may form flocks of over 100 individuals in the non-breeding season or when on passage. In Hong Kong, Red-whiskered Bulbuls have also been recorded in non-breeding flocks of up to 200, sometimes mixed with Red-vented Bulbuls, although groups of 20–30 are more usual. The Light-vented Bulbul (*Pycnonotus sinensis*) can be even more gregarious; one gathering of 1000 individuals was recorded in agricultural fields around Hong Kong in December, and three migratory flocks, totalling 2500 birds, were seen in flight over that city in April. White-eyed Bulbuls will also gather together at locally abundant food sources, with flocks of 25–40 recorded in Jordan, and of several hundreds, even thousands, in Israel, at the end of the breeding season, when up to 83% of such flocks comprise first-year birds. Similarly, Common Bulbuls collect in large, loose noisy foraging parties of up to 100 individuals

during the non-breeding season, as do Cape Bulbuls, in the latter case typically of 5–9 birds, although up to 40 may gather at fruiting trees. The Sombre Greenbul is also reported as forming large flocks in the non-breeding season.

Many members of the Pycnonotidae live in small family groups, but the Spotted Greenbul (*Ixonotus guttatus*) is probably the most constantly gregarious of all bulbuls, occurring in monospecific flocks of 5–50 individuals in all months of the year. In general, however, large single-species flocks of bulbuls are exceptional, and much more frequent is the habit of associating with other species in mixed flocks at fruiting trees and at other food sources. This behaviour is widespread in both Africa and Asia. In the Sundaic region of Asia, for example, several species of *Pycnonotus*, such as the Black-and-white Bulbul, the Puff-backed Bulbul, the Asian Red-eyed Bulbul and the Spectacled Bulbul, will gather at sources of fruit. Here, a fruiting shrub, or trees covered in masses of figs (*Ficus*), may be visited in a day by hundreds of birds, the majority of which are often bulbuls, augmented by smaller numbers of flowerpeckers (Dicaeidae), leafbirds, barbets (Capitonidae), orioles (Oriolidae) and others. Similar gatherings are a familiar sight in African forests, where up to six species of *Andropadus* greenbul, Golden Greenbuls (*Calyptocichla serina*), Honeyguide Greenbuls (*Baeopogon indicator*), Spotted Greenbuls, Common Bulbuls and others may come together in large numbers over the course of a morning in order to gorge on ripe figs, along with hornbills (Bucerotidae), turacos (Musophagidae), pigeons (Columbidae), barbets and tinkerbirds, starlings (Sturnidae), malimbes (*Malimbus*) and other frugivores. Much as these gatherings are common occurrences, they are not true mixed-species flocks. They are temporary aggregations at concentrated food supplies, the birds moving independently when they leave the food source.

More permanent are the groupings of understorey species which roam humid forests, mostly in search of insects. In lowland forests of Africa, bulbuls may form the majority in these associations, with the Icterine Greenbul one of the most regular elements. In a study of 228 multi-species flocks in Gabon, by A. Brosset, this species was positively recorded in 156 flocks and may well have occurred in more, while the Red-tailed Greenbul was recorded in 104 and the Lesser Bristlebill in 72. In these flocks, bulbuls never fulfilled the role of "leader" but were always followers, and generally hunted insects disturbed by the passage of the leader, often a mammal such as a duiker (*Cephalophus*).

In Asia, too, Hairy-backed Bulbuls are regular followers in these groupings, as are Yellow-bellied Bulbuls, searching for insects flushed by the foraging party, and harvesting small berry-bearing shrubs and vines as they go. These flocks tend not to be centred around bulbuls, but around babblers, with various species of *Malacoptilon*, *Stachyris* and *Trichostoma* forming the core. The middle storey is frequented by noisy groups of other *Alophoixus* bulbuls, sometimes joined by *Malacoptilon* babblers and *Garrulax* laughingthrushes in roving mixed-species aggregations.

H. E. McClure studied mixed-species flocking by forest birds at Gombak, in Peninsular Malaysia, and came up with some conclusions of interest regarding bulbul behaviour. A total of 89 bird species was counted in 74 mixed-species flocks. Nine species were in more than 25% of flocks and were thought therefore to be regular flock-members; these consisted of leafbirds, minivets (*Pericrocotus*), orioles, babblers, flycatchers (Muscicapidae), drongos (*Dicrurus*) and warblers, but none of the nine was a bulbul. Bulbuls as a whole were found in 38 of 74 flocks at one site and in 34 of 80 flocks at another site, which equates to a presence of, respectively, 51% and 42%. Given the general abundance of bulbuls in Malaysia, this is a fairly clear representation of their general non-attendance of mixed-species flocks, as opposed to gatherings at fruiting trees, in almost 100% of which they are present. Similarly, J. K. Stanford watched mixed-species flocks in evergreen forest in north Myanmar and counted twelve genera of birds that were common attendees of these flocks, none of which was a bulbul. He did, however, mention that bulbuls gathered at flowering rhododendrons (*Rhododendron*) and fruiting trees, converging on these from miles around.

In McClure's Malaysian study, the most frequent attendee in terms of proportion of individuals observed was the Hairy-backed Bulbul: of 41 individuals encountered, as many as 28, or 68%, were in flocks. It is of note that this is one of the most insectivorous of pycnonotids, which probably helps to explain its attendance of mixed-species flocks of insectivores. Other species were usually found away from flocks, as instanced by the fact that only 21% of Asian Red-eyed Bulbuls found were in flocks, the corresponding figure for Grey-cheeked Bulbuls being 37% and for Streaked Bulbuls just 7%. A similar study at a slightly higher

Bulbuls spend a good deal of their time preening, in order to maintain the quality of their plumage. Flocking species tend to synchronize their bouts of comfort behaviour, often perching together and preening through the middle of the day. The same type of synchronization applies to less gregarious species, such as the ***Orange-spotted Bulbul****, pairs of which often preen in close proximity. Be that as it may, reciprocal preening, or allopreening, has never been reported in any member of the family.*

[*Pycnonotus bimaculatus*. Photo: Brian J. Coates]

Most bulbuls are, to a greater or lesser degree, social birds. Pair members spend much time consorting, often with little regard for personal space, and many species join flocks. The ***White-eyed Bulbul*** *is monogamous in the breeding season, but scores of individuals gather at prime sites during winter, while at the end of the breeding season flocks of thousands have been recorded, mostly comprising first-year birds. The bulbuls known to congregate in large single-species associations are outnumbered by those that join mixed-species flocks, either of foraging insectivores or of frugivores concentrated at locally abundant food supplies.*

[*Pycnonotus xanthopygos*, Israel. Photo: Duncan Usher/ Ardea]

altitude in the same watershed revealed that Scaly-breasted Bulbuls moved through the canopy in loosely knit but organized parties, which often came into contact with the permanent assemblages of insectivores. Of 80 mixed flocks watched, these bulbuls were part of 20, but they were only a temporary ingredient, tending to converge when fruit trees were in the vicinity and moving off again later. The author assumed that the bulbuls were eating only fruit, and may not have noticed that they gained some advantage by temporarily foraging on insects.

During the breeding season, many bulbuls are very aggressive (see Breeding). They can be equally so when feeding together with other species. Those which attend driver ant swarms (see Food and Feeding) often demonstrate intraspecific and interspecific aggression as a means of establishing dominance hierarchies. In Africa, for example, the Grey-headed Bristlebill interacts aggressively with the Red-tailed Bristlebill, the Little Greenbul, the Brown-chested (*Pseudalethe poliocephala*) and White-tailed Alethes (*Alethe diademata*) and the White-tailed Antthrush (*Neocossyphus poensis*). These noisy disputes involve loud singing and the spreading of the tail feathers, displaying their yellow tips, and chasing and violent fights may ensue.

As a further manifestation of their aggressive behaviour, bulbuls are also enthusiastic mobbers of predators, such as hawks (Accipitridae), owls (Strigidae), crows (Corvidae), coucals (*Centropus*), snakes, and such mammals as pangolins (*Manis*), squirrels (Sciuridae) and the like. They are quick to spot a potential threat, and their noisy scolds rapidly attract other birds. A pair of Himalayan Black Bulbuls was watched as the two birds successfully chased a crow away from the nest by bombarding it around the head and calling aggressively; the crow left without stealing the nest contents. Similarly, co-ordinated mobbing by a pair of Yellow-vented Bulbuls in Malaysia was enough to drive off a squirrel from an active nest. In Africa, a Common Bulbul scolded a stuffed Spotted Eagle-owl (*Bubo africanus*) which had been put out in a garden, and, after the owl had been removed, the bulbul even continued to scold the space previously occupied by it. The prize for the most extreme audaciousness goes, however, to a group of Light-vented Bulbuls in south China which was watched as it mobbed a tiger (*Panthera tigris*) so aggressively that the large cat vacated its basking place and sauntered back into the dense woods.

Most information on the roosting behaviour of pycnonotids relates to the gathering of birds in the non-breeding season. For example, reedbed roosts of Yellow-vented Bulbuls in Malaysia can run into the thousands during this period (see Movements). Large communal roosts of this species have also been recorded on several occasions on the Indonesian islands of Bangka, Sumatra and Java, generally in scrub, swampy habitats or strips of woodland near the coast; one roost was in scrub mixed with cane (*Saccharum spontaneum*). One observer counted 512 individuals passing overhead in a ten-minute period, and that in only one direction from the roost. In Borneo, one roost of Yellow-vented Bulbuls in low coastal scrub alongside reedbeds in Sabah was thought to number "several hundreds, possibly thousands". Ashy Bulbuls (*Hemixos flavala*) have also been recorded as roosting communally in the non-breeding season, sometimes favouring bamboo clumps. Red-whiskered Bulbuls, too, roost communally when not breeding. One roost of this species in Hong Kong was in tall grass, which 218 birds were seen to enter in the late afternoon. The Red-whiskered Bulbul has also been recorded as roosting in "thousands" in secondary-forest canopy in Myanmar, where, in addition, huge communal roosts of Red-vented Bulbuls have been noted in canebrakes. In that same country, a "vast gathering" of Himalayan Black Bulbuls, consisting of equal numbers of white-headed and black-headed individuals, was found at a roost in the forest canopy. One radio-tagged Black-and-white Bulbul, followed over a period of seven days, used different roost-sites each night.

Far less is known about the roosting behaviour of this family in Africa. The Common Bulbul roosts in thick foliage, including, in Morocco at least, that of fig trees or orange trees. During the breeding season, one pair in Gabon slept together in the same patch of foliage every night for two months. The Common Bulbul is noted to be one of the last bird species to retire at night and one of the earliest to call in the morning.

Bathing appears to be quite a common habit among bulbuls. The Common Bulbul bathes, sometimes in groups, in rivers, pools, gutters and birdbaths and in rainwater on foliage, and may do so in the morning or the evening. The Yellow-vented bulbul has likewise been reported as foliage-bathing in wet vegetation, and one was watched as it gathered water droplets by sliding down the midribs of banana fronds. Bathing has been reported, too, for

Bathing appears to be a common habit amongst bulbuls, at least those conspicuous species with open-country lifestyles, the details of which, if not exactly better studied, are at least more visible. The available evidence suggests that they bathe sometimes alone, sometimes in groups, in almost any available water, including rivers, lakeshores, puddles, gutters, birdbaths and in rainwater collecting on foliage. One bulbul was watched repeatedly sliding down the midrib of a recently soaked banana-leaf to douse itself. Bathing may take place in the morning or the evening, but the latter seems to be the preference of most bulbuls, especially those that inhabit forest. These have been reported visiting favoured spots for bathing and drinking, daily in the afternoon, often in the company of other forest birds. The act of bathing itself is undertaken much as in any other passerine, except with a higher than average dose of gusto. When it comes to foraging, fighting and singing, what bulbuls lack in subtlety they make up for in enthusiasm, and the same can be said of the way they bathe. A bathing ***White-eared Bulbul*** *first immerses its underparts in water, then flutters its wings vigorously, sending a shower of droplets into the air.*

[Above: *Pycnonotus leucotis mesopotamia*, region of Dubai.

Below: *Pycnonotus leucotis leucotis*, Keoladeo Ghana National Park, Bharatpur, India.

Photos: Roland Seitre]

a number of forest species, such as the Black-and-white and Cream-vented Bulbuls, the Little, Yellow-whiskered, Stripe-cheeked, Shelley's and Eastern Mountain Greenbuls, the Swamp Palm Bulbul, the Icterine and Xavier's Greenbuls, the Grey-headed and Lesser Bristlebills, the Eastern Bearded (*Criniger chloronotus*), Western Bearded (*Criniger barbatus*), Red-tailed and White-bearded Greenbuls, and the Grey-cheeked Bulbul. Many appear to favour an evening bath, in a shaded stream or pool, followed by preening prior to going to roost. Particular spots are often preferred, and several species may come together, with other forest birds, to bathe collectively. Water-filled holes in trees are also used, and foliage-bathing may occur opportunistically after rain. A. Hoogerwerf noted that, in north Sumatra, Asian Red-eyed Bulbuls, along with a range of other pycnonotids, appeared every afternoon at a "bathing-place in a brook running through the jungle". This locality was apparently close to scrub and pasture, and several species of forest and open-country bulbul visited it, together with various other birds, in order to bathe and drink in the afternoons.

It is likely that bathing is combined with drinking, but there are few reports on this. Common Bulbuls and White-eyed Bulbuls, at least, drink regularly in drier areas, by taking water from dripping outdoor taps and by sidling down the stems of reeds and similar plants to sip from the water surface below.

Some pycnonotids are known to indulge in sun-bathing. One Olive-winged Bulbul was watched as it sunned itself on a creeper-covered tree bole, its back exposed to the sun, the wings drooping and the rump plumage fluffed up, holding this position for ten seconds. V. G. L. van Someren described a Common Bulbul that sunbathed by lying on its side, spreading the tail and one wing, raising its crest and fluffing its rump feathers to allow the sun to penetrate. Similar behaviour has been reported for the Yellow-whiskered Greenbul.

Dust-bathing appears not to have been recorded for any member of the family. Anting, on the other hand, has been reported for several species, including the African Red-eyed Bulbul, the Common Bulbul and the Northern Brownbul (*Phyllastrephus strepitans*). In the case of the last-mentioned, two or three individuals were watched as they crouched, wings spread, apparently in a "semi-entranced state" on a sunlit path in the bush where many ants were present.

Voice

Many bulbuls are noisy birds. In both Africa and Asia they contribute a significant proportion of the bird sounds heard in forest-edge and shrubby habitats and, in Africa, in the forest interior, too. Their voices often have a nasal or gravelly quality, some are bubbling and conservational while others are harsh and intrusive, and yet others are pleasant pure whistles. Although the Pycnonotidae are not known for the beauty of their songs or the extent of their vocal repertoires, their voices are, generally, distinctive and provide a reliable means of distinguishing between species of similar appearance. A number of species vocalize for much of the day, especially when in company.

Some bulbuls use prominent perches from which to sing. These include the open-country members of the genus *Pycnonotus*, which choose bushtops or any other prominent perch that presents itself, such as a telegraph pole or wire, a fence or a similar station. Most *Hypsipetes* species also sing from prominent perches, often selecting the very uppermost branches of trees. Many other forest bulbuls sing from lower, rather more concealed perches, while some, such as the nicators and several *Andropadus* greenbuls are real skulkers.

Although the songs of bulbuls are a familiar feature in many habitats, few studies on the full repertoire of vocalizations have been undertaken. One exception is that of A. Kumar and D. Bhatt, who looked at sound production by Red-vented Bulbuls in north India. These ornithologists concluded that this species produces seven types of vocal signal, which they put into the following categories: social contact signals, roosting signals, two types of alarm signal, distress signals, twittering signals and begging signals. They enumerated 18 types of "social contact signal", but these vocalizations are probably not, or not restricted to, contact as they are a little too complex, and many observers would have called them the "song". The function of "song" in many bulbuls, including *Pycnonotus*, is, however, unclear. Phrases seem to be given during much of the day, and it may be that a contact function is dominant. The "roosting signals" were emitted only in the 15-minute period before, or sometimes after, roosting communally in dense trees. The two alarm signals appeared to be differentiated by intensity, type I being given when a predator was nearby and type II when a predator was very close. Following on

In the breeding season bulbuls tend to be pugnacious birds. In the genus Pycnonotus, *their aggression manifests itself in frequent ritualistic displays, and occasional brawls. A common theme is for rivals to stretch upwards, producing garbled or twittered vocalizations, while fanning their tails outwards. When evenly matched, the display of one bird is mirrored by the other, as demonstrated by these* ***African Red-eyed Bulbuls****. The same display is regularly seen if a hapless bulbul comes across his reflection in a mirror, window, shiny hubcap or the like.*

[*Pycnonotus nigricans nigricans*, near Okahandja, Namibia. Photo: Eric & David Hosking/FLPA]

Bulbuls are highly vocal birds, better known for the amount of noise they produce than the beauty of their songs. Many species produce simple, repetitive, jolly phrases at all times of day, and in all seasons, such that it is rather difficult to distinguish to what extent the main vocalization is a true song (or mating signal), and to what extent it functions in contact or cohesion between the members of pairs or groups. In any case, their vocabulary is limited for an oscine. In many bulbuls the quality of voice is somewhat nasal, gravelly or clinking; in others it is bubbling, or chattering, or harsh and intrusive. It may be pleasing to imagine that the ***Brown-eared Bulbul*** *pictured in this beautiful photograph is warbling its sweet song into the wintry snowscapes of Japan, but in reality it is producing one of the most unattractive noises made by any bird. Usually transcribed as "shreep" or "weesp", its main call is loud and unbecoming, and is unleashed remorselessly throughout the year.*

[*Microscelis amaurotis amaurotis*, Yamagata, Japan. Photo: Hirozo Maki]

Apart from the simplistic song of males, the ***Common Bulbul*** *gives a range of quieter vocalizations in different contexts. Individuals produce subdued, buzzy subsongs, for example, and a variety of contact calls. These may be uttered when one pair member is separated from its mate, but also when the two are side by side. In addition, the male gives a short burst of soft chattering calls, or a harder "cheedle-cheedle-cheedletit", when he greets the female, a moment which appears to be captured in the photograph.*

[*Pycnonotus barbatus layardi*, KwaZulu-Natal, South Africa. Photo: Roger Tidman/ FLPA]

from this, "distress signals" were uttered when the bird was actually held by a predator. "Twittering signals" appear to be a subsong, of unknown function, while "begging signals" are calls directed by nestlings and fledglings at parents.

Another study, of three *Pycnonotus* species in South Africa, recognized four types of vocalization. These correspond closely to those of Red-vented Bulbuls. They comprise a territorial song, uttered by the male only and mainly during the breeding season; a subsong, a quiet "swizzling" chatter, given by a resting individual hidden in a tree or shrub; alarm calls of at least two sorts, one for low intensity and a second for high intensity; and contact calls, which are very variable in structure. These contact calls are often uttered during the breeding season when an individual is separated from its mate, and cease when the partners rejoin each other. They were also given when the two were next to each other, however, and may therefore have an additional function of signalling to other, nearby bulbuls. These notes are also used by bulbuls in foraging flocks in the non-breeding season, and may be used by paired individuals for maintaining contact at such times.

In a third study, J. F. M. Horne examined the vocalizations of Mauritius Black and Reunion Black Bulbuls and concluded that at least four main types were made by adults. These were the "chuckle", the "cat call", the soft notes of pair contact, and the stress-induced "kek". In the case of the Mauritius Black Bulbul, the "chuckle" varied seasonally, sexually and according to context, but it formed the basis of a simple song and was used for recognition or greeting between members of a pair. The "kek" is apparently given in situations of both fear and aggression. The soft notes of pair contact, uttered by members of the pair while foraging, comprised quiet, short "chuckle" notes, similar to those used by a group of individuals feeding at a common food source, such as a fruiting tree. This was interpreted as indicating that pair-members maintain contact within a group. When one of the pair rejoined its mate after spending time apart from it, the two would "chuckle" jointly, even though they had been in contact vocally for most of the time. The "cat call", or "mew", is a long, clearly defined note, either given singly or preceded by some form of "chuckle", but no interpretation of its function was made. The same four types of vocalization were found for the Reunion Black Bulbul, but there were differences of detail. The other three *Hypsipetes* species of the Indian Ocean islands share a similar repertoire.

The extent to which other pycnonotid genera, particularly those of the forest interior, have comparable vocal repertoires awaits further study.

Although the song of most bulbul species could not be described as musical, an exception is that of the Straw-headed Bulbul. This Asian species has an intensely powerful song, very fluty and melodious, which is often given as a duet, or even in chorus by a small territorial group of adults. It was described by B. E. Smythies as "a prolonged series of magnificently warbled notes, richer and more powerful by far than the songs of such celebrated performers as the [Common] Nightingale [*Luscinia megarhynchos*] and the [Common] Blackbird [*Turdus merula*], but lacks variety and is always sung *fortissimo*." Unfortunately, this bulbul's voice has been its undoing, as it is so popular as a cagebird in Indonesia and South-east Asia (see Relationship with Man) that it has totally disappeared from the majority of its former range. In Java, its voice was, until recent decades, one of the commonest bird sounds of downtown Jakarta, a result of all the cagebirds on windowsills. The Straw-headed Bulbul is now so rare that it is becoming unusual to see it even as a cage bird.

Another member of the family with a distinct song is the Southern Golden Bulbul, found on three islands in Indonesia. In addition to various chattering calls, it has a loud, mournfully whistled phrase, usually given after some "chacking" notes, which is much more sweet and song-like than the equivalent vocalizations of most bulbuls. It is an inhabitant of dense forest, and song is probably, therefore, more important to it in communication than are visual signals. This species belongs to the genus *Thapsinillas*, traditionally considered monotypic, but geographical variation in song indicates that more than one, and probably more than two, species may be involved.

A few African pycnonotids also stand out for the attractiveness of their songs to the human ear. The two larger *Nicator* species share similar loud, varied songs that have been likened to that of the Common Nightingale or a robin-chat (*Cossypha*). Of the White-throated Nicator in the Usambara Mountains, in north-east Tanzania, R. E. Moreau wrote that "if the singing bird is some distance away, all that can be heard is a periodical burst of liquid throat-notes of a power and richness that in my experience are unsurpassed." He added that the nicator will often sit for a lengthy period in an impenetrable thicket, "making the forest resound every twenty or thirty seconds with the splendid sound. These throat-notes exceed a Nightingale's in volume, but they certainly lack variety."

Flocks of bulbuls can be very noisy, often giving loud chattering vocalizations, basically variants of the "social contact signals" described above. The noise made in the early mornings by

Although some birds seen visiting flowering trees, or even probing their bills into flowers, may be seeking the insects attracted to the nectar source rather than the nectar itself, it nevertheless appears that many bulbuls do harvest nectar supplies. Some species, especially Pycnonotus *bulbuls, and "black bulbuls" in the genus* Hypsipetes*, are often seen with colourful smears of pollen on their foreheads. These inadvertent cargoes suggest an active role in pollination, but it is equally common for bulbuls, especially those with shorter bills, to access nectar by nipping corollas at the base. They glean nectar indirectly, circumventing the plant's pollination system, and are therefore predators, not pollinators. One species commonly reported foraging on nectar is the* ***Red-vented Bulbul****, here pictured at the flowers of a silk-cotton tree* (Bombax ceiba)*. In India it has been reported visiting a wide range of flowering trees, shrubs and epiphytes, alternatively consuming young buds in their entirety, opening mature buds to access nectar, gleaning nectar from open flowers, or simply eating the petals. In Africa the* ***Common Bulbul*** *is also fond of nectar. It is perhaps most often seen at aloes, in this instance a "mountain aloe"* (Aloe marlothii).

[Above: *Pycnonotus cafer bengalensis*, Gauhati, Assam, India. Photo: Roland Seitre.

Below: *Pycnonotus barbatus layardi*, Kruger National Park, South Africa. Photo: Getaway/David Steele/Photo Access]

the "vast gathering" of Himalayan Black Bulbuls recorded at a forest-canopy roost in Myanmar (see General Habits) was likened to the din produced by a huge "murmuration" of Common Starlings (*Sturnus vulgaris*).

Paired individuals of the Yellow-vented Bulbul sometimes indulge in unco-ordinated duetting, one partner giving a bubbling song and its mate joining in with a string of emphatic "treek" notes. Duetting may be performed by other members of the genus *Pycnonotus*, and it has been recorded also for two *Phyllastrephus* species, the Terrestrial and Northern Brownbuls.

Mimicry occurs in the family, but seems to be uncommon. The White-browed Bulbul (*Pycnonotus luteolus*) in India is known to imitate the songs of several species, including the Red-vented Bulbul, the Large Cuckoo-shrike (*Coracina macei*) and the Little Green Bee-eater (*Merops orientalis*). Similarly, in Africa, the Western Nicator will mimic other species, including the Yellow-throated Nicator (*Nicator vireo*), Sjöstedt's Owlet (*Glaucidium sjostedti*), the African Pied Hornbill (*Tockus fasciatus*) and the Yellow-bellied Wattle-eye (*Dyaphorophyia concreta*), and the White-throated Nicator has been recorded as imitating the Moustached Green Tinkerbird (*Pogoniulus leucomystax*) and the Eastern Black-headed Oriole (*Oriolus larvatus*).

Food and Feeding

Bulbuls eat a wide range of foods, including fruits, seeds, nectar, pollen, arthropods and small vertebrates, as well as some carrion and beeswax. As a broad generalization, however, the majority of pycnonotids are essentially frugivores which augment their diet with a certain amount of arthropod food, although a significant minority of species, mostly in Africa and Madagascar, are insectivorous, some with quite specialized niches.

Many of the open-country species are skilled opportunists and extreme generalists. The Yellow-vented Bulbul, for example, has one of the broadest foraging niches yet measured among non-forest passerines. It collects food by (i) consuming a very wide range of fruits and nuts, both native and introduced; (ii) sallying from perches for lepidopterans and termites (Isoptera) and jumping up at them from the ground; (iii) searching foliage and bark for insect larvae; (iv) taking morsels of carrion; and (v) eating flowers and robbing nectar by piercing the base of corollas. The same is true of a number of other *Pycnonotus* species, and several studies have revealed the catholicity of their diets. For example, observations of the Common Bulbul in one area of Zimbabwe demonstrated that more than fifty species of native and introduced fruit were consumed, and another study of this bulbul, in Malawi, recorded 21 species of wild fruit, together with flower parts from at least eight genera, young leaves of acacia (*Acacia*) and nectar from two genera of plants. The range of arthropods taken by this species is equally broad, and includes alate termites, ants, aphids (Homoptera), beetles (Coleoptera), butterflies and moths (Lepidoptera), dragonflies (Odonata), grasshoppers (Orthoptera), mantids, mayflies (Ephemeroptera) and spiders (Araneae), in addition to which its diet also incorporates small lizards and geckos (Geckonidae), as well as beeswax. Similar studies of Cape and White-eyed Bulbuls obtained comparable results.

A study of Red-vented Bulbuls in Haridwar, in northern India, revealed that, of 377 observations of feeding behaviour, 55·9% involved the consumption of ripe fruits and 17% the eating of unripe fruits, with 13·8% directed at nectar and 13·8% at leaves (although these proportions narrowly exceed 100%, and make no mention of invertebrate prey). Elsewhere, an analysis of 528 faecal samples of Red-whiskered Bulbuls in Hong Kong showed that 92% contained seeds or fruit and 19% contained insect remains. These data give some idea of the relative intake of fruit, nectar and insects in the diet of common open-country species. Results were similar for the Light-vented and Cape Bulbuls. Of 414 faecal samples of the former, 96% contained seeds/fruit and 39% contained insect remains, while some 90% of the Cape Bulbul's diet comprised vegetable matter and 10% consisted of arthropods. The daily dry-weight consumption of the latter species averaged about 24% of the bird's own weight.

The means of obtaining food may be as varied as the food sources themselves. S. Ali watched Red-vented Bulbuls on mistletoes (Loranthaceae) and noted that they nipped open mature buds and probed into the exposed corolla tubes for nectar. He observed that some of these birds had a whitish streak of pollen on the head, which attached itself while they fed. This being the case, one can presume that bulbuls actively pollinate some flowering plants. Food is sometimes obtained by piracy. A Red-vented Bulbul in India repeatedly robbed a male Coppersmith Barbet (*Megalaima haemacephala*) as the latter carried fruit with which to courtship-feed his mate. Not only fruit is pirated; White-eyed Bulbuls in Israel have been recorded as chasing Hoopoes (*Upupa epops*) in order to steal mole-crickets (Gryllotalpidae) from them.

Bulbuls also often attend termite emergences. In Malaysia, for example, up to twelve Streak-eared Bulbuls (*Pycnonotus blanfordi*) have been seen together at dusk at such events, catch-

Most bulbuls are chiefly frugivorous, and the ***Sombre Greenbul*** *is no exception. It has been recorded consuming a wide variety of berries and other fruits, mostly in the small size classes. It gathers them while clambering through foliage in the shrub layer or canopy of thickets and woodlands. Berry-bearing trees or shrubs are visited repeatedly. A smaller dietary component consists of arthropods and small gastropods. These are captured in flight, gleaned from foliage, or collected from the ground among leaf litter.*

[*Andropadus importunus insularis*, Athi River, Kenya. Photo: Morten Strange]

*In one Malaysian study the **Puff-backed Bulbul** was observed gleaning figs from most of the 25 species of* Ficus *monitored, targeting fruit 5–15 mm in diameter. The individual pictured here is holding a fig at the upper end of that scale, and it is probably incapable of eating anything much larger. This species is named after the luxuriant plumage of its lower back and rump, which is sometimes raised to reveal contrasting colours. It is the sole member of the subgenus* Euptilosus, *which surely deserves separation from* Pycnonotus, *either independently, or in conjunction with other South-east Asian bulbuls. None seem closely related, but several have similar dorsal plumage.*

[*Pycnonotus eutilotus*, Malaysia.
Photo: Hirozo Maki]

ing flying termites on the wing. This same species has been noted as foraging on the ground in an unusual fashion, by lifting leaves and stones to uncover invertebrate prey with which to feed its fledglings. Some bulbuls regularly feed on the ground. Straw-headed Bulbuls, for instance, often drop from a perch down to rocks or earth banks alongside rivers, and several open-country *Pycnonotus* species feed on the ground as happily as they do in bushes. The Yellow-vented Bulbul often hops about on the ground to feed on worms, scarab beetles (Scarabaeidae), orthopterans and the like; these are struck vigorously against a branch or rock before being swallowed. This species also takes squashed fruit and dead snails from roads, as well as pieces of carrion. Common Bulbuls will regularly patrol the walls of buildings and similar sites soon after dawn, seeking insects attracted there during the preceding night by security lights. The three bulbuls in the genus *Hemixos* seem to perform flycatching more than do the majority of the members of the family; they frequently catch moths and other insects in flight, after having flushed them from hiding places.

Many of the *Hypsipetes* bulbuls are almost as catholic in their choice of food and as opportunistic in their foraging habits as are the open-country *Pycnonotus*. Thus, the Seychelles Black Bulbul has been recorded as eating 22 species of fruit, both native and introduced, as well as a wide range of arthropods and also birds' eggs. It obtains insects by gleaning from branches and trunks and probing in leaf clusters, as well as by snatching them from leaves in swooping flight, and it acrobatically takes winged insects in flight. As its congeners, however, it rarely feeds on the ground. The Himalayan Black Bulbul is inordinately fond of nectar; several individuals will often visit the same large flowering tree and they commonly display a yellow or orange frons, the forehead having become smeared with pollen.

The mainly insectivorous African genera, *Phyllastrephus*, *Bleda* and *Criniger*, are, with some exceptions, birds of the forest understorey and thickets. The name *Phyllastrephus* means "leaf-tosser" and is well given. Most members of this genus glean arthropod food from the ground, among leaf litter, fallen wood and moss, under and through which they poke about in small monospecific groups. They also take food from leaves and tree trunks, to which they may cling with fluttering wings, and occasionally make short aerial sallies. Their food comprises a wide variety of arthropods, including crickets, beetles, mantids, caterpillars, ants, spiders and the like, as well as molluscs and some fruit. The Yellow-streaked Greenbul is an atypical *Phyllastrephus* as it usually forages in the middle and upper strata of forest, where it gleans from leaves, bark, crevices, epiphytes, bundles of dead leaves and similar sites. It is often to be seen on large horizontal branches, from which it peers alternately over one side and then the other as it works along, sometimes hanging off sideways or upside-down in order to reach prey. This greenbul, when foraging, has the distinctive and conspicuous habit of deliberately but rapidly raising and lowering one wing at a time, exposing its yellow underwing-coverts, as when peering beneath a branch. This action may be intended to startle larger insect prey into movement.

Both the bristlebills in the genus *Bleda* and the bearded greenbuls in *Criniger* are regular components of mixed-species foraging flocks. The bristlebills are very much species of the forest floor, and are rarely seen more than a few metres above it. Here, they are extremely regular members of the group of species which feed on arthropods fleeing swarms of driver ants (*Dorylus*). The Red-tailed Bristlebill, the largest species, takes correspondingly large prey, including frogs and toads, in addition to beetles, mantids, termites, cockroaches (Blattodea), cicadas (Cicadidae), centipedes (Chilopoda), millipedes (Diplopoda) and spiders, as well as some fruit. The bearded greenbuls generally forage at slightly higher levels than the bristlebills, and some, but not all, of them regularly attend ant swarms. Two species, the Yellow-bearded and White-bearded Greenbuls, have a distinctive foraging method. They specialize in seeking food on vertical stems and trunks, to which they cling and which they work over, gleaning from the bark and in crevices. This habit, interestingly, is shared with two species unrelated to them, the Western Mountain Greenbul of the Cameroon highlands and Shelley's Greenbul of East Africa, while two of the even less closely related Malagasy tetrakas show rather similar strategies. One of these, the Short-billed Tetraka (*Xanthomixis zosterops*), forages mostly between 0·5 m and 5 m above the ground, by gleaning in the vegetation of small understorey trees; it frequently perches on vertical stems, up which it works rapidly, and makes short flights to catch arthropods so disturbed. The Grey-crowned Tetraka (*Xanthomixis cinereiceps*) specializes on moss-clad vertical stems, trunks and branches less than a metre in width.

*Most open-country bulbuls are hugely successful generalists. The **Yellow-vented Bulbul**, for example, has one of the broadest niches in terms of food and foraging technique of any passerine. Primarily a frugivore, it consumes berries and other fruits, from ground level to the tops of 50-m-tall trees. Small fruits are eaten whole, but larger varieties are picked at and nibbled. It eats seeds, drinks nectar from flowers, and catches a large quantity of invertebrates by jumping and sallying, or gleaning from bark and foliage; it hops on the ground to feed on worms, beetles, crickets, and other insects; it visits bird tables to eat scraps; and it even dines on carrion when the opportunity arises.*

[*Pycnonotus goiavier analis*, Katong, Singapore. Photo: Ong Kiem Sian]

A few African bulbuls have been recorded as perching on antelopes, where they groom the mammal's head, ears and eyes. They are generally tolerated by their hosts, and it is assumed that they are searching for ectoparasites. The Terrestrial Brownbul, for example, has been seen to glean ticks off red duikers (*Cephalophus natalensis*). On the other hand, the Yellow-bellied Greenbul has also been recorded as pecking at the preorbital glands of klipspringers (*Oreotragus oreotragus*), where it was possibly seeking to ingest the secretions.

Perhaps the most specialized feeding association among the Pycnonotidae is that shown by Sjöstedt's Greenbul (*Baeopogon clamans*) of west-central Africa. Although the adults of this species also take fruit and other insects, they feed particularly on the immature stages of the small black wasp *Polybioides melaina*, as well as on other hymenopterans. Moreover, the young appear to be fed exclusively on the larvae, pupae and wax of this wasp. It is a striking example of convergent evolution that this pycnonotid species should resemble so closely in appearance the completely unrelated wax-eating honeyguides of the genus *Indicator*.

Breeding

The majority of bulbuls are monogamous. A seemingly unique exception is provided by the Yellow-whiskered Greenbul, which is polygamous and non-territorial, and which apparently adopts a lekking system in part, but only in part, of its range. In Gabon, in areas where the species occurs at high densities, males assemble at traditional sites and sing in chorus. Within these leks, which can be up to 200 m long and 50 wide, each male defends an area of some 20 m in diameter around his songpost, within which he chases off all intruders. The females, which are entirely responsible for raising the young, exhibit a total lack of territoriality, nesting to within 2–3 m and in full view of each other. Studies elsewhere in the Yellow-whiskered Greenbul's range, such as in Kenya and Nigeria, indicate that the species is monogamous and territorial in these regions.

There is also evidence of co-operative breeding for some pycnonotids and it is suspected for others. This strategy may prove to be more common within the family than is currently thought. Evidence is perhaps strongest in the case of the Spotted Greenbul, possibly the most gregarious of all species; fledged young of this greenbul have been seen being fed by four or five members of a group of adults, and observations of the provisioning of nestlings imply the same thing. Likewise, groups of three Short-billed Tetrakas have been observed to feed the same dependent juveniles. Otherwise, the evidence is mostly circumstantial. In the case of the Swamp Palm Greenbul, three or four individuals defended a nest at the approach of an observer, and groups of three adults both of the Yellow-throated Greenbul and of the Seychelles Black Bulbul may jointly defend territories. White-eared Bulbuls in Iraq regularly move around in trios during the breeding season, including the nest-building phase, suggesting that pairs may be accompanied by a helper. Other Asian species suspected of co-operative breeding include the Crested Finchbill (*Spizixos canifrons*), the Straw-headed Bulbul, fledglings of which are sometimes fed by adults other than their parents, and the Yellow-browed Bulbul (*Acritillas indica*), which usually travels in small groups of 6–7 individuals even when feeding young. Similarly, three adults were almost certainly feeding young in one nest of the Puff-throated Bulbul, and several other *Alophoixus* bulbuls are often to be found in groups of 5–8 birds, which seem to be made up of a recent brood accompanied by more than two adults. Co-operative breeding may be the norm in all these cases.

Many pycnonotids breed at varying times of the year and are multi-brooded. Numerous open-country *Pycnonotus* species have been recorded as nesting in all months, and some are known quite commonly to raise three broods in a year, with a maximum of five broods recorded. In equatorial regions, many African species are reported to breed throughout the year, and a good number show a peak of nesting activity associated with short dry seasons; in East Africa, however, there is a tendency for the breeding seasons of both insectivorous and frugivorous species to coincide with the main rains. That generalizations are difficult is illustrated by the Little Greenbul, for which the short dry season in Gabon, in January–February, is the main breeding period, although reproductive activity is recorded in other months; in Itombwe, in DRCongo, on the other hand, this species breeds in all months except the short dry season, there June–August. Among species of montane forest, however, breeding activity tends to be suppressed during the wettest, coldest times of the year.

*The diet of the **Common Tetraka** is highly unusual for a bulbul, which makes sense in view of the fact that it belongs to a Malagasy radiation apparently unrelated to the Pycnonotidae. The extraordinary bill is ideally suited to insectivory, but too long and slender for frugivory; indeed, there is no sign of fruit in the diet at all. Instead, it forages exclusively on insects and small animals, searching for these by clambering up or down trunks or branches, and by peering and probing in dense tangles, dead-leaf clusters, palm fronds and epiphytes, usually 1-20 m above the ground.*

[*Bernieria madagascariensis madagascariensis*, Mt Marojejy, Madagascar. Photo: Roland Seitre]

In southern India, an intensive study of breeding Red-vented and White-browed Bulbuls in Tamil Nadu, in which over 100 nests were found, concluded that the breeding season was annually variable, depending on environmental conditions. Moreover, the two species were not synchronized. In two seasons their peak breeding times overlapped, whereas in another season they nested at slightly different times. No obvious correlation with rainfall could be discerned, although there was a "trend" for breeding to coincide with the start of the wet season. There was, however, a link between the timing of emergence of caterpillars and the breeding of the Red-vented Bulbul. This species feeds its young on caterpillars, and a close correlation was found between peaks in caterpillar abundance and peaks in the bulbul's breeding activity. Nestlings of the White-browed Bulbul appear not to be fed on insects and seem to rely, instead, largely on fruit; there was an indication that the timing of breeding by this species was related to rainfall and fruit production.

It has been shown that good fruiting conditions can prompt some bulbuls to attempt an additional brood. For some species, environmental conditions and the quality of the fruiting season will increase the number of broods produced per annum by one or two. Conversely, a failure of the fruiting season sometimes causes a crash in breeding success. During a long-term study of forest birds in Sarawak, very few fledglings were produced by *Pycnonotus* species in 1966, the explanation for which was a dip in fruit availability caused by environmental factors.

During the breeding season, many bulbuls are very aggressive. Red-vented Bulbuls, in common with many members of the genus *Pycnonotus*, are known to fight for long periods at this time, and this habit has resulted in human exploitation (see Relationship with Man). The Black-headed Bulbul has been noted as repeatedly fighting, with two individuals, the sexes not identified, tumbling to the ground from trees, locked in a fluttering grapple. Male Square-tailed Black Bulbuls also fight fiercely in the breeding season, and defend their nests vigorously against all types of predator.

Courtship behaviour, for those few members of the family for which it has been described, is relatively modest. It is best known for the genus *Pycnonotus*. Thus, Ali and S. D. Ripley state of the Red-whiskered Bulbul that the male postures before his mate, "flattening himself on a perch, lowering his head in a continuous bow, spreading his tail, drooping his open wings loosely at the sides, and gently fluttering or quivering them to the accompaniment of subdued croaks." The male sometimes sings while displaying in this manner; he then hops on to the female's back, and copulation ensues. Other descriptions of this behaviour, for the same species, have pointed out that the male fluffs out his plumage and spreads the vermilion undertail-coverts laterally, to which the female reacts by depressing her crest, lowering the head, wings and tail, and performing curious side-to-side motions with her beak while she utters inane chirps and quivers her wings. White-eared Bulbuls perform a similar display, and it is likely that all of the related *Pycnonotus* bulbuls possessing a brightly coloured vent have a similar crouching behaviour wherein the male spreads and flutters his wings, often above his head, spreads and depresses his tail, and opens out the vent feathering to show off his chief mating signal. Bearing in mind the lack of sexual dimorphism in bulbuls (see Mor-

*The **Slender-billed Greenbul** is an aberrant member of the African genus* Andropadus. *It is generally found in the canopy of evergreen forests, infrequently dropping lower at edges, usually occurring in pairs or small family groups. It sometimes flocks with frugivores at fruiting trees or vines, or associates with mixed-species flocks of insectivores. The diet includes a wide variety of arthropods, including orthopterans, lepidopterans, mantids and arachnids, and this bulbul is occasionally seen flycatching with other species at post-rain emergences of alate termites and ants.*

[*Andropadus gracilirostris percivali*, Mt Kenya, Kenya. Photo: David Fisher]

Most bulbuls drink water regularly, favouring secluded streams, pools and puddles, but taking advantage of artificial supplies of water where available. Several forest-dwelling species are thought to drink regularly in the late afternoon, often combining the activity with bathing. The bulbuls most regularly seen drinking, however, are birds of human settlements and open country, such as the ***Common Bulbul****. In hot climates, these birds seem to need a lot of water, and are found drinking at any time of day, even at dripping taps and leaking pipes.*

[*Pycnonotus barbatus layardi*, Stone Hills Game Sanctuary, Zimbabwe. Photo: J. R. Peek]

phological Aspects), however, it is difficult to identify the sex of the active party, unless copulation ensues. It is thus by no means certain that females never perform these displays, a possibility that will be answered only by intensive study of colour-ringed individuals of known sex.

Similar displays are given by African members of the genus. For example, the male of the African Red-eyed Bulbul performs a characteristic whining wing-flutter display. In this, the body is arched, with the head bent forward and down, the rump and lower back feathers are fluffed up like a puffball, the wings are drooped, with the primaries spread and fluttered gently and continuously, and the tail is spread widely so that the outer rectrices are close to the primaries. Just prior to mating, the spread tail is often bent down vertically. The displaying male sways back and forth, sometimes rotating in a circle, uttering a soft, whining vocalization throughout. The female usually hops closer and around the displaying male, and, in cases where mating takes place, she also often gives this display in close proximity to the male.

Two Asian members of the genus *Pycnonotus*, the Yellow-vented and Flavescent Bulbuls, share a display in which the male and the female perch close to each other. Both sexes then sing, with the wings raised and fluttered over the head.

Pre-copulatory display by the Sombre Greenbul involves the partners facing each other on a horizontal branch, where the male rapidly raises and lowers his head in an elliptical arc, periodically rotates slowly in a complete turn while still head-bobbing, all the time with the feathers of the crown and nape raised, rapidly quivers his slightly opened wings, and utters a soft, keening call with the beak slightly open. The female also bobs her head, out of phase with the male, and utters the same keening call. In the corresponding display by Cabanis's Greenbul, the male intermittently flicks his wings and fans his tail, while erecting his crown feathers and fluffing out those of the throat and rump, and hops in a circle through undergrowth while making a low bubbling call. The female may solicit with shivering wings.

What may possibly be a breeding display has been described for the Black-collared Bulbul. An individual of this species would dart upwards in short jerky flight, with noisy wingbeats, to about 30 m in the air, and remain there for several minutes, before descending rapidly and jerkily. This performance was accompanied by continuous chattering.

There is some evidence of mate-guarding. In Kashmir, for example, the male Himalayan Black Bulbul is said to accompany the female closely during the breeding cycle, suggesting that the male defends his mate against extra-pair copulations. Similar behaviour has been recorded for other pycnonotids. Perhaps surprisingly, courtship feeding has not been reported.

The Common Bulbul is said by van Someren to mate for life in Kenya, whereas Brosset and C. Érard found that pair-members of this species in Gabon may remain together for only a couple of nestings. Rates of mate turnover appear to be greatest where there is considerable and rapid seasonal change in vegetation, as in clearings around villages and in overgrown, abandoned agricultural land, and lowest where the vegetation is less prone to change, such as streamside brush, woodland edge and in gardens.

Most bulbul nests consist of an open cup of leaves and thin pliable plant fibres, built in a tree or shrub. They are usually supported in a fork, but some species, of which the Yellow-browed Bulbul, the Himalayan Black Bulbul and the Tiny and Yellow-Streaked Greenbuls are examples, may sling the nest between twigs. A number of African forest-interior species often incorporate the fungus *Marasmius* into the construction; the black mycelial threads of this fungus grow and ramify through the nest structure, helping to bind it together. The nests of at least two species of *Nicator*, a genus that almost certainly does not belong with the Pycnonotidae (see Systematics), differ considerably, being small, shallow and saucer-shaped. That of the Western Nicator is rudimentary, consisting of a few fibres and rotting twigs laid over a few sticks; the entire structure relies on fungal hyphae growing from the twigs to bind the nest to its support. The White-headed Bulbul (*Cerasophila thompsoni*) also appears to be highly unusual in that it builds its nest in holes in banks. At least five nests of this type have been reported in Myanmar, all 1–2 m above ground level in the sides of cuttings, mostly on a fairly pronounced shelf with a slight recess above it and surrounded by some open vegetation. Another nest of this species, however, was reported to be of the more "normal" sort, an open cup in a low bush, above some cleared ground, but also on a steep bank. Given the unusual nature of these nests, and the lack of formal description included in the paper reporting them, further verification of this nesting strategy is needed.

Some members of the family, such as the Himalayan Black and Square-tailed Black Bulbuls, tend to select nest-sites in isolated trees, often separated from the main forest by a gap of a few metres. This may be a strategy designed to protect the nests against arboreal predators, such as snakes, rats and monkeys. These pycnonotids nest higher up than do most bulbuls, often 5–15 m above the ground, frequently in the canopy, or at the end of long branches; they are therefore probably susceptible to arboreal preda-

tors. The only known nest of the Slender-billed Greenbul, another canopy species, was built in a similar situation.

Nests are sometimes built in odd locations. Both the Yellow-vented Bulbul and the Red-whiskered Bulbul have been recorded as nesting on the ground beneath a bush, and nests of the Red-vented Bulbul have been found in even more exotic sites, such as within buildings, in potted plants on verandahs, in roof thatching and stacks of straw, or even down wells. A nest in Myanmar was made in grass in a vase, and another, in India, was on a chandelier, in each case in a drawing room. The prize, however, goes to the pair of Red-vented Bulbuls that nested repeatedly on the luggage racks of a staff bus in Ahmedabad, in India. The bus was usually parked, but operated twice a day, morning and evening; the female would incubate peacefully while the bus plied its route, but the male generally stayed at the bus station and awaited his family's return. More than one brood was successfully raised in this fashion.

The nesting material used may also be highly variable. Red-vented Bulbuls, and many other *Pycnonotus* species, will often use man-made material, and they vary the make-up of their nests depending on locality and season. In India, nests in Tamil Nadu tended to be made of different plants depending on season, and, of three nests found in an industrial estate in that country, two were structures consisting of about 50% copper wire, a material commonly left lying about in the area. Both White-eyed and Cape Bulbuls sometimes incorporate sheep's wool, feathers, paper, string, newspaper, strips of plastic and other human rubbish into their constructions.

With most species, it is the female that builds the nest, although Ali and Ripley state that both sexes of the Red-whiskered Bulbul share in the task of nest construction. A well-watched colour-ringed population of Red-vented Bulbuls in Fiji allowed a detailed insight into the roles of the sexes in nest-building. Females undertook almost all of the work, the males accompanying them all the while, probably, as mentioned above, for reasons of mate-guarding in the fertile period, rather than assisting. Apparently, the male sometimes brought nesting material back, but this happened only rarely. In the case of the Seychelles Black Bulbul, both members of the pair may share nest-building duties in the early stages, and the presumed female will subsequently complete the construction alone, using material brought by her partner.

Nest-building by Red-vented Bulbuls took 2–5 days, after which there was a pause of 1–2 days before the first egg was laid. Similar figures are reported for other species: 3–8 days for the Yellow-throated Bulbul (*Pycnonotus xantholaemus*), about 6 days for the Flavescent Bulbul in Myanmar, 2–10 days for the Cape Bulbul, with construction taking place mostly during 07:00–11:00 hours, and 6–10 days for the Seychelles Black Bulbul. One pair of Streak-eared Bulbuls took 4 days to build its nest, and the first egg was laid on the fourth day.

In general, bulbul nests are well separated, but in some instances nests are clumped, almost in a loose colony. In Fiji, on two separate occasions, and in Tamil Nadu, India, on one occasion, three active nests of Red-vented Bulbuls were found within a radius of three metres. Similarly, in Tamil Nadu, India, 2–4 nests of the White-browed Bulbul were regularly found within a radius of 8 m. No explanation has been forwarded for this behaviour, but it may be that joint nest defence confers some advantage, especially where predation rates are high.

For the majority of pycnonotids for which relevant data are available, the eggs are generally laid early in the morning at one-day intervals, beginning one to four days after nest completion, and incubation commences when the clutch is complete. There are, however, some exceptions. The laying interval of Red-vented Bulbuls is sometimes two days and in some species intermittent incubation may begin with the first or second egg, resulting in a disparity in hatching dates and in the sizes of nestlings.

In many African species, the clutch usually consists of two eggs and sometimes of three, although *Pycnonotus* species not uncommonly lay four or five eggs, while the clutches of Western Nicators are always of just one. Some regional variation in clutch size occurs among Red-vented Bulbuls. In Sri Lanka, for example, pairs in the highlands tend to lay three eggs, whereas those in the lowlands tend to lay two. Similarly, Red-vented Bulbuls in the Himalayas lay larger clutches than do those from the hotter lowlands of southern India. There is much variation in egg colour, both within and among species, and many eggs are distinctively, and often attractively, marked. The ground colour is usually pale, often whitish, cream or pinkish, and overlaid with darker spotting or scrawling which is frequently concentrated as a ring around the larger end, sometimes forming a cap.

Incubation is usually undertaken by the female alone, and for most species lasts 11–14 days. The males of some species, however, occasionally incubate for short periods, usually no more than a few minutes, although the male Seychelles Black Bulbul may incubate for up to one hour per day. Hatching is normally

There are a few reports of bulbul nests built by both sexes, but in most well-studied cases the female does all the work, either alone or closely accompanied by the male. In general, male birds following nest-building females are not offering practical or moral support, they are simply making sure that their partners do not mate with rival males during the fertile period. In all likelihood, therefore, this is a female ***Himalayan Bulbul****, and the task of nest construction will take her anything between 2 and 10 days. She will lay the first egg 1–10 days after the nest is finally completed.*

Breeding information is scant for the five Malagasy tetrakas. From the few data gathered it appears that their nests are unusual, which makes sense in view of the recent findings that they are not related to bulbuls. This ***Short-billed Tetraka*** *has built a beautiful pouch of slender stems and moss, slinging the structure hammock-style between the branches of an understorey shrub, not far above ground level. The outer layer is adorned with dead leaves, a technique that no doubt helps camouflage the structure. It is neater than most bulbul nests, most of which are supported beneath the cup rather than attached at the rim.*

[*Xanthomixis zosterops*, Madagascar. Photo: Dominique Halleux/Bios]

synchronous, but in some cases, including the White-browed and Red-vented Bulbuls, it may be asynchronous (in one extreme case the two eggs of a clutch hatched a week apart).

Bulbul chicks are nidicolous, helpless and blind for the first few days. Observations on post-hatching development at one closely watched nest of a pair of Streak-eared Bulbuls in Malaysia are typical. On the first day after hatching, the single chick weighed 3·4 g, this rising steadily to 10·3 g by the fifth day, by which time its eyes were still closed; on the following day, its weight had risen to 13·2 g and the eyes were fractionally open. By the seventh day, the nestling's eyes were fully open, all feathers were in pin, and the wing and contour feathers were just out of pin; by the tenth day, the tail feathers were out of pin and the chick weighed 20·1 g. The youngster fledged twelve days after hatching. As this chick was alone in the nest, it probably developed slightly faster than would chicks in broods of two or more. Of interest, incidentally, is E. C. Stuart Baker's statement that nestlings of White-throated Bulbuls in north-east India are not molested by leeches, no matter how numerous the latter are. Given that leeches can be a scourge of defenceless nestling birds, this raises the possibility that the bulbul chicks have developed some defence, perhaps biochemical, against these blood-sucking annelids.

The nestlings of some pycnonotids, such as the Red-vented, Red-whiskered and Cape Bulbuls, tend to be fed initially with more soft-bodied insects and larvae than are present in the adult diet, presumably as a means of providing sufficient calcium and protein to meet their growth requirements. Similarly, Yellow-whiskered Greenbul chicks are fed only with insects for their first four days, then with a mixture of fruit and insects and, during the last week in the nest, with fruit alone; studies have shown that they are fed, on average, every 40 minutes. The young of Sjöstedt's Greenbul are provisioned exclusively with wax, larvae and pupae of the wasp *Polybioides melaina*, an important source of food for the adults of this species (see Food and Feeding). A particularly unusual observation concerned an adult Red-vented Bulbul that delivered a young 9-cm lizard (*Calotes versicolor*) to a chick 5–6 days old and of roughly the same size as the reptile; this oversized food item eventually caused the death of the nesting, which had attempted to swallow it.

In most, if not all, pycnonotids, the female does the majority of the brooding but both sexes contribute to provisioning. Yellow-whiskered Greenbul chicks are brooded closely by the female for the first week, and thereafter at intervals, until they are almost feathered; the males may feed the chicks directly or may pass food first to the female, she then feeding the brood. Chicks of the Yellow-bellied Greenbul are brooded closely for the first two days after hatching, during which time the female is fed at the nest by her mate. It was found that, on day three, the male fed the chicks and then brooded them while the female went off to find food; she returned and fed the brood, after which both parents left the nest for a while. Both Common and Red-vented Bulbuls have been noted to remove faecal sacs carefully from the nest, sometimes swallowing them, up to the time when the young fledge, such that the nest and the ground below it remain completely clean. This behaviour is also recorded for the Cape Bulbul: the nestlings' faeces were swallowed by the parents until the eighth day, after which sacs were removed and dropped 5–20 m from nest.

The fledging period is in the range 12–16 days for most species for which data are known, although it is shorter, only 9–11 days, for the White-browed and White-eared Bulbuls and 21 days in the case of the larger Seychelles Black Bulbul. In Kenya, van Someren reported that 16-day-old nestlings of a pair of Yellow-bellied Greenbuls were able to stand up, stretch and preen. Their parents then induced them to leave the nest by holding berries in the bill while calling to the chicks from a branch 0·5 m away; the young at first remained in the nest and answered the parents' call, but then they hopped and flapped out and on to the branch. On subsequent feeds, the young were tempted farther from the nest. The single chick of the Western Nicator leaves its nest after 16–18 days, well before it is able to fly, because by this stage the nestling is too big for it. The chick moves about on branches with agility, watched over by one parent; in situations of danger, the parent gives the alarm and the youngster remains motionless among leaves, well camouflaged by it spotted appearance.

Young Yellow-vented Bulbuls make their first independent captures of insects from the fourth day after fledging, but they continue to be tended by the parents for a few weeks. In captivity, the parents made feeding visits to their offspring for approximately one month after the latter fledged. The young of Seychelles Black Bulbuls are reportedly fed by the adults for one week after fledging, although other observations indicate that begging juveniles are ignored or chased off. Cape Bulbul fledglings, in con-

The classic bulbul nests are built by familiar members of the genus Pycnonotus, *such as the* ***Cape Bulbul****. These nests are bulky, sturdy and often poorly concealed. They usually consist of a foundation of coarse twigs, resting in an upright fork, or otherwise supported underneath by branches. The open cup is built atop this foundation, again from fairly coarse material such as twigs, stems, grasses and rootlets. The interior surface is lined with finer plant fibres, and whatever soft material is available in the vicinity: sheep's wool, cobwebs, feathers, paper, string and other human rubbish. In most bulbuls only the female incubates.*

[*Pycnonotus capensis*, southern Karoo, near Ladismith, South Africa. Photo: Warwick Tarboton]

trast, are fed for at least two weeks and occasionally for a month; they are fully independent by 40–50 days after leaving the nest.

During long-term mist-netting studies in both Singapore and Sarawak, most young bulbuls were not trapped until at least 4–6 weeks after fledging. This is presumably because they receive much food from their parents before that time, and consequently fly around very little. As with many forest birds, bulbuls tend to have a prolonged period of parental care. In Fogden's study in Sarawak, it was found that adults of the forest-dwelling Puff-backed, Grey-cheeked and Yellow-bellied Bulbuls fed their offspring for at least ten weeks. This reduces their ability to have second or third broods, something which is often achieved by open-country bulbuls, and is probably associated with a general scarcity of resources, or a specialism in foraging techniques that requires young birds to gain experience over a longer period of time. In this instance, the three bulbuls with the longest period of parental care, those mentioned above, were also the most insectivorous during the post-fledging period. Conversely, members of the genus *Pycnonotus* that were chiefly frugivorous, such as the Olive-winged Bulbul, had much shorter periods of parental care, presumably because the practice of foraging on fruit in the rainforest is much easier, especially when the fruiting season is a good one.

On the approach of a predator, adults of several Asian *Pycnonotus* species, including the Himalayan, Red-whiskered, Yellow-vented and White-eared Bulbuls, defend their nests or fledglings by conspicuous distraction displays. They feign injury and flutter to the ground as if unable to fly; if approached closely, they fly back up to a safe perch. Individuals have been seen to lead crows and dogs away from recently fledged chicks in this manner. In the case of the Himalayan Bulbul, at least, both adults feign injury, demonstrating that males have a high level of investment in parental care. Ali and Ripley state that Red-whiskered Bulbuls, when their nests are threatened, drag themselves along the ground with outspread beating wings, screaming piteously.

Such displays are reported for several African species, too. The female Yellow-whiskered Greenbul, for example, drops to the ground, lies there while fluttering, and then crawls off with drooping wings and spread tail; she may sometimes run off noisily, like a rodent, upon hitting the forest floor. On one occasion, van Someren followed a female which fluttered along the ground for 15 m, flew into bushes, and then continued for a further 10 m, before disappearing; when the observer returned to the nest, the hen was already back on it. On another occasion, the greenbul gave a distraction display for a distance of 20 m while the observer, instead of following her, remained at the nest; when she saw that her display was not working, she flew back and resumed incubating, even though the observer was still standing by the nest. Similar behaviour has been reported for members of the genera *Cholorocichla*, *Phyllastrephus* and *Nicator*. Not all bulbuls perform distraction displays, however: in a study of Red-vented Bulbul and White-browed Bulbul in Tamil Nadu, India, the former regularly feigned injury whereas the latter never did.

What data there are on breeding success of pycnonotids indicate that it is generally low. For example, V. S. Vijayan noted

The ***White-browed Bulbul*** *is a common breeding bird in Sri Lanka and south India, where nests have been found in all months, with little sign of strict seasonality. Pairs raise, or at least attempt to raise, several broods a year. Its nest is smaller than those of true* Pycnonotus *bulbuls, an unlined, flimsy structure which, according to one study in Tamil Nadu, India, is preferentially sited in thorny bushes. The same probably applies to Sri Lanka, as this photo testifies. The clutch typically contains two eggs, which are usually incubated by the female for 11 days; the nestlings fledge some 10 days later.*

[*Pycnonotus luteolus insulae*, Sri Lanka. Photo: T. S. Zylva/FLPA]

that, of 134 eggs laid by Red-vented Bulbuls during a 16-month period at Point Calimere, in south India, as few as eleven, or 8·3%, survived to produce fledglings. Similarly, of 114 eggs laid by White-browed Bulbuls at the same site, only 15, 13·2%, produced fledglings. Chicks died in the nest from what appeared to be starvation, or eggs were infertile, or predators took their toll.

In Africa, Brosset and Érard found that 27 of 38 nests of Icterine Greenbuls in Gabon were destroyed by predators; further, in the eleven nests which did produce flying young, one egg was infertile in four cases, one young disappeared in three cases, and in eight instances only a single young fledged. Also in Gabon, where the Yellow-whiskered Greenbul, as mentioned at the beginning of this section, breeds polygamously, using a lek system, this species' breeding success varies widely with predation levels; 45–85% of nests were preyed on annually, with a mean of 75%. A complete cessation of breeding by Yellow-whiskered Greenbuls was observed in two successive years, even though environmental conditions remained unchanged and other bird species bred normally. This reaction was thought to be probably an anti-predator strategy, because, in the year in which breeding resumed, predation of nests fell to 46% and the local population of Yellow-whiskered Greenbuls jumped by 50%, with 2·43 young fledged per nest. In the following four years, nest predation increased to 78%, while the number of fledglings fell to 1·95 per nest. In a study of Cape Bulbuls in South Africa, 233 eggs laid produced 63 fledglings, a success rate of only 27%. The survival rate of fledglings was estimated to be 18% after one month and 10% after one year.

The design of bulbul nests leaves them vulnerable to brood parasites. In Asia, the only species reported to be affected are the Red-vented and Flavescent Bulbuls, both parasitized by the Jacobin Cuckoo (*Clamator jacobinus*), but it is likely that several more pycnonotids in the region are cuckoo hosts. This is certainly true if one judges on the basis of information from Africa, where the Jacobin Cuckoo is known to affect Common, African Red-eyed and Cape Bulbuls and Sombre Greenbuls. In addition, the Yellow-whiskered Greenbul and the Common Bulbul are hosts of the African Emerald Cuckoo (*Chrysococcyx cupreus*), the Yellow-throated Greenbul and the Common Bulbul are hosts of the Red-chested Cuckoo (*Cuculus solitarius*), while the Common Bulbul is further parasitized by both Klaas's (*Chrysococcyx klaas*) and Diederik Cuckoos (*Chrysococcyx caprius*). In a four-year study in one area, levels of parasitism of Cape Bulbuls by Jacobin Cuckoos varied between 12% and 73%, the mean being 39%. Since many parasitized nests were preyed upon, however, losses to cuckoos amounted to only 7%.

Rates of predation suffered by many common pycnonotids seem to be high. R. M. Betham noted that clutches of White-eared Bulbuls in Pakistan were usually preyed on shortly after laying. According to him, the "remark that the bulbul performs the function of the domestic fowl to crows and such like by providing the egg for the breakfast table" seems to be a very apt one. He noted, as have many others, that bulbul nests are easy to find, as the adults are not particularly circumspect around the nest. Perhaps this goes some way towards explaining the high levels of predation reported for some species. Ali and Ripley wrote that the eggs and nestlings of the Red-whiskered Bulbul suffer very heavy predation, principally by cats, crows, koels (*Eudynamys*) and *Calotes* lizards. Predation of Red-vented Bulbul eggs and nestlings in Pakistan by crows and *Calotes* lizards is common, and one nestling was consumed by a saw-scaled viper (*Echis carinatus*). In south India, the survival rate of Red-vented Bulbul offspring is only 13%; the figure drops to 8% in the introduced population in Fiji, presumably a result of higher rates of predation. It is interesting to note that such low breeding success has not affected this species' ability to colonize Fiji, where it has become widespread and abundant in less than 80 years.

In Gabon, of a total of 35 nests of Eastern Bearded Greenbuls, as many as 26, or 74%, were destroyed by predators, including in two cases by mandrills (*Papio mandrillus*), as were 82% of 64 nests of Lesser Bristlebills. Losses to predation of Common Bulbul nests were somewhat lower, amounting to 42% of 64 nests, all destroyed by driver ants. Predation rates in a study of Cape Bulbuls were 60–83%. Of these losses, 70% were due to mammals, particularly rodents such as the vlei rat (*Otomys irroratus*), the forest dormouse (*Clavigulus murinus*) and the four-striped grass mouse (*Rhabdomys pumilio*), but also vervet monkeys (*Cercopithecus aethiops*), mongooses (Herpestinae) and felids; birds, primarily White-browed Coucals (*Centropus superciliosus*) and Southern Boubous (*Laniarius ferrugineus*), were responsible for 16%, and snakes, mainly *Dasypeltis scabra*, for the remainder.

Bulbul chicks are nidicolous, by which it is meant that they are blind, naked and helpless during the first few days after hatching. They rapidly develop pin feathers from feather tracts, with the tips of wing and contour feathers emerging from pin by the seventh day after hatching, by which time the eyes are fully open. The nest of this ***Cream-vented Bulbul*** *is a bulky structure of twigs and creeper tendrils (and what seem to be horsehair fungal hyphae). It contains a brood of two, which is typical for tropical members of the family. The size of broods rises to 4, or at most 5, in species that nest at much higher latitudes or altitudes.*

[*Pycnonotus simplex simplex*, Panti Forest Reserve, Malaysia. Photo: Jimmy Chew]

From what is known about provisioning in bulbuls it would appear that adults, regardless of the extent of their own frugivory, tend to feed their nestlings mainly with soft-bodied insects. While this seems to be especially true in the first few days after hatching, the proportion of fruit in the diet increases steadily as the fledging date approaches. In general, therefore, the diet of bulbuls contains more invertebrate food when the birds are nest-bound than at any other stage of life. This tendency relates to the calcium and protein requirement of chicks: a young ***Olive-winged Bulbul*** *fed exclusively on fruit probably takes much longer to fledge, greatly increasing the risk of predation.*

[*Pycnonotus plumosus plumosus*, Singapore.

Movements

Pycnonotids are, for the most part, sedentary birds. Some species, however, in at least parts of their range, may be locally nomadic. This is thought to be a response by some frugivorous species to the fluctuating availability of food supplies. The Black-and-white Bulbul is perhaps the most pronounced nomad, large influxes of this species having been recorded in, for example, the river-terrace forest of the Endau–Rompin conservation area in Peninsular Malaysia, coinciding with extensive synchronous fruiting events. D. R. Wells writes that such gatherings occur to no obvious seasonal schedule; small to large numbers invade a presumed temporarily attractive locality quite abruptly, remain for a few weeks to a few months, and then disappear as suddenly as they came, not to be seen again for periods of months up to as long as one year. The Black-and-white Bulbul is unusual in that it appears to disdain all figs, a widely available food source which other forest-dwelling *Pycnonotus* bulbuls in the region exploit in between flushes of other kinds of fruit.

Elsewhere, other members of this genus are nomadic in parts of their range in the non-breeding season. Thus, the Common Bulbul is reported as wandering locally in north Africa during the northern winter, while populations of the same species vacate the most arid parts of their Sahelian range, in Senegal at least, at the height of the dry season. Towards the southern end of the continent, during the austral winter, the African Red-eyed Bulbul undertakes movements, sometimes in large numbers, into marginal areas of its range, including shifts of up to 200 km northeast of its breeding distribution in northern Botswana. This species also makes regular but temporary influxes into parts of the arid central Karoo, these coinciding with periods of high rainfall or with fruiting seasons of trees and shrubs.

Large non-breeding aggregations of Yellow-vented Bulbuls roost communally in Malaysian reedbeds. Regular-effort mist-netting conducted during the 1960s at two roosts in Selangor recaptured only 7% of 1437 individuals ringed over three consecutive years at a *Phragmites* reedbed site. This poor return suggests either that these roosts attracted a sustained throughput of dispersing bulbuls which did not return regularly, or that many nomadic non-breeding individuals make opportunistic use of a succession of such roosts.

Some forest-interior pycnonotids also appear to be nomadic. Several long-term mist-netting studies in Malaysia have demonstrated that retraps of many bulbul species are rather few, because, it is thought, many frugivorous species are non-territorial and are constantly on the roam in search of transient food sources. This is in contrast to *Alophoixus* species, which are regularly retrapped, often in the same net-lines, suggesting that these insectivores defend territories throughout the year. These findings are mirrored by similar studies in Africa, where, in Gabon for example, very few ringed Little and Yellow-whiskered Greenbuls were ever retrapped, whereas the rates of recapture for some of the more narrowly insectivorous species, such as those in the genera *Phyllastrephus* and *Bleda*, were much higher. Elsewhere in Africa, however, the Yellow-whiskered Greenbul, at least, appears less inclined to wander; the population in Ogba, in Nigeria, was thought to be sedentary.

Altitudinal migration has been observed for a number of species. A good example is that of the Himalayan Black Bulbul, which is often resident regionally in the Himalayas, but moves downslope in the cold season. In Himachal Pradesh, it is found between 1220 m and 2130 m in winter, shifting upslope to 1830–3050 m in the summer, when it breeds. Other common species in the region, such as the Red-vented and Himalayan Bulbuls, do not exhibit such behaviour. At the opposite end of India, in the southern part of the Western Ghats, another *Hypsipetes*, the Square-tailed Black Bulbul, has also been noted as making seasonal altitudinal movements, breeding at high elevations and then, in July–December, moving to lower levels. This species vacates many areas in the southern Western Ghats, such as the Silent Valley, during the peak of the monsoon season, unlike the Yellow-browed Bulbul, which is permanently resident regardless of the strength of the monsoon. It has been suggested that the higher levels of frugivory and generalism in the diet of the latter allows it to be sedentary, while the more insectivorous *Hypsipetes* is forced to look elsewhere for its food supply.

A number of African members of the family also undertake altitudinal migrations. For example, all five montane species of *Andropadus* are known to move, or suspected of moving, to lower levels during the non-breeding season in at least parts of their ranges. These movements generally coincide with the cold, dry season, and are probably related to food shortages at higher el-

Rather a large proportion of bulbuls are group-living, and in several of these cases breeding appears to be co-operative. Given that the ***Yellow-streaked Greenbul*** *often consorts in small groups of 5–6 individuals, we might expect to find communal provisioning or helpers at the nest in this species, but the available evidence suggests that it is monogamous, and that groups disband into pairs for breeding. Most true co-operative breeders form monospecific flocks, but this taxon very often associates with mixed-species aggregations of insectivores. Like them it is almost wholly insectivorous when adult, catching grasshoppers, beetles, bugs, caterpillars, spiders and small gastropods, supplemented with only a small amount of fruit. Unsurprisingly, most food items brought to the nest are insects too, and these are stuffed deeply into the gape of nestlings. In most young bulbuls the gape is brightly coloured, usually red and often uniform, but occasionally with some patterning. Of interest, therefore, is the fact that nestlings in this species have bright yellow gapes, according to this photograph. Either way, if bulbuls are at all similar to most passerine birds, the saturation of pigment in the mouths of nestlings is related to blood supply, which itself is linked to digestion, providing a system whereby the visiting adult can assess the relative hunger of the chicks.*

[*Phyllastrephus flavostriatus flavostriatus*, Mutate area, Zimbabwe. Photos: Geoff McIlleron]

*The **Red-whiskered Bulbul**, in common with several congeners, is often found nesting in odd situations. Natural sites tend to be in shrubs, creepers or trees, including dense-foliaged exotic conifers, as well as bamboo and mangroves. But in towns and villages it often places its nest in man-made situations, including in trellises, baskets, roof thatching, stacks of straw, in pot-plants standing on verandahs, and even down wells. Like most bulbuls with largely frugivorous diets, the adults feed the nestlings copious amounts of fruit when fledging draws near. At this stage parental visits to the nest are very frequent, and fruit, being much easier to locate and collect than insects, provides an important supply of food. Partly because bulbul nests are large and poorly concealed, and partly because adult birds are not particularly circumspect in their vicinity, they seem to suffer inordinately high predation rates. In most studies of pycnonotids the number of eggs producing fledglings is around 10%. Eggs and chicks are usually taken by birds such as corvids, as well as lizards, snakes and monkeys.*

[*Pycnonotus jocosus*. Photo: Vivek Sinha/SAL/ Oxford Scientific Films]

At most bulbul nests, including those of the ***Sombre Greenbul****, both parents feed the nestlings. The task of brooding chicks in this species seems to vary, however, with females taking the responsibility at some nests, but males sharing this duty at others. The length of the fledging period is highly variable too, with some broods fledging 10·5 days after hatching, and others remaining in the nest for 16 days. In one study an average of 1·73 chicks fledged per successful nest.*

[*Andropadus importunus importunus*, Kirstenbosch, Cape Town, South Africa. Photo: David Steele/ Photo Access]

evations over this period. There is a record of the Eastern Mountain Greenbul from the edge of Lake Malawi, over 30 km from the nearest montane forest, and, even more remarkably, a Stripe-cheeked Greenbul was caught in a mist-net in the Pugu Hills of coastal Tanzania, over 200 km from the species' nearest known breeding population. Although such records are undoubtedly exceptional, results from ringing studies do indicate that these species will move between forest patches several kilometres apart. Yellow-streaked Greenbuls, in the genus *Phyllastrephus*, undertake similar movements between forest patches in Malawi, while the Reunion Black Bulbul perfoms a seasonal altitudinal migration, moving to lower elevations during the non-breeding season, possibly in response to decreased food supply in upland indigenous forests during the austral winter.

Several subspecies of the Himalayan Black Bulbul are fully migratory, and there is a huge passage through parts of South-east Asia of individuals moving from breeding grounds in China to spend the northern winter in Myanmar and Indochina. The passage through Hong Kong is interesting in its timing. The vast majority of sightings occur between early February and mid-April but few migrants are seen in autumn, suggesting that different routes are used in the two seasons. During this spring period, the passage is irregular and depends upon weather conditions, with big influxes on some days and none on others. The tendency for long-distance migrations and vagrancy within *Hypsipetes* explains the colonization of remote oceanic islands by members of this group.

With regard to the issue of vagrancy, a degree of caution is required. This is because many pycnonotids are widely held in captivity (see Relationship with Man), a fact which causes repeated problems for ornithologists when assessing records of potential vagrants. Red-whiskered Bulbuls at Beijing, in east China, Black-capped Bulbuls in Singapore and Sooty-headed Bulbuls (*Pycnonotus aurigaster*) in north Sulawesi are just three examples of what are believed to have been escapees from captivity.

Relationship with Man

Bulbuls, at least those in the genera *Pycnonotus* and *Alophoixus*, receive for the most part a remarkably consistent press across their ranges. The same adjectives crop up repeatedly; they are described as jaunty, vivacious, cheerful, cheeky, sprightly, lively, brash, self-confident, bold, frolicsome, and cheery. This is due to their ubiquity and familiarity across rural, suburban and urban environments, their confiding, energetic and pugnacious behaviour, and their persistent, penetrating vocalizations. Nevertheless, their voices can become wearing: according to E. S. Wilkinson, the song of the bulbul is "monotonous through lack of variety… acquiring merit only by its spontaneous cheerfulness", while Moreau found that, although the song varied somewhat by locality, "the same bird is liable to indulge in wearisome iteration". On the other hand, V. Legge stated that the Red-vented Bulbul in Sri Lanka was a universal favourite among Europeans, many of whom rated its singing so highly that they referred to it as the "Ceylon Nightingale".

Two further quotations round out the picture. Thus, of the Himalayan Bulbul in Kashmir, H. Whistler wrote: "with its bright cheeky behaviour, quaintly cocked crest, and pleasant notes, it is a universal favourite, catching the eye even of the most unobservant, as it enters boats and houses, or hops about the feet of picnic parties in search of stray scraps and greedily eating bread and cake thrown to it." With equal enthusiasm, G. L. Bates summed up the Common Bulbul in West Africa as follows: "its great success in life—for it is absolutely the commonest good-sized, non-gregarious bird—is due to brains and adaptability. The notion of its intelligence given by its twinkling black eye is not fanciful, but is supported by a serious study of its ways and methods, which are more various than those of most birds; one mark of intelligence is its confidence in man." Although one may demur as to whether confidence in man is really a sound measure of intelligence, the point is made that these birds are well known and, for the most part, admired across much of Africa and Asia.

This appears not to be a new phenomenon. Pycnonotids are such a familiar part of the Asian environment that the word "bulbul" is mentioned widely in Asian, and particularly Persian, poetry. In this context, a caged bulbul may be used to serve as a metaphor for being held captive or for conscience. The term "bulbul" is also often applied directly to poets and singers in Iran and elsewhere. There is, however, some confusion as to which bird is actually meant, since the word "bulbul" is often

*In the **Yellow-vented Bulbul**, fledglings can feed independently four days after leaving the nest, but they are usually fed by adults, at least occasionally, for up to a month. Most bulbuls are fully independent 40–50 days after leaving the nest, by which time they are often chased off the natal territory by the adults. The period of post-fledging care tends to be longer in insectivorous forest-dwelling bulbuls. Young of these species are often fed for up to 10 weeks by adults, probably because of the general scarcity of invertebrate food and the longer training period necessary to acquire the appropriate foraging skills.*

[*Pycnonotus goiavier analis*, Singapore. Photo: Morten Strange]

translated as "nightingale" and may, therefore, not relate to Pycnonotidae. What is certain is the use of illustrations of Brown-eared Bulbuls in Japanese fine arts, such as colour woodblock prints and fan paintings.

The cagebird trade in Asia is a serious issue, and one which may be driving a few species, such as the Straw-headed Bulbul, towards extinction (see Status and Conservation). In Vietnam, Red-whiskered, Black-capped, Sooty-headed and Streak-eared Bulbuls have recently been found in trade in fairly large numbers in Ho Chi Minh City and Hanoi. The numbers seen there, however, were far outweighed by the 6889 Red-whiskered Bulbuls counted in the late 1980s at the Bangkok weekend market, where this species represented 10% of the total birds and was the second most commonly encountered species.

Among birds seen in the Calcutta market, in India, the Red-vented Bulbul was by far the most common, perhaps because of the tradition of bulbul-fighting. With reference to this species, F. Finn stated: "it is not so often caged, however, as tethered to an iron T-shaped perch padded with cloth, the cord being fastened to a soft string round its body. This is to further its employment as a fighting bird, that being the purpose for which it is commonly kept. Two individuals are made hungry, and then their jealousy is excited by offering food to one only, which of course provokes a fight." Thus induced into battle, the Red-vented Bulbuls flapped at each other and pulled out feathers in rather dramatic fashion, while bets were placed on which bird would be the "winner". According to Finn, the sport was popular in winter, after which the birds were released, "with the exception of such as have proved worthy of maintenance for the future".

It seems that this practice was widespread in India, and probably also in neighbouring Bangladesh. In the 1880s, G. Reid wrote that, in Lucknow, the species "is prized by the natives for its fighting qualities" and "trained for the same purpose"; he added that he had seen in the courtyards of country magnates as many as a hundred perched on, and fastened to, separate sticks shaped like the letter "T". Ali and Ripley, referring to the same species give the following account:

> "Before the law prohibiting animal fights came into force, these bulbuls were trained for fighting in some provinces. They were fed a special diet to produce extra courage and pugnacity. The two adversaries were placed facing each other on T-shaped perches, at a distance calculated to allow the most powerful blows. The birds were tethered by a cord fastened to a soft string round the body [*pēti*, or 'braces'], 'this fact transforming the fight to a duel "to the finish". In the meantime spectators placed heavy bets'... Notwithstanding the ban, bulbul fighting still continues as a popular rural sport at fairs and on high days and holidays in some parts of the country. Considerable sums change hands over the mains, and champion birds fetch high prices."

Apparently, this was the only species in the sprawling Calcutta market utilized in such a way, although several other pycnonotids offered for sale included the Red-whiskered and Black-crested Bulbuls, irregular but sometimes considerable numbers of White-eared and Himalayan Bulbuls, and also, from farther afield, the Light-vented Bulbul. In addition, Ashy Bulbuls, Mountain Bulbuls (*Ixos mcclellandii*) and Himalayan Black Bulbuls were sometimes brought to Calcutta during the winter. The fact that this information derives from 1902 reveals the extent to which bulbul-trafficking over considerable distances has been an important factor for more than a century. Moreover, the trade was not restricted to India. In Pakistani bazaars, captured Himalayan Bulbuls or associated hybrids were tied to perches and sold. They were caught in traps baited with white ants, which they were said to be "unable to resist". In Sri Lanka, Red-vented Bulbuls are still a favourite pet, in part because they are so easily habituated to people. They are usually kept caged, but become so tame that they allow themselves to be carried around perched on a shoulder or hand.

The commercial use of bulbuls has taken a different turn in South-east Asia. In south Thailand, at least, the popularity of pitting caged bulbuls against each other in song-contests has taken off in recent years. Again, a lot of money changes hands, as the betting fraternity has become heavily involved and demand appears to be large. This has implications for conservation, as the Red-whiskered Bulbul, the favourite species, has now disappeared from much of Thailand, where it was formerly very common, through a combination of trapping for the cagebird trade and trapping for song-contests (see Status and Conservation). The situation is exacerbated by the fact that this bulbul is difficult to breed

in captivity, and wild individuals are preferred over captive-bred ones as they are believed to have a richer song.

Finally, throughout South-east Asia, bulbuls are often sold as religious gifts: caged individuals are among the birds most frequently released during Buddhist festivals, or as symbolic offerings by pilgrims at shrines and temples. Although these birds are not permanently removed from the wild, they are often translocated from their natural range. As a result, this tradition causes repeated problems in the assessment of records of potential vagrants (see Movements) and can result in changes in distribution (see Status and Conservation). In extreme cases, extralimital populations sometimes become established around major Buddhist shrines where the release of cagebirds is a regular event; in Malaysia, for example, a population of Red-whiskered Bulbuls has become established around the Kek Lock Tong caves, in Perak.

In contrast to the situation in Asia, the cagebird trade in bulbuls in Africa and the western Indian Ocean islands is virtually non-existent and, with one exception, it is certainly not thought to be on a scale large enough to pose a threat to any species. The exception is that of the Reunion Black Bulbul, which, although once considered "extraordinarily abundant", is now uncommon, largely as a result of hunting. Although hunting, formerly legal, is now prohibited, and this species' numbers are thought to be increasing in consequence, the biggest constraint to its recovery is the illegal capture of birds for the local cagebird trade, where its abilities as a songster are much appreciated.

In the early nineteenth century, the Reunion Black Bulbul was so numerous that it could be relied upon to provide an expedition to remoter parts of the island with its meat ration, since it was "so abundant, tame and inquisitive that a few minutes work with a baton would easily supply the day's need". Hunting of Reunion Black and Mauritius Black Bulbuls, much appreciated for their culinary value, was a long-standing tradition on both islands, but it is now illegal, although only since 1989 on Reunion. Both species have suffered catastrophic declines in historical times, a result primarily of a combination of hunting and habitat destruction (see Status and Conservation).

Across Asia, bulbuls are trapped or killed for food using a variety of ingenious techniques. In the Philippines, they continue to be caught in light-traps set at night to lure migrant birds at Dalton Pass, Luzon. Yellow-vented Bulbuls and Philippine Bulbuls (*Ixos philippinus*) are taken, along with other birds, which are then sold on to food markets. Bulbuls are also caught for food in parts of India, including Assam, where hunters use a *Forâla*, a glue-tipped pole baited with a live termite, to catch Red-vented Bulbuls, among many other passerines. Hunting of Black-crested Bulbuls around Yangon, Myanmar, was noted in the late 19th century to involve firing mud bullets from a bamboo bow. In Laos, too, pycnonotids are a prize target; Mountain Bulbuls, for example, are mostly quite tame and easily killed in remote regions, where they tend not to fly away when shot at. Bundles of bulbuls, mixed in with other passerines and tied together with string or strips of bamboo bark through their nostrils, end up in little piles at open-air markets.

One group of people to whom bulbuls do not endear themselves are orchard-owners and other farmers. In Japan, for instance, Brown-eared Bulbuls are considered to come second only to crows in the amount of crop damage that they cause, particularly to citrus fruits, especially oranges, but also, more recently, to various kinds of leaf vegetables during the winter. This novel food source for this species appears to have prompted a change in behaviour by at least part of the population; since the 1970s, rather than migrating to the southern part of Japan, Brown-eared Bulbuls have started to remain on their northern breeding grounds during the winter, at the expense of winter cabbage and other leaf vegetables. A further instance of exploitation of a new food source in that country is provided by the Light-vented Bulbul, which first appeared in Okinawa in the 1970s and began to eat the leaves and fruit of vegetables. It has increased in numbers and is now considered a major threat to crop productivity. In China, this species causes a great deal of damage to strawberries and tomatoes in suburban gardens.

Other examples of bulbuls as crop pests include the Red-whiskered Bulbul, which can cause serious damage to buds and ripening fruit in Indian orchards and which takes flower buds and seedlings from gardens. It also loves *Lantana* fruit, and in north Thailand is implicated in the dramatic and damaging spread of this introduced weed. Likewise, the Red-vented Bulbul is known to damage fruit, flowers and peas. In Pakistan, it is a serious pest in fruit orchards, in particular of persimmons (*Diospyros kaki*) and guava (*Psidium guajava*), and it also causes damage in citrus orchards, both orange and grapefruit, after parakeets have initiated the process by piercing the skin of the fruit. This species is implicated in spreading *Lantana* around Sri Lanka in the 1800s. In India, it is "very destructive to peas, strawberries, brazil-cherries (*Physalis peruviana*), and other soft fruit". Himalayan Bulbuls have been known to devastate crops of peas, currants, raspberries and other domestic foods in Kashmir, while Yellow-vented Bulbuls are reported as doing a "good deal of damage" to pepper crops in Borneo.

The White-eyed Bulbul is another species which has adapted well to novel food sources. Indeed, it has, since the 1930s, been able to expand its range significantly in some areas as a consequence of the spread of human settlements and the cultivation of fruit crops into desert areas. It is regarded as an agricultural pest in some places, and may be killed legally in Israel. The Common Bulbul exhibited a similar range expansion during the twentieth century in Egypt, where it is sometimes killed as a pest in fruit orchards.

Nevertheless, the culpability of pycnonotids as crop pests needs to be balanced against their beneficial effects in gardens and cultivated land. Although these are less well understood and documented, bulbuls are also active pollinators and seed-disseminators, as well as playing a role in controlling populations of more damaging agricultural pests, such as caterpillars.

*The **Grey-bellied Bulbul**, one of the more attractive members of the family, is restricted to humid forests in the Malay Peninsula and the islands of Sumatra and Borneo. It is not a rare bird, but the scale of habitat destruction in the Sundaic lowlands over the last few decades means that its population must have been declining at a phenomenal rate, almost fast enough for it to qualify as a threatened species according to IUCN criteria. For this reason it was treated as Near-threatened in the latest Asian Red Data Book.*

[*Pycnonotus cyaniventris cyaniventris*, Panti Forest Reserve, Malaysia. Photo: Jimmy Chew]

Status and Conservation

In general, the Pycnonotidae either are birds of open habitats or are resilient to forest degradation. In a study of primary and logged forest in Malaysia, A. D. Johns found that bulbuls did not drop out of logged habitats, and, indeed, several species increased after logging. Analyses in Africa have produced similar findings for many, but not all, species. The reason for this is partly that many bulbuls eat small berries, and the types of plant producing this resource often thrive in opened-up habitat. Some are also

*The **Yellow-eared Bulbul** is yet another abnormal* Pycnonotus *bulbul, previously placed in the monotypic genus* Kelaartia*, which may deserve resurrection. Two prominent features, its face-pattern and its voice, seem especially divergent. It is endemic to the uplands of Sri Lanka, where it is usually common in forest and associated secondary growth and thickets. Given the limited extent of its range, and the ongoing clearance of Sri Lanka's forests to supply the timber trade, or to make way for agricultural expansion and urbanization, it is classified as Near-threatened.*

[*Pycnonotus penicillatus*, Sri Lanka. Photo: Greg & Yvonne Dean]

generalists, able to switch between an insect-based diet and a fruit-based one according to conditions. This gives them much more ecological flexibility than is possessed by many species in other groups. Some African bulbuls, particularly insectivorous ones, however, have more specialized dietary requirements and foraging strategies that render them unable to cope with severe habitat degradation. Nonetheless, it remains perhaps somewhat surprising that 13 bulbul species, almost 10% of the family, are currently considered at risk of global extinction according to IUCN criteria.

The Straw-headed Bulbul, classified as Vulnerable, was once a common and widespread bird, but it has suffered catastrophic declines in its population and contractions in its range. This is principally because of the rampant cagebird trade in South-east Asia (see Relationship with Man), particularly in Indonesia. The species has been extirpated in Java, and numbers in Myanmar, Thailand, Sumatra and Kalimantan are now extremely low. The stronghold is Malaysia, where reasonable populations survive in protected areas such as those at Taman Negara and the Danum Valley. It is not found in tall rainforest, preferring instead the second-growth and shrubby habitat fringing lowland rivers. While there has undoubtedly been a problem of loss of riverine habitat, the species is tolerant of a fair degree of habitat degradation. Its absence from numerous apparently suitable sites is the result of extreme trapping pressure. This bulbul is a very popular cagebird because of its powerful and melodious song (see Voice). It is still commonly traded in bird markets in Bangkok, Thailand, and Jakarta, Java, but most of the individuals which continue to fuel this trade are trapped in and around their remaining Malaysian strongholds. Strict legal protection of this species is clearly vital if it is to survive this pressure. Protected areas require constant surveillance and patrolling if they are to repel the frequent visits of the trappers, who visit even the most remote localities. One result of the trade in Straw-headed Bulbuls is the establishment of a small population on Pulau Ubin and elsewhere in Singapore, founded by escaped captives. This is one of the only populations of the species that has been expanding of late.

Styan's Bulbul (*Pycnonotus taivanus*), also Vulnerable, presents another interesting case. The threats to it are, however, more to do with genetic interference than with habitat loss. Although native habitat in its range is being degraded, this is not, in itself, a problem, since Styan's Bulbul generally prefers secondary and shrubby vegetation. Nevertheless, partly as a consequence of habitat alteration, the ranges of this species and of the closely related Light-vented Bulbul now overlap in several areas, and the two species hybridize readily. Genetically pure Styan's Bulbuls are retreating in range, and are now found only in the coastal mountains of south-east Taiwan. The spread of hybrids has been accelerated by the release of large numbers of captive bulbuls for religious purposes (see Relationship with Man). This has created new epicentres of hybridization. There is, therefore, a real danger that the pure strain of Styan's Bulbul may disappear as a result of genetic swamping by the Light-vented Bulbul. This problem should be countered by the control of releases, and possibly by culling the Light-vented Bulbul population in overlap zones. Even so, the matter is a very difficult one to address. The possibility of establishing a refuge with a buffer zone, from which all Light-vented Bulbul types are removed, has been proposed.

*The **Scaly-breasted Bulbul** is treated as Near-threatened because it is restricted to the vanishing forests of the Sundaic region. In Malaysia and Sumatra, however, it remains moderately common, at least on humid submontane slopes where forest cover is relatively extensive. This is fortunate as it is perhaps the most beautiful bulbul, a little gem in a family famed for dreary plumage. Small groups forage actively in the canopy, sometimes accompanying mixed-species flocks, their plumage and behaviour often recalling tanagers (Thraupidae) in Andean cloudforests.*

[*Pycnonotus squamatus*, Hong Kong Park Aviary. Photo: Ray Tipper]

*The **Black-and-white Bulbul** is unusual in its plumage pattern and unpredictable movements. The male is mostly black but for a pair of strikingly white shoulders, while the female is duller and browner. It often appears in numbers at certain sites, stays for a few weeks or months, then disappears again. This nomadic tendency suggests some degree of specialization that probably renders it more susceptible to habitat fragmentation. This fact, and the rampant clearance of lowland forest in the Sundaic region, justifies its allocation to the Near-threatened category.*

[*Pycnonotus melanoleucos*, Crocker Range National Park, Sabah, Borneo. Photo: Doug Wechsler/ VIREO]

Although common at some sites in south-central India, the Yellow-throated Bulbul is extremely local and occurs in very few protected areas. It is thought to be declining, as its habitat is being cleared in many areas; this habitat loss is due to quarrying for granite, grazing, the collecting of wood for fuel, and agricultural expansion. Although the species is protected within Mudumalai and Sri Venkateshwara Wildlife Sanctuaries, further surveys are needed in order to attempt to clarify its full distributional range, and key sites should be given official protection. This bulbul, too, is placed in the conservation category of Vulnerable.

Naturally confined to a small area of the Albertine Rift region of DRCongo, Prigogine's Greenbul (*Chlorocichla prigoginei*) is listed as Endangered. This is because it is estimated to have a range of only 870 km² and is restricted to mid-altitude forest which is under particularly intense pressure for conversion to agricultural land and local logging. Human population pressures in the two areas in which the bird is known, north-west of Lake Edward and on the Lendu Plateau, are extremely intense; in fact, almost all forest on Lendu has been cleared. Information is, however, scanty owing to the continuing political unrest in the region. The prospects for Prigogine's Greenbul do not seem rosy. One hope is that it may yet be found to occur in other remaining forests in this poorly known region.

The mysterious Liberian Greenbul is one of three globally threatened pycnonotids confined to the Upper Guinea forests of West Africa. It is the only bulbul currently listed as Critical, this being attributable to its tiny range, confined to the type locality, in an area known to be subject to logging and clearance for subsistence agriculture. The security situation in the region has prevented research or conservation effort but is known to have exacerbated the short-term exploitation of the forests on which the greenbul depends. The taxonomic status of this species, however, is not established unequivocally, and the possibility remains that it is an aberrant form of the much more widespread and common Icterine Greenbul (see Systematics). Resolution of this issue is an important conservation priority.

Both of the other two threatened Upper Guinea bulbuls, the Green-tailed Bristlebill and the Yellow-bearded Greenbul, are much more widely distributed within West African forests, having similar ranges from south-east Sierra Leone east to south-west Ghana. That they are categorized as Vulnerable reflects the rampant deforestation to which this region is subject. A combination of commercial logging and agricultural intensification by the growing human population has meant that remaining forests are becoming increasingly fragmented and threatened. On a more positive note, however, following extensive survey work in the region and as a consequence of a better appreciation of their diagnostic characters, both species have been found in more of the remaining forest reserves than was originally suspected. Both are also known to be present in a number of national parks and other protected areas in the region, although, in many cases, these areas are at risk from a mixture of political instability, ineffective implementation of legal protection and chronic encroachment. Moreover, the presence of these species in forest reserves is, in any case, no guarantee of protection, since many such reserves are "production" forests, scheduled for varying degrees of exploitation in the future.

The Hook-billed Bulbul (*Setornis criniger*) is locally fairly common in Borneo, but scarce in Sumatra. Massive rates of deforestation and forest fires have, in recent years, reduced the total area of peatswamp-forest and *kerangas* (heath-forest), the principal habitats of this species. In Borneo, it is fairly common in Tanjung Puting National Park, in Kalimantan, and scarce at Danum Valley, in Sabah, and Gunung Mulu and Similajau National Parks, in Sarawak. Continued protection of these areas is essential, as is a higher profile for the conservation of peatswamp-forest and *kerangas* in the Sundaic region. Given the paucity of distributional information about this bulbul, further surveys are needed to attempt to clarify its status and distribution in more remote regions of Sumatra and Borneo. It is listed as Vulnerable.

Formerly common, the Nicobar Bulbul, too, is now classified as Vulnerable, following habitat destruction in its restricted range as a result of conversion to coconut plantations, expansion of human settlements and infrastructural development. A further threat is thought to come from competition with the introduced Red-whiskered Bulbul; the native Nicobar species seems to suffer wherever the introduced bulbul thrives (see below). The island of Tillanchong, just 17 km² in extent, is uninhabited and protected as a reserve. The largest numbers of Nicobar Bulbuls, however, have been seen on Katchall and Teressa Islands, and conservation action should be focused here. Control of the Red-whiskered Bulbul population should be considered.

Another member of the genus *Ixos*, the Streak-breasted Bulbul, is considered Endangered because of its very small, fragmented and declining range. It occurs on four islands of the Philippines: Tablas, Romblon, Siquijor and Cebu. Despite its tolerance of degraded habitats, it is threatened by deforestation. Indeed, it had been thought to be already extinct on Cebu, but a few recent

*One of the most poorly known of all bulbuls, **Finsch's Bulbul** is an inhabitant of dense Sundaic forests. It is currently grouped with* Alophoixus*, but seems rather divergent, and possibly deserves re-allocation to a monotypic genus. Although apparently scarce, it is difficult to assess to what extent this impression is exaggerated by its dull plumage, lack of notable song and retiring habits, all of which make it easy to overlook. Along with many sympatric species, it is classified as Near-threatened due to the catastrophic loss of lowland forest in south Thailand, Malaysia and west Indonesia.*

[*Alophoixus finschii*, Panti Forest Reserve, Malaysia. Photo: Ong Kiem Sian]

sightings in or near the Tabunan Reserve give cause for hope. Little suitable habitat remains on Tablas and Romblon, and the largest surviving population is on Siquijor, where a population of several thousand individuals is thought to be present. Protection of the remaining habitat on all islands is urgent, not least because the subspecies on Tablas and Romblon, *cinereiceps*, may merit treatment as a separate species (see Systematics).

Also an island inhabitant, the Mauritius Black Bulbul is currently listed as Vulnerable. Once one of the island's most widespread and common endemic birds, it has become confined to a very limited area of Mauritius, with a population estimated in 1993 to number about 280 pairs. The decline in its fortunes is due primarily to habitat destruction; this pycnonotid is largely reliant on native vegetation, as the invasive exotics do not provide the fruit or insects on which it depends for food. In addition to the loss of natural forest, nest predation by introduced mammals such as rats and crab-eating macaques (*Macaca fascicularis*), coupled with competition from introduced Red-whiskered Bulbuls and Common Mynas (*Acridotheres tristris*), appear to be restricting the bulbul's population. Mauritius Black Bulbuls occur in Black River Gorges National Park, but this covers only part of the species' current range, and some areas of remaining critical habitat are not included in any protected area. The rehabilitation of native ecosystems in Conservation Management Areas, including the exclusion of introduced animals and the removal of exotic vegetation, offers hope in the longer term. Other conservation initiatives being considered are the eventual translocation of some native bulbuls to neighbouring islets once the latter have been restored. There are plans for trial translocations of captive-reared individuals over the next few years.

Notwithstanding the fact that they have recently been shown not to be true bulbuls (see Systematics), two erstwhile members of the genus *Phyllastrephus* from Madagascar certainly merit their classification as globally threatened. Both are listed as Vulnerable. The Dusky Tetraka (*Xanthomixis tenebrosus*) is a puzzle. With the recent rediscovery of the Sakalava Rail (*Amaurornis olivieri*), this tetraka remains perhaps the least known of Madagascar's extant bird species. This is partly a consequence of misidentification; it has in the past been confused with other species because of a lack of appreciation of the characters by which it can be identified in the field. Although this is still true to a degree, it has recently been demonstrated that this tetraka is more distinctive than was hitherto appreciated, which, in turn, means that there has to be some uncertainty regarding a number of earlier, unsubstantiated field records. The species must, however, be rare and local, since many recent surveys across a large part of its potential range have drawn a blank. The Dusky Tetraka appears to be an inhabitant of undisturbed lowland and mid-altitude forest, with confirmed records, such as specimens, only from a limited area of north-east Madagascar. The remaining forests of this region are threatened by clearance for cultivation by subsistence farmers, resulting in increasing fragmentation and progressively more degraded regrowth. The few recent confirmed records have come from the protected areas of Marojejy and Zahamena National Parks, but further fieldwork to locate other populations, and to develop a fuller understanding of the species' habitat requirements and other factors limiting its population and distribution, is urgently needed.

The other globally threatened Malagasy species, Appert's Tetraka (*Xanthomixis apperti*), was not described until 1972 and has an extremely localized distribution in south-west Madagascar. Its population is estimated to number fewer than 2500 individuals, confined to Zombitse–Vohibasia National Park and, some 50 km to the west of there, the Analavelona forest. Zombitse and Vohibasia forests were threatened mainly by clearance for maize (*Zea*) cultivation and charcoal production but, thanks to conservation efforts, including the creation of the national park, there has been no further clearance for several years. Analavelona forest is not managed for conservation, but it is relatively isolated and clearance is not thought to be an imminent threat.

In addition to the 13 globally threatened species mentioned in the preceding paragraphs, 14 pynonotids, a further 10% of the family's members, are currently considered Near-threatened. Ten of these are Asian species: Finsch's Bulbul, the Buff-vented Bulbul (*Iole olivacea*), two species of *Ixos* and six species of *Pycnonotus*. Several of these are still common birds, but are thought to be at risk because of their restriction to low altitudes in the Sundaic region, where forest loss is occurring at a very rapid pace, and where population declines must consequently be steep. In Africa, the Cameroon Montane Bulbul and two *Phyllastrephus* greenbuls are Near-threatened, and the Grey-crowned Tetraka of Madagascar is included in the same conservation category. Almost all of these pycnonotids have suffered habitat loss, in some cases extensively so, and it is important that their populations be monitored.

Baumann's Greenbul is a very poorly known species, currently placed in the category of Data-deficient. It has been found at some 30 localities in its West African range, and appears to be

Many bulbuls in Africa and Asia are abundant and conspicuous as a result of their versatility and opportunism. It is perhaps surprising, therefore, that 13 species, almost 10% of the family, are considered at risk of global extinction. One of these is ***Appert's Tetraka****, a Madagascan endemic, which is thought to number fewer than 2500 birds. All are found in two protected areas: Zombitse-Vohibasia National Park and the Analavelona forest. Until recently these vital fragments were being whittled away by clearance and charcoal production, but conservation efforts seem to have slowed this process.*

[*Xanthomixis apperti*, Zombitse-Vohibasia National Park, Madagascar. Photo: Brenda Holcombe/ Windrush]

*The **Straw-headed Bulbul** is a remarkable bulbul on account of a suite of unique features, amongst which can be listed the tough carpet of bristle-like feathers on its forehead, the large size, and the phenomenally powerful and melodious song. Sadly, these features make it a popular cagebird in South-east Asia, and it is mercilessly trapped as a result. Once common and widespread, it has disappeared from Java and probably Myanmar, while populations in Thailand, Sumatra and much of Borneo are now dangerously small. It is listed as Vulnerable, and requires a concerted programme of conservation action to address the threat of excessive trapping.*

[*Pycnonotus zeylanicus*, Bukit Batok Nature Park, Singapore. Photo: Jimmy Chew]

rare. Because of its skulking behaviour, its lack of distinctive field characters, and its frequent occurrence in degraded habitats, however, it is often overlooked or misidentified. Moreover, the literature contains information based on incorrect field identification, thereby confusing the situation. Bearing in mind its habitat requirements, this greenbul is thought likely to be more common and widespread than records suggest.

Mention should also be made of another poorly known species, the Blue-wattled Bulbul, also classified as Data-deficient. This is known from only two specimens, the first collected in 1901 at about 500 m on the upper Kayan River, in Kalimantan, and the second taken in northern Sumatra in 1939, and described as a separate race. The only recent reports involve a series of five sightings in 1992 at Kuala Belalong Field Studies Center, in Brunei. This bird is an enigma if ever there was one. Either it is extremely rare and thinly distributed over a wide range, or it is a strange morph or even a hybrid. The evidence for its being a morph is very slender, as it does not look like any other species in its range, differing in shape and in having a bright swollen eyering. The evidence for hybrid status is equivocal (see Systematics). It could be a habitat specialist restricted mainly to a habitat type infrequently visited by ornithologists, or perhaps it may be simply overlooked because it is relatively inconspicuous. In view of the number of observers visiting some lowland-forest sites in Sumatra and Borneo, it seems unlikely that this bulbul, if it does indeed occur at those sites, would be overlooked. The possibility that it may be a habitat specialist is tempting, but this idea loses ground when one considers that the Sumatran specimen was found in shrubs on a river island, while the recent Brunei records were mostly in the canopy of undisturbed rainforest. These observations do not point towards specialization. So little is known about this pycnonotid that nothing more can be said about it at present. Fieldwork is the most important requirement if this elusive bird is to be tracked down and its true identity unmasked.

One of several consequences of the cagebird trade (see Relationship with Man) is that it can lead to changes in a species' distribution. Many bulbuls, having escaped or been released from captivity, have established thriving extralimital colonies as far afield as Miami, in the south-east United States, Hawaii, Polynesia, Mauritius and Australia. A good example of shifting distribution resulting from the cagebird trade is provided by the Red-whiskered Bulbul. In Thailand and north Peninsular Malaysia, part of its natural range, this was once one of the commonest open-country bird species, but it is now virtually extinct in most of this region, the victim everywhere of excessive trapping. Perhaps the healthiest population in the Malay Peninsula is now the small one in Singapore, far outside the species' natural range; first reported in 1925, this was founded by escapees.

Bulbuls fare well in new environments because they are such opportunistic generalists. This is well illustrated, for example, by the success of the Red-whiskered Bulbul around the Indian Ocean. In the Mascarene Islands, the recent introduction of this species has been followed by a very rapid expansion of the population. The same species was released on the Nicobars in the 1870s, when W. Davison found a small party of them on the island of Camorta shortly after the first release. He commented that they were "probably those sent there from the Andamans by Mr. Homfray; they were in the cotton field and had apparently made themselves quite at home." He added that, on 16th January, eight or ten Red-whiskered Bulbuls were released in the village of Orong, on Car Nicobar, and that when he saw them several hours afterwards "they seemed to have taken quite kindly to the place, and were looking for insects in the brushwood bordering the jungle". These introductions resulted in the Red-whiskered Bulbul invading many of the Nicobar islands, much to the detriment of the endemic Nicobar Bulbul, which is now much rarer and, as mentioned above, is globally threatened. This illustrates how readily bulbuls can adapt to new environments, and the potential negative repercussions of allowing them to do so.

Genus *SPIZIXOS* Blyth, 1845

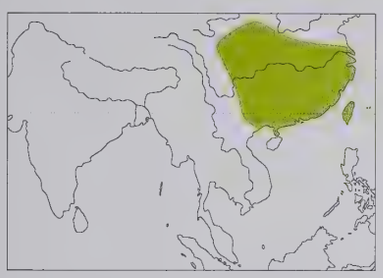
1. Crested Finchbill

Spizixos canifrons

French: Bulbul à gros bec **German**: Finkenbülbül **Spanish**: Bulbul Picogrueso
Other common names: (Crested) Finch-billed Bulbul

Taxonomy. *Sp[izixos]. canifrons* Blyth, 1845, Cherrapunji, Khasi Hills, Meghalaya, India.
Forms a superspecies with *S. semitorques*. Race *ingrami* only doubtfully distinct, as differences seem to fall entirely within range of variation of nominate; further research required to assess its validity. Proposed races *nobilis* (Assam, in NE India) and *laotianus* (Laos) considered too poorly differentiated to warrant recognition, and thus merged in, respectively, nominate and *ingrami*. Two subspecies provisionally recognized.
Subspecies and Distribution.
S. c. canifrons Blyth, 1845 – NE India (Assam, Meghalaya, Nagaland, Manipur, Mizoram, possibly also NE Arunachal Pradesh) and W Myanmar.
S. c. ingrami Bangs & J. C. Phillips, 1914 – E Myanmar, S China (SW Sichuan, N, W & S Yunnan), NW Thailand, N Laos and NW Vietnam (W Tonkin).
Descriptive notes. 19–22 cm; 44 g. Medium-large, noisy, conspicuous bulbul with short, conical bill. Most of head is dark grey, forehead pale grey, chin, throat, mask and rear crown blackish, some pale grey on lower face and ear-coverts,crown feathers elongated to form erect pointed jet-black crest; hindneck to uppertail-coverts olive-green; wings dusky olive, prominent yellow-green fringing on outer webs of remiges; tail similar, but with broad black terminal band; breast and flanks olive-green, becoming yellower on belly and undertail-coverts; iris dark brown to reddish-brown (hazel); bill pale yellowish-horn, black gape; legs pinkish or brownish-flesh, claws brown. Sexes similar, but female noticeably smaller than male, with duller black crest and mid-grey throat. Juvenile is much duller, with short crest, very weak head pattern (greenish-yellow forehead, pale brown ear-coverts, contrasting blackish-brown crown and nape, brown throat), pale yellow-tinged underparts with dark brownish-olive breastband, less distinct tailband; iris dull brown, bill pale fleshy or dusky, feet and toes horny flesh. Race *ingrami* supposedly has greyer throat and duller olive-green underparts than nominate. Voice. Dry, bubbling, trilled song described as "purr-purr-prruit-prruit-prruit", also a loud, full, sputtering series of harsh and guttural but somewhat musical "squirr ki-kirr-kirr-kirr" that rises distinctly and ends abruptly. Oft-given calls include bursts of gritty, powerful rattles comprised of short, upward-inflected buzzes, "grz-grz-grz"; similar but drier rattles may be merged with song elements.

Habitat. Open and stunted evergreen and deciduous forest, montane scrub, secondary growth and grasses; fond of clearings overgrown with bamboo and brambles (*Rubus*). Commonest at 1200–2500 m, but ranges to 4000 m in breeding season, and occasionally down to 900 m (once to 300 m) in winter.
Food and Feeding. Feeds on seeds (e.g. millet, grass), beans, peas, various types of fruit (e.g. *Leucospectrum* in Myanmar); also insects, including small beetles (Coleoptera), moths (Lepidoptera) and dipteran flies. Feeds at all levels; insects occasionally caught in flight. When not breeding forms monospecific flocks, sometimes containing 50–100 individuals, or mixed flocks with *S. semitorques* (S China, N Vietnam); has been recorded as joining other bulbuls to feed in fruiting fig trees (*Ficus*).
Breeding. Mar–Jul; most pairs in Chin Hills (NW Myanmar) had nestlings by late Apr. Apparently breeds co-operatively, although evidence rather scant. Nest a compact cup of strong fibres and a few elastic twigs, often without inner lining, fixed between several upright twigs, or lodged in stout fork, usually 1–3 m up in low bush (e.g. *Rubus*) or small tree, often in dense, low secondary growth; several nests in Chin Hills were made of corkscrew-like tendrils of a creeper plaited to-



gether to form shallow saucer, most unlined, or lined with a trace of fluff or fine grass. Clutch 2–4 eggs, usually 2; no information on incubation and fledging periods.
Movements. Resident; does not usually descend to lower altitudes in harsh weather, but has been recorded down to 300 m in cold season.
Status and Conservation. Not globally threatened. Fairly common in highlands of Myanmar and N Thailand, but scarce in China. Nominate race possibly occurs also in SE Bangladesh (reported from Chittagong Hills, but no definite records). Much of its range is difficult of access, and overall population must be large and relatively secure. This is one of few montane Asian species to benefit from slash-and-burn agriculture, as this promotes its favoured scrubby habitat. It is a popular cagebird, but constant low-level extraction has not reduced its population. Can be a pest in montane gardens, where flocks can damage crops such as peas etc.
Bibliography. Ali & Ripley (1996), Bingham (1903), Bingham & Thompson (1900), Cheng Tsohsin (1987), Deignan (1945), Delacour (1926), Dickinson *et al.* (2002b), Duckworth, Salter & Khounboline (1999), Étchécopar & Hüe (1983), Grimmett *et al.* (1998), Harington (1909a), Hopwood & Mackenzie (1917), Hume (1878b, 1888), Lekagul & Round (1991), MacKinnon & Hicks (1996), MacKinnon & Phillipps (2000), Meyer de Schauensee (1984), Morris (1889), Pershouse (1916), Rasmussen & Anderton (2005), Ripley (1982), Rippon (1901), Robson (2000), Rothschild (1921), Severinghaus (1978), Singh (1995), Smythies (1986), Stanford & Mayr (1940–1941), Stresemann & Heinrich (1939), Stuart Baker (1892–1893, 1922–1930), Venning (1912), Wickam (1918).

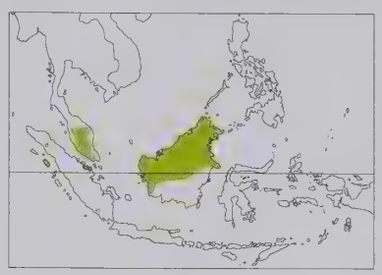
2. Collared Finchbill

Spizixos semitorques

French: Bulbul à semi-collier **German**: Halsbandbülbül **Spanish**: Bulbul Collarejo
Other common names: Swinhoe's Finch-billed Bulbul, Black-headed/Chinese Finchbill

Taxonomy. *Spizixos semitorques* Swinhoe, 1861, Minhou, Fujian, south-east China.
Forms a superspecies with *S. canifrons*. Two subspecies recognized.
Subspecies and Distribution.
S. s. semitorques Swinhoe, 1861 – C, S & SE China and N Vietnam (locally W & E Tonkin).
S. s. cinereicapillus Swinhoe, 1871 – Taiwan.

Descriptive notes. 21–23 cm. Nominate race has head mostly blackish-grey, blackest on forecrown and forehead, with white supraloral spot, white streaks on ear-coverts; white sides of nape forming half-collar, otherwise nape and extreme upper mantle grey; rest of upperparts olive-green, yellower on wings and tail, latter with broad blackish subterminal bar; whitish half-collar separates black throat from olive upper breast, this becoming flammulated with yellow on lower breast, and pure primrose yellow in centre of belly; iris blackish or reddish-brown; bill ivory or cream; legs pale brown or dark flesh. Differs from *S. canifrons* in lack of crest. Sexes similar, but female smaller than male. Juvenile has dark head markings replaced with mid-brown, ear-covert streaks less distinct, upperparts and wing-coverts darker. Race *cinereicapillus* is very like nominate, but crown, forehead and tail tip marginally paler, grey instead of black. Voice. Song (in China) a quick, steadily paced sequence of 3–6 trisyllables (first and last notes equal in pitch, middle note higher), sometimes terminating in double syllable, e.g. "chuwichu-chuwichu-chuwichu-chuwi"; during singing bouts, songs are given after brief pauses, usually 5–10 seconds. One call an upslurred rippling "wirrrrp", often in series, and merging into song phrases.
Habitat. Open woodland, second growth and scrub in montane regions, including brush-covered ravines and hillsides covered in swordgrass (*Brachiaria decumbens*); often found around habitations and at edge of larger towns. Seems commonest at 1200–1500 m, but ranges considerably lower and higher.
Food and Feeding. Known to eat both fruit and insects; stomachs of specimens contained a cicada (Cicadidae), "field-bugs" and some berry seeds. Noted as perching prominently on bare twigs protruding from shrubbery, dropping into dense cover when disturbed. Gathers in monospecific flocks, often of 20–30 individuals, outside breeding season; sometimes flocks with *S. canifrons* (S China, N Vietnam).
Breeding. Mar–Jul; in S China thought to nest relatively late, usually May onwards, and to have protracted breeding season; probably two broods. Nest of strips of bark, leaves and leaf skeletons, grasses and other pliable material, woven into compact, deep cup with strong walls, although described by some authors as flimsy and shallow; usually 0·5–3 m above ground in brambles (*Rubus*) or other low scrub, in bunch of swordgrass, or in low tree. Clutch 3–4 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Locally fairly common or even very common, especially in parts of Taiwan and S China. Tolerates highly man-modified environments and is therefore not under any immediate threat. Occurs in a variety of protected areas, including Wolong Giant Panda Reserve, in Sichuan (China).
Bibliography. Caldwell & Caldwell (1931), Chang James Wanfu (1993), Cheng Tsohsin (1987), Collar (2004c), Dickinson *et al.* (2002b), Étchécopar & Hüe (1983), Inskipp *et al.* (1996), Lewthwaite (1996), MacKinnon & Phillipps (2000), Meyer de Schauensee (1984), Nguyen Cu *et al.* (2000), Robson (2000), Severinghaus (1978), Strange (2002), Swinhoe (1863), Traylor (1967), Tsai Hangyeh (1985), Zhang Cizu *et al.* (1997), Zheng Guangmei & Zhang Cizu (2002).



Genus *PYCNONOTUS* Boie, 1826

3. Straw-headed Bulbul

Pycnonotus zeylanicus

French: Bulbul à tête jaune **German**: Gelbscheitelbülbül **Spanish**: Bulbul Cabeciamarillo
Other common names: Straw-crowned/Yellow-crowned Bulbul

Taxonomy. [*Sturnus*] *zeylanicus* J. F. Gmelin, 1789, Sri Lanka; error = Java.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species was previously placed in monotypic genus *Trachycomus* (and for long known by synonym "*T. ochrocephalus*"); a return to its own genus perhaps justifiable on vocal, behavioural and morphological grounds. Monotypic.
Distribution. Peninsular Malaysia, Singapore, NW & SW Sumatra (including Nias I) and Borneo (except S).

Descriptive notes. 28–29 cm; 80–93 g. Large, noisy, uniquely patterned bulbul with robust bill, sturdy legs. Forehead, crown, lores and patch under eye are golden-yellow, offset by narrow blackish stripe from near nostrils back to (and protruding short distance behind) eye, and broad black submoustachial streak; feathers on forehead stiffened and brush-like, tinged tawny; nape, mantle and back brownish-grey, narrowly streaked ash-grey, and fringed greenish-brown (becoming greener towards rump); rump and uppertail-coverts dull olive-green with brighter olive fringing and tipping; wings and rounded tail brown on inner webs, olive-green on outer webs, with brighter fringes (rectrices tipped grey-white when fresh); chin, throat and breast whitish, breast heavily mottled greyish-brown with narrow white shaft streaks; rest of underparts more evenly sullied pale grey-brown, palest on mid-belly, thighs ashy-brown, undertail-coverts buff with yellow lateral fringing; iris red or chestnut; bill black; legs brownish-black, claws black. Sexes similar, female on average slightly smaller and may have duller, dark red-brown iris. Juvenile is duller, with less pronounced streaking, browner head, brown or light brown iris. Voice. Song frequently given, heard all year, powerful, mainly of repeated 2-note phrases producing rich, melodious, bubbling, rising and falling cadence, often sustained in antiphonal duet or chorus. Also semi-constant low gurgles or weak chattering when foraging and prior to roosting.
Habitat. Almost exclusively along banks of rivers and streams, usually where bordered by broadleaf evergreen forest and secondary growth; often found in low berry-bearing trees and shrubs overhanging water. Ventures less often into park-like habitat, scrub, mimosa (*Albizia*) plantations and cultivation, rarely into mangroves, and avoids continuous forest. Commonest in lowlands, to 240 m in Peninsular Malaysia, regularly (at least historically) to 1500 m in mid-montane forested ravines in Borneo (highest record 1800 m).
Food and Feeding. Diet primarily berries and other fruit, and seeds; also arthropods, some molluscs, occasionally small invertebrates. Eats figs (including *Ficus microcarpa* and *F. trichocarpa*), mistletoe berries (Loranthaceae), wild "cherry" (*Muntingia calabura*), and many other fruits; also small seeds and rush heads; in Singapore, visits the common exotic palm *Ptychosperma macarthurii*, taking nuts while hanging below, rather than perched on the fruit spike. Arthropods taken are spiders (Araneae) and a range of insects, including, among others, beetles (Coleoptera), both terrestrial and flying, bees (Hymenoptera), mantids, cockroaches (Blattodea), orthopterans. Known to eat molluscs (e.g. small riverine snails), and small vertebrates such as flying lizards (*Draco*). Items brought to nestlings and fledglings include, besides small unidentified fruit, spiders, caterpillars and stick-insects (Phasmida). Unlike many forest bulbuls, often feeds on the ground. Has been seen to catch large caddis flies (Trichoptera) in flight 2–3 m above water, and can catch slow-flying beetles in flight. Usually found in small family groups, often of 3–6 individuals (but regularly up to eight), from understorey to canopy.
Breeding. Usually breeds in Jan–Sept; in Peninsular Malaysia nest-building recorded Dec–Jul and laying in Jan–Jun and Aug; in Borneo, laying recorded Dec–Mar in Kelabit Highlands and eggs and young chicks in Nov and Aug in E Kalimantan. Extra-pair adults (helpers) sometimes feed fledglings, and at regular breeding site in Singapore a territorial group of four adults perched near nest with chicks (but number of individuals delivering food to nest not determined); these observations, and the fact that species often lives and sings throughout year in groups, indicate that cooperative breeding likely, but further research required to clarify breeding system. Nest a fairly large, shallow, untidy cup built from thin twigs, rootlets, grass and plant fibres, in Peninsular Malaysia lengths of fine creeper stalks and rhizomes of a small climbing fern (*Drymoglossum piloselloides*) often incorporated as binding and camouflage; nests found 1·5–6 m above ground, usually in branch fork of small tree along stream (sometimes overhanging water) or standing out from other vegetation in clearing or second growth, less often in low orchard or plantation tree, e.g. mango (*Mangifera*) or rubber (*Hevea*). Clutch 2 eggs; incubation and fledging periods unrecorded; nestlings and fledglings tended by both pair-members; fledged broods of two recorded.
Movements. Resident.
Status and Conservation. VULNERABLE. CITES II. Generally uncommon; very locally more common. Apparently extinct in S Myanmar, S Thailand and Java. A very popular cagebird in Indonesia and SE Asia, chiefly because of its rich and powerful voice. Intensive trapping the main threat, having eliminated this species from much of its range in recent decades; widespread habitat destruction along waterways a contributory factor, but it can tolerate moderate to heavy degradation where not persecuted. Was always marginal in Myanmar, where no recent records; has been rare in S Thailand for several decades owing to trapping, and presumed now extinct. Once abundant in Sumatra and E Java; after huge population crash, now rare and extremely local in Sumatra and extinct in Java. In Peninsular Malaysia, more or less common until 1990s, now irregular and uncommon to sparse throughout except in a few protected areas. Locally secure in Borneo (Sabah, Sarawak, Brunei and interior Kalimantan), but trapping pressure intense, at least in Kalimantan. Only in Singapore has status improved; was rare, if not extinct, on the main island by early 1980s, but ex-captives are prospering and expanding numbers in more or less secure parkland and in the increasing amounts of still suitable habitat held by the military; on Ubin I estimated 32 breeding pairs, at average density of 1 pair/32 ha, during May–July 2001. Because they are noisy inhabitants of linear habitat, breeders are easy to find and monitor; accessible rivers should be monitored where possible. This pycnonotid has strongholds in some large protected areas, including Taman Negara National Park, in Peninsular Malaysia, and Danum Valley Conservation Area, in Borneo (Sabah), and strict long-term protection of these sites is vital.

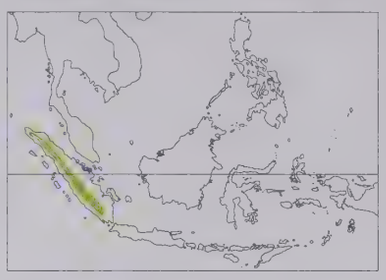
4. Striated Bulbul

Pycnonotus striatus

French: Bulbul strié **German**: Streifenbülbül **Spanish**: Bulbul Estriado
Other common names: Striated Green Bulbul

Taxonomy. *Tricophorus striatus* Blyth, 1842, Darjeeling, West Bengal, India.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. This aberrant species perhaps merits placement, along with *P. leucogrammicus*, in a separate genus, *Alcurus*. Validity of race *paulus* dubious, as features seem to fall within range of variation of nominate; further investigation required. Putative race *arctus* (NE India) lacks constant differences and is merged with nominate. Two subspecies provisionally recognized.
Subspecies and Distribution.
P. s. striatus (Blyth, 1842) – Himalayas in C Nepal, Bhutan and NE India (Uttar Pradesh, West Bengal, NE Arunachal Pradesh, hills of Meghalaya, Assam and Nagaland S to Mizoram).
P. s. paulus (Bangs & J. C. Phillips, 1914) – much of Myanmar (S to N Tenasserim), S China (Yunnan S of Likiang Range), mountains of W & N Thailand, N Laos and N Vietnam (W Tonkin).



Descriptive notes. 21–23 cm; 45–60 g. A large, almost entirely streaked, rather long-tailed bulbul with long, tapered crest. Cheeks and crown are greenish-brown, finely streaked white (including on dusky-olive crest); mantle, rump and uppertail-coverts bright olive, streaked white; wings and tail rich olive-green, tail browner towards tip, outer rectrices with small yellowish-white tips; lores, eyering, throat and vent bright yellow, lower throat lightly spotted or stippled blackish; breast dark grey becoming dark olive-green on belly, all broadly streaked yellowish-white; iris deep brown; bill blackish or plumbeous slate; legs and claws dark brown or plumbeous black. Sexes alike. Juvenile is slightly duller above, with much shorter crest, less distinct streaking overall, and much paler yellow on throat, belly and vent. Race *paulus* is supposedly slightly larger, with buffy-olive crest, and fringes of breast feathers greyish, rather than brownish. Voice. Less vocal than most bulbuls. Calls a hard "pyik...pyik", or harsh slurred "djrrri"; also repeated loud, short, jolly phrases of simple strident notes, often in couplets separated by brief pause, e.g. "schew-whit! tchi-whit!" or "cha whik! tu-tu", continuing thus with evenly spaced pauses; may slip into more monotonous, simpler 2-note "tchick-whirk tchik-whirk...", sometimes slowing pace markedly. More complex variants sound like "tchoidi-chik tchoik", or "tchip-it, chi'chi-guweeez" with last note an upslurred guttural buzz. Less often a more involved song with same hard metallic musical quality, but with several notes strung together in quickly descending, almost warbling series.
Habitat. Lower-stature broadleaf evergreen forest, semi-deciduous forest and moist oak-rhododendron (*Quercus–Rhododendron*) forest, forest characterized by *Bucklandia* and Lauraceae; often emerges at edges but never ventures far from relatively tall trees. Commonest in mid-altitude band at 1200–2400 m, sometimes ranging to 3000 m; occasionally down to 300 m in winter.
Food and Feeding. Eats berries and many insects. Birds in Myanmar seen to forage on *Maesa*, *Viburnum*, *Bucklandia*, *Ilex*, *Heptapleurum* and other berries; stomachs of specimens in N Thailand contained only insects. Forages singly or in pairs, in non-breeding season also in small parties of up to twelve individuals. Forages from bushes upwards, but most often in treetops, often hidden among dense foliage, and perching in open much less often than do most members of genus. Insects often caught in short aerial sallies from tops of trees.
Breeding. Little reliable information. Breeds May–Jul. Reported nests in each case a robust, compact cup composed of fine elastic twigs, coarse fern roots, twigs, dead stems and scraps of moss, inner lining of very fine shreds of grass, placed low in dense undergrowth, usually in thick bush or bamboo clump, close to ground and hidden by twigs and creepers; likely that, at least sometimes, nest placed much higher up in tree. Clutch usually 3 eggs, sometimes 2. No other information.
Movements. Resident, but subject to altitudinal movements. In parts of range, distinct movement to lower levels in cold season reported.
Status and Conservation. Not globally threatened. Generally fairly common throughout range. Thinly distributed in NE India, but total population there must be large in view of large area of suitable habitat surviving in West Bengal, Assam, Arunachal Pradesh and other NE states. Fairly common in Bhutan, where much habitat remains. Status in Myanmar unknown, but large amounts of unsurveyed habitat remain in highland regions. Local and uncommon in Nepal and much of N Thailand. Occurs in a range of protected areas, including Namdapha National Park, in India, Thrumshingla National Park, in Bhutan, and Doi Inthanon National Park, in Thailand.

5. Cream-striped Bulbul

Pycnonotus leucogrammicus

French: Bulbul rayé **German**: Strichelbülbül **Spanish**: Bulbul Rayado
Other common names: Streaked/Striated/Sumatran Bulbul

Taxonomy. *Ixos leucogrammicus* Statius Muller, 1836, Sumatra.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. This aberrant species perhaps merits placement, along with *P. striatus*, in a separate genus, *Alcurus*. Monotypic.
Distribution. Hill ranges of W Sumatra (Aceh S to Sumatra Selatan).

Descriptive notes. 17–18 cm. Medium-small, streaky bulbul. Forehead and crown are dark greyish-brown finely streaked pale, feathers slightly elongated to form modest crest (often partially raised); neck to uppertail-coverts slightly paler greyish-brown with fine white shaft streaks; upperwing and tail dark brown with dull olive fringes, these most distinct on secondaries and base of tail feathers; face strongly streaked white, chin and throat uniform creamy white; upper breast contrastingly dark olive, with creamy feather centres creating boldly scalloped effect which fades on lower breast, leaving rest of underparts uniform murky white, tinged yellow on vent and undertail-coverts; iris bright orange-yellow to reddish-brown; bill black, sometimes paler greyish at base; legs brown. Sexes alike. Juvenile undescribed. Voice. Said to have sharp and chirpy contact call; one vocalization is a steady trisyllable with first note highest, "tree, troo-troo", usually given every 5–10 seconds. Presumed song a rather quiet, throaty, mumbling, unmusical warble.
Habitat. Evergreen forest, edges and second growth in mountains, at 800–1900 m. In N of range found in forest and thick secondary vegetation between tobacco fields; in C & S parts likewise often seen at forest edges and roadsides where forest relatively intact.
Food and Feeding. Eats fruit, possibly also insects; stomachs of specimens from N Sumatra contained "fruitpeel, brown pips and a little pulp". Usually encountered singly or in pairs, sometimes as small (family?) groups, often accompanying mixed foraging flocks. Spends most time in middle storey or subcanopy.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Sumatra and Peninsular Malaysia EBA. Fairly common in mid-elevation forests; thought to be generally uncommon in N Sumatra, though much of this area barely investigated by ornithologists. Occurs in Kerinci-Seblat National Park and Bukit Barisan Selatan National Park.
Bibliography. Chasen & Hoogerwerf (1941), Inskipp *et al.* (1996), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Ripley (1943), Stattersfield *et al.* (1998), Tobias (1995), Tobias & Phelps (1994).

6. Spot-necked Bulbul

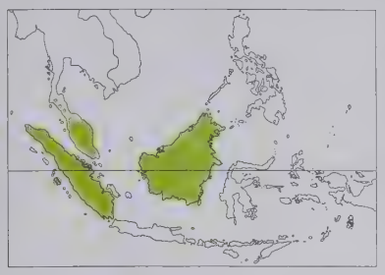
Pycnonotus tympanistrigus

French: Bulbul à cou tacheté **German**: Goldbürzelbülbül **Spanish**: Bulbul Cuellipinto
Other common names: Olive-crowned Bulbul

Taxonomy. *Ixos tympanistrigus* Statius Muller, 1836, Sumatra.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species placed by some earlier authors in subgenus *Alcurus*, alongside *P. striatus* and *P. leucogrammicus*, and similarity in plumage to *P. zeylanicus* noted by others. Taxonomic affinities need review, including analysis of morphology, voice, behaviour and genetics. Monotypic.
Distribution. Hill ranges of W Sumatra (Aceh S to Sumatra Selatan).

Descriptive notes. 16 cm. Medium-small, relatively rotund, brownish bulbul. Crown, nape and mantle are dull greenish-brown; cheeks and face whitish, tiny blackish barbs on malar and ear-coverts, narrow blackish submoustachial stripe; distinctive and conspicuous half-moon patch bordering rear of ear-coverts bright yellowish-white; wings and tail dark brown, outer webs of remiges and rectrices fringed dull olive; throat white; underparts whitish, strongly mottled brown, more uniformly brownish on flanks and lower belly, with yellowish tinge on crissum; iris yellowish-brown; bill and legs blackish-brown. Sexes alike. Juvenile undescribed. Voice. Disyllabic "tdip-diew", first note higher; presumed alarm note a repeated emphatic "jret-jret-jtry".
Habitat. Evergreen forest, edges and second growth; at 300–1400 m, usually commonest at mid-elevations (600–900 m).
Food and Feeding. Diet includes berries and other small fruits, possibly also some insects. Normally in pairs or very small (family?) groups in middle storey and canopy. Sometimes joins mixed-species foraging flocks, but often found independently.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Sumatra and Peninsular Malaysia EBA. Until recently was considered quite rare, with few records from relatively few sites. Has since been found widely in the Barisan Range in areas where forest cover remains extensive in altitudinal band occupied by this species. Although not imminently threatened with extinction, it is restricted to lower elevational zone than *P. leucogrammicus*, and is therefore more susceptible to catastrophic rate of deforestation currently affecting the lowlands and lower slopes of Sumatra. Population requires monitoring, and suitable habitat needs effective protection within key reserves, e.g. Kerinci–Seblat and Bukit Barisan Selatan National Parks.
Bibliography. Butchart & Stattersfield (2004), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Holmes (1996), Inskipp *et al.* (1996), MacKinnon & Phillipps (1993), MacKinnon *et al.* (2000), van Marle & Voous (1988), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Tobias (1995), Tobias & Phelps (1994).

7. Black-and-white Bulbul



Pycnonotus melanoleucos

French: Bulbul demi-deuil **German**: Trauerbülbül **Spanish**: Bulbul Blanquinegro

Taxonomy. *Microtarsus melanoleucos* Eyton, 1839, Melaka, Peninsular Malaysia.

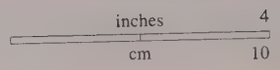
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species may merit isolation in a monotypic genus *Microtarsus* on grounds of morphology, voice and behaviour. Characters of putative race *proximus* (Siberut, in W Sumatra) fall within range of variation found throughout species' entire distribution. Monotypic.

Distribution. Extreme S Thailand, Peninsular Malaysia, Sumatra (including Siberut) and Borneo.

Descriptive notes. 16–18 cm; 23–33 g. Medium-small, quiet, relatively unobtrusive bulbul, as adult virtually unmistakable. Male is uniform blackish-brown, with contrasting upperwing-coverts and underwing-coverts mostly creamy white; tail rounded and all black; iris chocolate-brown to red-brown, perhaps even red; bill black; legs black or black-brown, occasionally bluish-grey. Female is slightly browner than male, with less white on upperwing-coverts (black of covert tips runs narrowly back along outer margins and shafts, forming grid pattern); some have wing panel tinged tawny-brown. Juvenile is much paler and browner, upperparts dark brown with ash-brown fringing (scaly effect), upperwing-coverts lacking white, but fringed with ashy olive on outer webs; tail dull brown, sometimes strongly tipped whitish; underparts off-white with shafts and tips variably sullied pale brown, giving slightly mottled or streaked effect, especially on chest; iris grey-brown. VOICE. Generally quiet. Occasionally a tuneless, clear, upward-inflected disyllable, variously transcribed as "hew-it", "too-wit", "chew-it", "kwe-it", "pet-it" or "tee-too"; similar call given as "cherlee", sometimes expanded to "cherlee-chlee-chlee-chee-chee". Sometimes several call notes given in steady sequence, producing effect not unlike the call (song?) of *P. atriceps*, but not so loud and clinky in tone.

Habitat. Broadleaf lowland evergreen forest (primary forest and selectively logged forest), mixed dipterocarp forest, second growth, and forest edge; also recorded in gardens in forested regions, peatswamp-forest, tidal riverine forest, dipterocarp/*kerangas* transition forest, and overgrown mimosa (*Albizia*) and rubber (*Hevea*) plantations. Tends not to venture far out into large clearings with scattered trees or shrubs. From hinterland of coasts to 1830 m, occasionally higher; commonest in lowlands.

Food and Feeding. Fruits; also eats caterpillars, but few reports of insects in diet. Seems partial to fruits of mistletoes (Loranthaceae), *Lantana* and *Melastoma*; one radio-tagged individual favoured fruiting vines. Observed to eat figs (including *Ficus microcarpa* and *F. obscura*) but, in contrast to forest-dwelling congeners, seems to ignore most fig species. Arboreal substrate-gleaner. Found at all levels of forest; often seen in canopy but also regularly caught in mist-nets, suggesting that some foraging occurs low down on fruiting shrubs. Travels singly or in small groups (mostly of 2–9 individuals), and ranges widely in search of fruit. Joins other bulbuls at fruiting trees, arriving in numbers that fluctuate from day to day.



Breeding. Breeds Jan–May. Nest cup-shaped, interior measurements of one were 7 cm wide × 3 cm deep, composed chiefly of sticks bound together by pieces of climbing plants, lined with same material admixed with a few dark fibres; placed in fork of branches, once 6 m up in upright fork of old rubber tree, once 1 m up in low horizontal fork of sapling. No other information.

Movements. Resident, but nomadic over wide area; often arrives in numbers in one locality, staying for a few weeks, and then disappearing altogether. In Peninsular Malaysia, one radio-tagged individual ranged over c. 8–18 ha per day and 50 ha in one week, roosting at different site each night. In partially cleared landscapes, individuals or groups move between forest patches. Occasional records at high altitudes, including one individual picked up dead at 3050 m, suggest that longer-distance movements occur.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Fairly common in Peninsular Malaysia and parts of Borneo, but often difficult to find because of its unpredictable irruptive movements; apparently rather rare in Sumatra. Formerly occurred in Singapore, but no recent records from there. Rampant clearance of lowland evergreen forest in Sundaic region must be causing drastic declines in this species' population, but its tolerance of patchy habitat, combined with its occurrence in submontane zone, suggests that it is under no immediate threat of extinction. Its nomadic tendencies, however, suggest some degree of specialization that may make it more susceptible to increasing habitat fragmentation. Occurs in a number of protected areas, e.g. Taman Negara National Park (Peninsular Malaysia), Gunung Leuser National Park (Sumatra) and Danum Valley Conservation Area (Borneo).

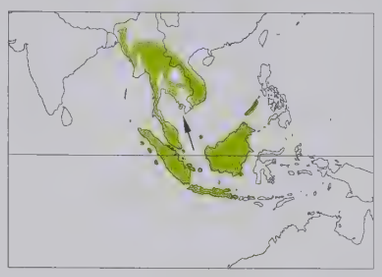
8. Grey-headed Bulbul

Pycnonotus priocephalus

French: Bulbul colombar **German**: Graukopfbülbül **Spanish**: Bulbul Cabecigrís

Taxonomy. *B[rachypus]. priocephalus* Jerdon, 1839, Periyar, Tamil Nadu, India.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species may merit separation in resurrected genus *Brachypodius*, alongside *P. atriceps* and *P. fuscoflavescens*. Species name often misspelt as "*poiocephalus*" owing to long-standing confusion in the literature. Monotypic.
Distribution. Western Ghats (from extreme S Maharashtra and Goa S to Kerala) and Palni Hills (Tamil Nadu), in SW India.



Descriptive notes. 17–19 cm. Small, active, peak-headed, olive-coloured bulbul. Anterior lores and forehead are bright greenish-yellow, rest of lores dull greenish (black feather bases visible from some angles); ocular region, ear-coverts, patch at base of lower mandible and malar streak dull green; crown, nape, side of neck and throat dark ash-grey; mantle, back and scapulars warm dark olive-green; loose and plush feathering of lower back and upper rump black, broadly tipped pale ashy green (appearing mottled green when flattened, barred black when raised); elongated uppertail-coverts bleached grey; flight-feathers blackish-brown, outer webs fringed bright olive-green (covering entire outer web on tertials); most of tail delicate ash-grey, black outer feathers broadly tipped same colour and fringed green on outer webs; chin dull black, merging on to grey throat; rest of underparts pale olive, becoming whitish towards vent; iris whitish-grey (contrasting with dark face); bill strikingly greenish-yellow, palest on culmen and tip, mouth pink with brownish patches or variable yellow and pink; legs pale dusky orange-yellow, claws paler. Sexes alike. Juvenile is as adult, but head darker olive, yellow forehead duller, and underparts colder, duller green; iris probably darker and duller. Voice. Calls incessantly with shrill monosyllabic notes; vocalizations include thin, explosive, metallic, wheezy "jzhwink!", sometimes in long series, also a clearer, more jarring, chiming version, "chraink!".
Habitat. Usually confined to evergreen forest in areas receiving high rainfall; scarce in deciduous forest. Ventures into edge habitats, including bamboo, canebrakes, and *Lantana* scrub in abandoned clearings. Found at all levels of forest and in tall vine-laden shrubs. Likes similar habitat to that occupied by largely syntopic *P. gularis*, but generally prefers more humid areas with denser vegetation. From plains to 1200 m, rarely ascending higher, to 1800 m; commonest at 600–900 m.
Food and Feeding. Diet comprises berries and other fruit, including figs (*Ficus*), *Lantana* and *Ziziphus oenophila*; also a small proportion of insects. Forages at all levels of forest and in tall vine-laden shrubs; can be flighty, nervous and hard to see. Found singly and in pairs, sometimes in small groups of 4–8 individuals at fruiting trees or shrubs; often joins other frugivores such as fairy-bluebirds (*Irena*), orioles (*Oriolus*), etc.
Breeding. Breeds Mar–Jul. Nest a shallow cup, slight and flimsy, easily seen through from below, usually fastened with spider webs to branches of shrub, placed low down, 1–2 m above ground, but probably also sometimes higher in sapling or creeper; nest energetically defended by adults. Clutch 1–2 eggs. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Western Ghats EBA. Patchily distributed, but generally not uncommon in suitable habitat; common in the higher woods of Goa. Tends to be rare at lower altitudes, largely because most suitable habitat has been cleared, but in hilly regions extensive forest remains. Occurs in a range of protected areas, including Thattekad Bird Sanctuary, in Kerala, and Periyar Sanctuary, in Tamil Nadu. Many suitable forests (and several important protected areas) exist within Nilgiri Biosphere Reserve, and effective management and protection of this region would go a long way towards ensuring a secure future for this species.
Bibliography. Ali (1969, 1996), Ali & Ripley (1996), Barnes (1889), Betts (1929, 1931), Cardew (1895), Davison (1883), Dickinson *et al.* (2002b), Ferguson & Bourdillon (1903–1904), Fuller (1958), Grimmett *et al.* (1998), Kannan (1998), Lainer (1999), Rasmussen & Anderton (2005), Ripley (1982), Robertson & Jackson (1992), Saha & Dasgupta (1992), Sharpe (1882), Stattersfield *et al.* (1998), Sugathan & Varghese (1996), Wells (2005), Whistler & Kinnear (1932), Zacharias & Gaston (1993, 1999).

9. Black-headed Bulbul

Pycnonotus atriceps

French: Bulbul cap-nègre **German**: Schwarzkopfbülbül **Spanish**: Bulbul Cabecinegro

Taxonomy. *Turdus atriceps* Temminck, 1822, "Sandwich Islands"; error = Sumatra.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species previously placed in a separate genus *Brachypodius*; on basis of vocal, behavioural and morphological features, may merit return to this resurrected genus, alongside *P. priocephalus* and *P. fuscoflavescens*. Usually considered conspecific with last-mentioned, but considerable differences in plumage pattern and voice sufficient to warrant treatment as separate species. Forms described as *P. chalcocephalus* (Bantam district, in Java) and *P. cinereoventris* (Tippera district, in Bangladesh) shown to be variations of grey morph of present species, and "*Brachypodius immaculatus*" found to be a variant of the yellow type. Island races *hyperemnus*, *baweanus* and *hodiernus* poorly differentiated and in need of review. Proposed race *major* (NE India) was described on basis of inaccurate measurements and is invalid. Four subspecies provisionally recognized.
Subspecies and Distribution.
P. a. atriceps (Temminck, 1822) – E Bangladesh (Sylhet and Chittagongs), NE India (S of R Brahmaputra, to N Cachar and Manipur), Myanmar (except N) and S China (SW Yunnan) S to S Thailand, SW Cambodia, S Laos, S Vietnam, Peninsular Malaysia and Greater Sundas, and W Philippines (Calauit, Dumaran, Palawan).
P. a. hyperemnus (Oberholser, 1912) – W Sumatran islands (Simeulue, Nias, Mentawai Is).
P. a. baweanus (Finsch, 1901) – Bawean I (N of Java).
P. a. hodiernus (Bangs & J. L. Peters, 1927) – Maratua I (off E Borneo).

Descriptive notes. 16–18 cm; 20–30 g. Small, active, brightly coloured bulbul with very small legs. Whole head is black with metallic blue-green sheen; upperparts dark olive to yellow-olive, feathers of lower back and rump bright yellow with blackish bases (strongly barred effect when raised or ruffled), long uppertail-coverts bright yellow; rounded tail rich yellow at base and tip, broad black subterminal band; wings blackish, bright olive-yellow outer webs of secondaries and tertials forming large solid panel on inner wing, contrasting with black primaries (two-toned effect); breast and flanks dark olive to yellow-olive, rest of underparts bright yellow; plumage colour individually variable, some birds with greenish wash overall, others brighter yellow; iris pale cobalt-blue (often looks white at distance); bill black; legs brownish-black or dusky. Differs from *P. fuscoflavescens* in obviously black-hooded appearance, conspicuous two-toned wing, and darker subterminal tailbar. Rare grey morph has slaty neck, breast and belly, with vent, undertail-coverts and inner wing variably yellowish or white; in some areas (e.g. E Thailand) another morph occurs, with dull orange or yellow-green replacing yellow. Sexes alike. Juvenile is much duller, with less pronounced wing pattern, dark olive or brownish head and throat, yellow parts of plumage darker and greener, base of rump feathers brown; feathers of uppertail-coverts and undertail-coverts shorter, iris brownish or dull bluish-grey. Race *hyperemnus* is supposedly similar to nominate but with upperparts much darker, underparts slightly darker, bill stouter; *baweanus* differs in slightly larger size and longer tail (grey morph predominates); *hodiernus* is larger, with longer wing, grey-tipped tail, and lacks yellow tones in plumage. Voice. Flight call a single emphatic "tchimp" or "tchep"; similar calls when perched include distinctive, emphatic, downward-inflected "chew" or "chiw", often repeated irregularly every few seconds. Presumed song a similar, often lengthy, series of well-spaced very short, thin, sweet metallic "tink" notes that meander slightly in pitch and emphasis, the whole sequence somewhat disjointed and off-key, typically rising and then falling hesitantly; generally longer, lower and slower than that of *P. fuscoflavescens*. In India said to give melancholy double whistle (verification needed). Lacks boisterous vocalizations of typical members of genus.
Habitat. Broadleaf evergreen forest, mixed deciduous forest and peatswamp-forest, often where fairly open and at edges along roads, clearings, waterways, etc.; occurs also in second growth (at all stages of regeneration after disturbance), mature tree orchards and plantations in vicinity of natural habitat, bamboo, canebrakes, wooded gardens, scattered trees in *Imperata* grassland, back mangroves and well-developed coastal scrub. Often reaches peak density in lowlands, but in some regions commoner on lower slopes at 400–800 m; occasionally ascends to 1600 m, rarely higher (one record at 2450 m, another at 2580 m).
Food and Feeding. Fruits; some invertebrates. Figs (*Ficus*) feature prominently in diet, at Kuala Lompat (Peninsular Malaysia) include forest-edge banyans (*F. benjamina* or *F. microcarpa*), high-crown fruiting *F. glabella* and *F. sumatrana* and seven other species, with range of mean minimum diameter 5·4–14·8 mm; other recorded items include fruit of Rubiaceae, *Callicarpa pentandra* (Verbenaceae), *Clausena excavata* (Rutaceae), *Mallotus macrostachyus* and *Macaranga* (Euphorbiaceae), and *Trema orientalis* (Ulmaceae). Invertebrates taken include, among others, dragonflies (Odonata) and alate termites (Isoptera); two woodlice (Isopoda) found in one stomach, a grasshopper (Orthoptera) in another. Many insects (including dragonflies) and small fruit identified among food items delivered to nestlings. Ripe fruit picked from bushes and trees. Often reported as aerial-sallying for flying insects, often darts out, catches prey, and returns to same or nearby perch; also gleans small amount of invertebrate food from branches. Usually inconspicuous, but restless; in pairs or small parties moving through tall trees, often also in middle storey or lower at edges. Rarely, if ever, descends to ground (has very small legs). Sometimes visits fruiting or flowering shrubs and trees in scattered flocks containing up to 20 individuals (usually fewer than ten).
Breeding. Season Jan–Sept, usually Mar–Jun. Nests singly or in loose clumps of pairs, these clumps probably temporary and breeding not always synchronized, but one group of four pairs in Selangor (Malaysia) had full clutches of eggs simultaneously; one inter-nest distance measured 40 m. Nest a loosely constructed open cup, sometimes more compact and firmly made, in India described as made of tough creeper stems and twigs interwoven with few blades of coarse grass, often with outer layer of dead leaves, and lined with fine grass stems; in Thailand and Malaysia made of grass, creeper stems, plant fibres and much dead leaf material, and often lined with black fibres (possibly fungal hyphae); one in Borneo was of grass and vegetable fibres, another was built from dead twigs and other plant fibres; placed 1–6 m up (but usually low) in bush or tree, often in upright fork or cane fronds, recorded sites e.g. thorny bush and rhododendron (*Melastoma malabathricum*) in clearing, creepers and hanging vines, leaf axil of a ginger (Zingiberaceae), nodal branch tuft of bamboo, branch fork or main fork of forest sapling, similar fork in dense thicket of rubber (*Hevea*) saplings, outer-branch fork of plantation rubber, and in two instances exotic conifer planted at forest edge. Clutch 1–3 eggs, in Peninsular Malaysia usually 2; no information on incubation and fledging periods; both pair-members tend nestlings and fledglings; fledged broods of two in Malaysia.
Movements. Resident, but partially nomadic. Flocks roam and disperse over wide area in non-breeding season; rarely disappears entirely from a site, but paucity of recaptures suggests that many individuals are mobile. Seasonal altitudinal movements noted in some regions, e.g. NE India and N Bangladesh.
Status and Conservation. Not globally threatened. Locally common throughout much of range, tolerating fair degree of habitat degradation; very rare in S China and rare in India, with very few recent records. Grey morph was once locally fairly common in NE India, and remains regular in Java; it is commonest morph on Bawean I, and only morph on Maratua I. This species has been recorded in a large number of national parks, including Nam Bai 7at Tien (Vietnam), Khao Yai (Thailand), Taman Negara (Peninsular Malaysia), Kerinci-Seblat (Sumatra) and Ujung Kulon (Java).

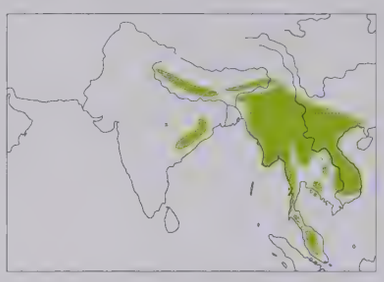
10. Andaman Bulbul

Pycnonotus fuscoflavescens

French: Bulbul des Andaman **German**: Andamanenbülbül **Spanish**: Bulbul de Andamán
Other common names: Andaman Black-headed Bulbul

Taxonomy. *Brachypodius fuscoflavescens* Hume, 1873, Port Mouat and Mount Harriet, South Andaman.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species previously placed in a separate genus *Brachypodius*; on basis of vocal, behavioural and morphological features, may merit return to this resurrected genus, alongside *P. priocephalus* and *P. atriceps*. Usually considered conspecific with last-mentioned, but considerable differences in plumage pattern and voice sufficient to warrant treatment as separate species. Monotypic.
Distribution. Andaman Is (South I and Middle I).



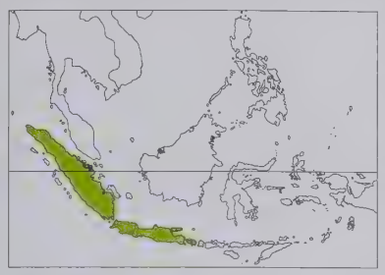
Descriptive notes. 14–17 cm. Small, active bulbul. Male has dull blackish forehead and throat usually with glossy greyish sheen, grading into dark olive crown and face; nape, mantle, back and scapulars dusky olive; rump feathers yellow at tip and black at base (vaguely barred effect where bases visible); tail olive-yellow at base with dark brown subterminal bar and yellow tips (tips broadest on lateral feathers); upperwing coverts olive-green; flight-feathers dark brown on inner webs, dull olive-green fringing on outer webs, including on primaries; below, bright yellow, especially on belly to undertail-coverts, suffused with olive on breast; iris pale cobalt-blue; bill blackish-grey, on some individuals plumbeous blue with upper mandible tipped and edged black, on others nearly all blackish but paler and bluish at base; legs blackish-grey. Differs from *P. atriceps* in much less obviously black-hooded appearance, more dusky upperparts, paler subterminal tailbar, wing lacking conspicuous two-toned effect. Female is slightly smaller than male, with paler olive-green head lacking sheen, more greenish-yellow underparts. Juvenile is like female but duller, more uniform olive-green, with paler bill, browner head, paler throat, and narrower, weaker yellow tail tip. VOICE. Song a brief high-pitched, quick series of very short, thin, metallic "tsit-tsut-tsit" notes that alternate in pitch; generally higher-pitched, more regular in pattern, and briefer and faster than that of *P. atriceps*. Calls include similar note given singly every few seconds, and shrill, upward-inflected, almost disyllabic "shrinkit!", much more metallic and hard than equivalent call of *P. atriceps*.
Habitat. Evergreen forest, light deciduous forest, edges and thick secondary growth. Of 15 recent sightings, 54% in evergreen forest, 14% in semi-evergreen and 32% in deciduous; thus, seems to have relatively broad niche weighted towards evergreen forest, in contrast to *P. jocosus* (of Andaman race *whistleri*), which sighted more frequently but never in evergreen forest.
Food and Feeding. Fruit, plucked from branches of trees and shrubs; probably also insects, but confirmation required. Usually encountered singly or in pairs, sometimes in small groups; often an inconspicuous component of understorey or mid-storey mixed-species flocks.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Not evaluated. Likely to qualify as restricted-range species, confined to Andaman Islands EBA. Has received little attention, as for long considered a race of *P. atriceps*; estimates of status vary from abundant through comparatively rare to decidedly rare. Thought to be locally common, particularly in and around Mount Harriet National Park. Review of status required, with the aim of clarifying population size, trends and conservation requirements.
Bibliography. Ali (1996), Ali & Ripley (1996), Ball (1873), Gee (1995), Grimmett *et al.* (1998), Hume (1873a, 1874), Osmaston (1906), Rasmussen & Anderton (2005), Ripley (1982), Stattersfield *et al.* (1998), Yoganand & Davidar (2000).

11. Black-crested Bulbul

Pycnonotus flaviventris

French: Bulbul à huppe noire **German**: Goldbrustbülbül **Spanish**: Bulbul Crestinegro
Other common names: Black-crested Yellow Bulbul, Black-headed Yellow Bulbul

Taxonomy. *Vanga Flaviventris* Tickell, 1833, Dampara, Orissa, India.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species previously placed, along with *P. dispar*, *P. gularis*, *P. melanicterus* and *P. montis*, in a separate genus *Rubigula*, to which all five may yet be returned. They form a superspecies, and have often been treated as conspecific under the name "*P. melanicterus*". Situation in SE Asia complicated by a tight clustering of races and the presence of different colour morphs; likely that some described races are insufficiently distinct to warrant recognition. Eight subspecies provisionally recognized.
Subspecies and Distribution.
P. f. flaviventris (Tickell, 1833) – N, NE & E India (Himalayan foothills E from Himachal Pradesh, S to to Meghalaya, also hills of Madhya Pradesh, also Eastern Ghats from Orissa S to Andhra Pradesh), Nepal, E Bangladesh, N, C & W Myanmar and S China (W Yunnan).
P. f. vantynei Deignan, 1948 –E & S Myanmar and NE & NW Thailand E to S China (S Yunnan, S Guangxi) and N Indochina.
P. f. xanthops Deignan 1948 – SE Myanmar (including N Tenasserim) and W Thailand.
P. f. auratus Deignan 1948 – NE Thailand and C Laos.
P. f. johnsoni (Gyldenstolpe, 1913) – C, NE & SE Thailand and S Indochina.
P. f. elbeli Deignan, 1954 – Gulf of Thailand islands (at least Ko Kut, Ko Chang).
P. f. negatus Deignan, 1954 – S Myanmar (C Tenasserim) and SW Thailand (valley of R Mae Klong).
P. f. caecilii Deignan, 1948 – extreme S Myanmar (S Tenasserim), SE & SW Thailand and N Peninsular Malaysia.
Introduced (race unknown) to Singapore.



Descriptive notes. 18·5–19·5 cm; male 30–34 g, female 28–31 g. Medium-sized, conspicuous bulbul with permanently erected recurved crest, squared long tail. Nominate race has head entirely glossy blue-black, bearing mid-crown tuft of elongated feathers forming recurved crest (c. 20 mm tall); upperparts dark golden olive-green, somewhat brighter on lower back and rump; wings and relatively plain tail browner (dusky olive) with bright golden-olive fringes; bright rich yellow below, suffused with olive on breast and flanks (a few individuals have underparts tinged orange); iris conspicuously creamy white or pale yellow; bill black; legs black, brownish-black or dark slate-grey. Sexes similar. Juvenile is paler overall, with sooty head and little or no crest (faint purplish gloss on longest crest feathers), chin black, throat olive (same colour as upperparts), iris pale grey. Races vary mainly in plumage tone, those around Gulf of Siam generally having shorter crest and more noticeable tinge of orange on breast than races from India and Myanmar: *vantynei* is darker than nominate, duller green upperparts almost lacking golden suffusion, underparts duller yellow (rare variant has variable amount of red on throat); *xanthops* is smaller than previous, upperparts much lighter and more golden (but darker, more greenish and less golden than nominate); *auratus* has somewhat darker and less golden upperparts than last (also, rare variant has variable amount of red on throat); *johnsoni* is similar to previous but smaller, with upperparts slightly darker and less suffused with golden (a colour morph occurring chiefly in Indochina has variable amount of red on throat); *caecilii* is similar to previous (black-throated form), but upperparts darker olive-green, almost without golden suffusion; *negatus* has upperparts lighter and more gold-suffused than last (seeming intermediate between that and *xanthops*); *elbeli* is duskier on chest and mantle, lacking golden suffusion found in adjacent forms. VOICE. Song recognizably bulbul-like but very sweet and musical, lacking harsh or guttural notes, whole phrase fairly simple, at first halting and then speeding up, each note staccato and distinct, becoming more emphatic and upward-inflected, e.g. "whik-whik, whirru weet!", "whit-whaet-ti-whaet" or "chu-chi-chu-chi-wit"; shorter versions include "whik, wiur". In Malaysia (race *caecilii*) similar, concise, strongly modulated phrases, as "pic tyu-wai" or "quill quee-ah", and shorter "wheet-siu".
Habitat. Open forest, mixed deciduous forest, abandoned clearings, tall hedgerows, orchards, edges of settlements, gardens; rarely in dense forest, and then only on top of canopy. In Nepal frequents lower altitudes, where dry dipterocarp forest is dominated by sal (*Shorea robusta*). In Thailand and Malaysia also inhabits landslips, roadsides, riverbanks, bamboo jungle, tree plantations e.g. rubber (*Hevea*), scattered tree cover in tea plantations, and patches of *Baeckia* heath-forest. Level lowlands, from sea coasts to c.1500 m, rarely to 2400 m; reported upper limit of 1970 m in Cameron Highlands (Peninsular Malaysia).
Food and Feeding. Feeds mainly on fruit, also small amount of insects. Fruit taken, and also fed to fledglings, includes small berries of e.g. *Eurycoma longifolia* (Simaroubaceae) and *Solanum xanthocarpum* (Solanaceae), and figs (e.g. *Ficus macrocarpa*, *F. glabella*, *F. sumatrana*). Found singly or in pairs, occasionally in small (family?) groups of up to six individuals, on shrubs or trees; sometimes noisy, but usually rather quiet and retiring for a bulbul. Seldom descends to ground, although has been seen to feed on ground on wild strawberries (*Fragaria*) in Myanmar. Less insectivorous than many bulbuls, but regularly hover-gleans insects from branches and leaves; less often, hawks flying insects, e.g. alate termites (Isoptera), from high perch.
Breeding. Season Mar–Sept (mainly May–Jun) in India, Mar–Apr in Myanmar and Jan–Aug in Peninsular Malaysia. Nest very neat and small for size of bird, outer walls composed of dead leaves (apparently often orange or yellow) interlaced by thick shreds of bark and elastic twigs, strengthened and bound by cobwebs, inner layer made of grass stems, fine twigs and fern roots, lined with fine fibres and soft moss strands; usually placed in low bush, 1–2 m up, or in creepers against tree or wall, less often in branches or upright fork of high bush or small to medium-sized tree e.g. citrus or mango (*Mangifera*), sometimes up to 9 m above ground; other sites include road-bank tangles of scrambling ferns and bamboo clumps. Clutch in Malaysia 2 eggs, in India and Myanmar 2–4 (usually 3); no information on incubation and fledging periods; both parents tend fledglings.
Movements. Resident. Was in past noted to roam in cold weather around Yangon (Myanmar), tending to leave forest and enter towns.
Status and Conservation. Not globally threatened. Generally common in much of range, including NE India, Bangladesh, Myanmar, S Laos, parts of Thailand and Peninsular Malaysia; rare in S China. Once common around Yangon, in Myanmar, but disappeared in early 1900s as a result of urbanization. Is generally favoured by deforestation, and therefore in no risk of extinction. Trapping for cagebird trade a problem in SE Asia, but this species appears resilient in the face of moderately intense pressure. A small introduced population in Singapore appears to be self-sustaining.
Bibliography. 12. Ruby-throated Bulbul

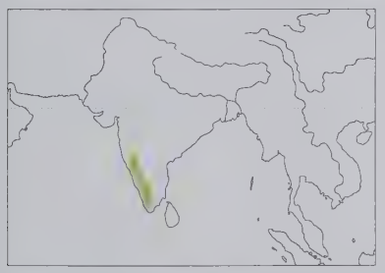
Pycnonotus dispar

French: Bulbul de la Sonde **German**: Sunda-Goldbrustbülbül **Spanish**: Bulbul Gorgirrojo

Taxonomy. *Turdus dispar* Horsfield, 1821, Java.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species previously placed, along with *P. flaviventris*, *P. gularis*, *P. melanicterus* and *P. montis*, in a separate genus *Rubigula*, to which all five may yet be returned. They form a superspecies, and have often been treated as conspecific under the name "*P. melanicterus*". Monotypic.
Distribution. Sumatra, Java and Bali.



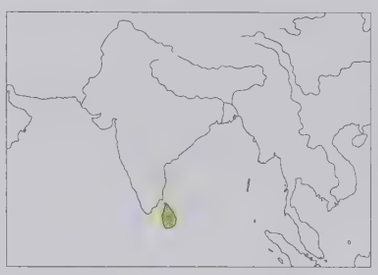
Descriptive notes. 17–20 cm. Medium-large, long-tailed, noisy, conspicuous bulbul. Has glossy black head, almost lacking crest; upperparts uniform olive-green; wings fringed brighter yellow-green on primaries and secondaries; tail dark brown, usually with pale tips of outer feathers; chin and throat feathers bright crimson, distinctly slim, elongated, stiffened and often flared; upper breast rich orange-yellow (a much deeper colour than *flaviventris*), rest of underparts yellow, suffused with orange, smudged greyer on flanks; iris bright fiery red; bill black, gape pink; legs brownish-black. Differs from *P. flaviventris* in e.g. much smaller crest, much deeper orange on breast. Sexes alike. Juvenile has dull yellow throat (red feathers quickly growing through), and duller, duskier breast; iris paler and duller. Voice. Calls transcribed as "tee-tee-wheet-wheet", "whit-wheet-wit" or "hii-tii-hii-tii-wiit", and various permutations of these elements; similar to *P. flaviventris*.
Habitat. Range of shrubby habitats and open woodland, including rubber (*Hevea*) plantations. Avoids tall forest, preferring even highly degraded areas, larger clearings, edges of towns, drier semi-deciduous forest, coastal woodland and back mangroves etc. To c. 1000 m.
Food and Feeding. Eats berries and other fruit, and small amounts of insects. No other information.
Breeding. Poorly known. Eggs found in Apr in Sumatra and Aug in C Java. Clutch 1–2 eggs. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to common; rare in Bali. In most of range still reasonably common in drier forests of lowlands, despite heavy degradation; common even in E & S Java, where heavily trapped for the cagebird trade. In view of trapping pressure, populations should be monitored. Occurs in several protected areas, including Kerinci-Seblat National Park, in Sumatra, and Ujung Kulon, Meru Betiri and Baluran National Parks, in Java.
Bibliography. van Balen (1999), Büttikofer (1887), Danielsen & Heegaard (1995), Deignan (1948b), Dickinson & Dekker (2002b), van Helvoort & Soetawijaya (1987), Hoogerwerf (1949b), Inskipp *et al.* (1996), MacKinnon (1988), MacKinnon & Phillipps (1993), MacKinnon *et al.* (2000), van Marle & Voous (1988), Sargeant (1997), Tobias & Phelps (1994).

13. **Flame-throated Bulbul**

Pycnonotus gularis

French: Bulbul à gorge rubis **German**: Kerala-Goldbrustbülbül **Spanish**: Bulbul Gorginaranja
Other common names: Ruby-throated(!)/Orange-throated Bulbul, Ruby-throated Yellow Bulbul

Taxonomy. *Brachypus gularis* Gould, 1836, Travancore [= Kerala], India.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species previously placed, along with *P. flaviventris*, *P. dispar*, *P. melanicterus* and *P. montis*, in a separate genus *Rubigula*, to which all five may yet be returned. They form a superspecies, and have often been treated as conspecific under the name "*P. melanicterus*". Monotypic.
Distribution. Western Ghats S from Goa, in SW India.



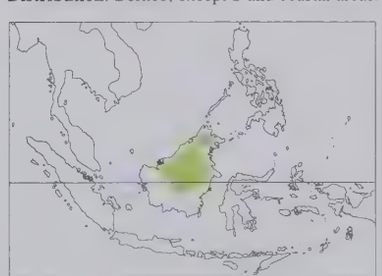
Descriptive notes. 18–19 cm. A slim, noisy, relatively inconspicuous bulbul with very short, ragged occipital crest, relatively short, very slightly rounded tail. Head, including crest, is glossy black; upperparts yellowish-olive-green, wings browner with golden-olive fringes; tail bright olive, small creamy-white tips at corners; deep flame-coloured orange throat patch (looks dark at distance or in poor light), breast orange-yellow with only a little olive mixed in, rest of underparts bright yellow; iris pale yellow (contrasting with black head); bill black; legs dusky grey-green to blackish-grey or horny brown. Sexes alike. Juvenile has brownish-black head, yellow throat. Voice. Song a sweet, hurried, very musical, rather high-pitched stuttering but emphatic series, e.g. "pr'r'r'rit, tir'r, r'r'rit, tir'r r'rit", each note rising steeply; rather different from that of *P. flaviventris*. Frequent calls include subdued, upslurred churring "prririt" notes like initial notes of song phrase, or clear short rising "prit" notes.
Habitat. Evergreen foothill forest, especially in lower-edge ecotone with drier formations, in thorny bamboo brakes, and riverine shrubbery. Fond of abandoned clearings overgrown with secondary forest and well-developed thickets of *Lantana* and *Mimosa*; avoids active cultivation. From plains to 900 m, rarely to 1200 m.
Food and Feeding. Feeds on figs (*Ficus*) and other fruit, and insects. Often in small flocks, which seem to keep more to dense cover; much less conspicuous than *P. flaviventris*.
Breeding. Season Jan–Aug, mainly Feb–Apr. Nest a small neat cup of dead leaves (often yellow or orange), bound lightly with cobweb and broad grass stems, skimpy lining of finer grass, usually 1–3 m above ground in bush. Usual clutch 2 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally uncommon, but locally fairly common (e.g. in S Kanara). Relatively scarce in N of range, but thought still to be common in Goa; generally scarce and local in S. Unlikely to be in imminent danger, as it is not restricted to intact forest and tolerates quite heavily degraded habitats. A sizeable population occurs in Periyar Sanctuary. Many suitable forests (and several important protected areas) are found within the Nilgiri Biosphere Reserve, and effective protection and management of this region would go a long way towards ensuring a secure future for this species.
Bibliography. Ali (1969, 1996), Ali & Ripley (1996), Barnes (1889), Betts (1929, 1931), Butler (1881), Davison (1883), Dickinson & Dekker (2002b), Dickinson *et al.* (2002b), Fairbank (1877), Ferguson & Bourdillon (1903–1904), Grimmett *et al.* (1998), Kannan (1998), Lainer (1999), Rasmussen & Anderton (2005), Ripley (1982), Robertson & Jackson (1992), Saha & Dasgupta (1992), Strange (2002), Walden (1866), Whistler & Kinnear (1932), Zacharias & Gaston (1999).

14. **Black-capped Bulbul**

Pycnonotus melanicterus

French: Bulbul à tête noire **German**: Sri Lanka-Goldbrustbülbül **Spanish**: Bulbul Carinegro
Other common names: Black-capped Yellow Bulbul, Black-headed Yellow Bulbul

Taxonomy. [*Muscicapa*] *melanictera* J. F. Gmelin, 1789, Sri Lanka.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species forms a superspecies with *P. flaviventris*, *P. dispar*, *P. gularis* and *P. montis*, and all five usually treated as conspecific. All may merit placement in a separate genus, *Rubigula*. Present species is the most distinct member of the superspecies owing to its short rounded tail with broad white tips, but its other characters (lack of crest, yellow throat, dark iris) are mirrored independently by distant Bornean *P. montis*. Monotypic.
Distribution. Sri Lanka.



Descriptive notes. 18–19 cm. Medium-sized, noisy, conspicuous bulbul with strongly rounded tail, half of basal portion of which covered by elongated uppertail-coverts and undertail-coverts; essentially uncrested (slender filaments protrude from nape). Head is intense, unglossed black, upperparts dusky olive-green, yellowest on rump; wings and tail browner, flight-feathers and rectrices with bright olive-yellow fringes, outer tail feathers with broad white tips, narrow tips on central pair; rich saffron-yellow below, breast lightly clouded with olive; iris light brown to red (partly age-related); bill black; legs dark pinkish-grey to blackish. Sexes alike in plumage, female said to have duller iris. Juvenile is dark brown on mid-crown and nape, has duller iris than adult. Voice. Broad repertoire of sweet, mellow, minor-key piping whistles and sharper calls. Staccato, jerky-sounding song sounds like "cherkit-cherkit, chink-ut, chink-ut", first 2 notes low and subdued, others alternating and ending lowest. Other vocalizations include series of short, quavering, rising and then falling notes, "puwit puwit puwit-wit-wit"; quavering, gradually rising mellow "pu'u-pu'u-pu'u-pu-Wit!"; low, mellow, plaintive whistles, singly or in pairs (with second note slightly higher and louder than first); occasionally, similar-toned "dut, tud-durt" or a series of subdued, slightly guttural "prrt, prrt, prrt". Calls also include hard, rapid whipcrack notes in short series, sometimes combined with short mellow whistles.
Habitat. Open woodland, second growth at various stages of regeneration, luxuriant forest, gallery forest, forest edge and adjacent gardens; prefers broken, patchy forest to intact forest. Level lowlands and low hills of wet and intermediate zones, to at least 1200 m.
Food and Feeding. Thought to be mainly insectivorous; also eats small berries and seeds. Snails and minute ammonites have been found in stomachs of specimens. A confiding, active species, almost always in pairs, sometimes in small (family?) groups of 3–4 individuals; sometimes associates with *P. luteolus* and *Acritillas indica*. Often makes hovering sallies for insects.
Breeding. Breeds Mar–Sept; probably double-brooded. Nest a small flimsy cup, usually loosely constructed, made of fine roots, grass, creeper tendrils, and small twigs, interlaced with dead leaves, bound with spider webs, lined with fine grasses, placed 1–3 m above ground among dense foliage, often in upright fork of bush close to the ground, or even on stump; one nest was slung hammock-like between branches of a horizontal fork, but this seems to be unusual. Normal clutch 2–3 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally common, one of the commonest forest birds in Sri Lanka. Generally absent from arid sector, but occurs in several protected areas, including Peak Wilderness Sanctuary.
Bibliography. 15. **Bornean Bulbul**

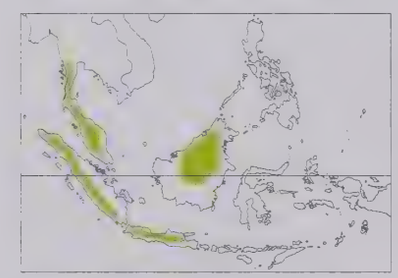
Pycnonotus montis

French: Bulbul de Bornéo **German**: Borneo-Goldbrustbülbül **Spanish**: Bulbul de Borneo

Taxonomy. *Rubigula montis* Sharpe, 1879, Kinabalu, north Borneo.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species forms a superspecies with *P. flaviventris*, *P. dispar*, *P. gularis* and *P. melanicterus*, and all five usually treated as conspecific. All may merit placement in a separate genus, *Rubigula*. Monotypic.
Distribution. Borneo, except S and coastal areas.

Descriptive notes. 17–18 cm. Medium-small, active, conspicuous bulbul with slightly elongated crest feathers (raised when bird excited). Head is dull black, upperparts dull olive; wings and tail browner, with yellow-olive fringing; throat whitish-yellow, merging into bright olive-yellow underparts, yellower on belly and vent (less yellow than *P. melanicterus*); iris dark red-brown (whitish under lid); bill fairly slender, black; legs dark grey. Sexes alike. Juvenile undescribed, probably duller and browner then adult and with dull iris. Voice. Constantly given sharp "yek, yek". Song said to resemble that of *P. melanicterus*.



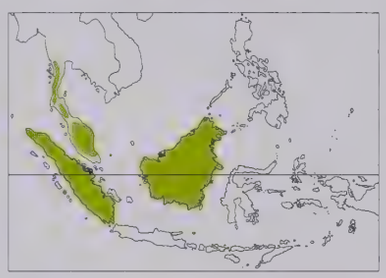
Habitat. Evergreen forest, secondary forest, and shrubby regrowth on abandoned cultivation; 600–1500 m.
Food and Feeding. An arboreal frugivore and partial insectivore. Eats fruit of *Macaranga* (Euphorbiaceae) less than 4 mm in diameter, also *Trema orientalis* and *T. tomentosa* (Ulmaceae), *Litsea* (Lauraceae); berries generally swallowed whole, but one individual seen to squeeze small black seeds from watery flesh of capsules of *Homolanthus* (Euphorbiaceae). Often perches in open at forest edges. Regularly performs aerial sallies to capture flying insects.
Breeding. Little known. Nest with 2 fresh eggs found at 1200 m in late Jan; nest a deep cup of dry stems and leaves, similar to that of *P. goiavier* but looser. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Not evaluated. Seems relatively scarce in E Bornean highland forest (particularly around Gunung Kinabalu), but more common and conspicuous in other areas; locally abundant in Trusan and Kelabit Highlands. Likely to be secure, given its reliance on mid-altitude degraded forest.
Bibliography. Amadon & Harrisson (1957), van Balen & Nurwatha (1997), Dickinson *et al.* (2002b), Jenkins *et al.* (1996), MacKinnon & Phillipps (1993), Smythies (1957, 1999), Strange (2002), Wilkinson, Dutson, Sheldon *et al.* (1991).

16. Scaly-breasted Bulbul

Pycnonotus squamatus

French: Bulbul écaillé **German**: Schuppenbülbül **Spanish**: Bulbul Escamoso

Taxonomy. *Ixos squamatus* Temminck, 1828, Java.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. This species was previously placed with *P. cyaniventris* in a separate genus *Ixidia*; given the strong morphological, behavioural and vocal differences from "typical" members of current genus (i.e. the "*P. capensis* complex" and the "*P. cafer* complex"), may be better returned to former genus or placed in resurrected *Brachypodius*. Name of race *webberi* sometimes emended to *weberi*, which tallies with name of collector; as current spelling appears in type description and has never been formally corrected, however, it should be retained. Three subspecies recognized.
Subspecies and Distribution.
P. s. webberi (Hume, 1879) – extreme S Myanamar (extreme S Tenasserim), S Thailand, Peninsular Malaysia (including Langkawi) and Sumatra.
P. s. squamatus (Temminck, 1828) – Java.
P. s. borneensis Chasen, 1941 – Borneo.



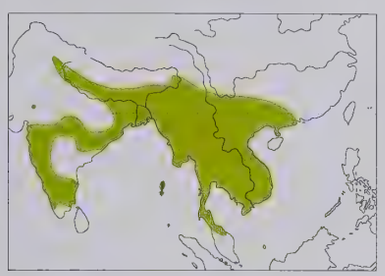
Descriptive notes. 14–16 cm ; 19–23 g (*webberi*), 22–24 g (*borneensis*). Small, quiet, strikingly patterned bulbul with relatively slender bill. Nominate race has lores, cheeks, ear-coverts, crown and nape solid black, contrasting sharply with pure white throat; mantle dusky olive, greener on rump; wings dark brown with bright olive fringing; tail black, conspicuous white tips of all except central pair of rectrices; white of throat sharply demarcated from breast and flanks, which are black with conspicuous white fringes, producing distinctive scaled effect (pattern and density of breast markings individually variable); belly whitish, undertail-coverts bright yellow; iris crimson or ochre (yellow or orange-yellow in some birds, presumably related to age or sex); bill black; legs black. Sexes alike, male perhaps on average darker. Juvenile (only recently described, from a single field observation in Peninsular Malaysia) similar to adult, but with black of upper breast smudgy, lower breast whiter, eyes duller. Race *webberi* has upperparts darker and more olivaceous than nominate, outer tail feathers with larger white tips, lower abdomen more prominently scaled, greyish flanks with less prominent scaling; *borneensis* differs from previous in slightly smaller size (although published weights on average heavier), upperparts more bronze-green and less olive-green, and uppertail-coverts more golden, less yellowish-green. Voice. Calls frequently while foraging, with a series of sharp high-pitched "wit" or "tit" notes. Only other vocalizations noted are thin, cheeping "tree", persistent "trrip, trip" and a "pretty trill", repeated at intervals at different pitches. These descriptions perhaps amount to basically the same sound.
Habitat. Broadleaf evergreen forest, either mature or disturbed, but with tall cover remaining or well regenerated; has also been recorded in quite low secondary growth, including bamboo jungle, well clear of original forest. Sometimes at plains level, but generally scarce in level lowlands, and more common in hilly country between 500 m and 1000 m; highest elevational record at 1400 m (Peninsular Malaysia).
Food and Feeding. Frugivorous, apparently also insectivorous. Feeds on wide variety of berries and other small fruits, including figs (*Ficus*), *Trema orientalis* (Ulmaceae), *Callicarpa candicans* (Verbenaceae); figs identified in diet include banyans (*F. benjamina* or *F. microcarpa*), *F. virens*, *F. glabella* and *F. sumatrana*. Small bill suggests that this species targets fruit in smaller size-classes. Usually found in canopy or high edges, either singly or in small independent groups, less often accompanying canopy flocks. In one study at Gombak, in Peninsular Malaysia, was noted in 20 of 80 mixed flocks; usually, however, it moved independently of flocks and joined them only temporarily. One exceptional report of 150 at a single fruiting tree, but gatherings of this size seem unlikely. Able to hover briefly, but only evidence of interest in animal prey is the regular attendance of mixed-species foraging flocks in canopy. Seen to drink and bathe at forest streams in Sumatra.
Breeding. Poorly known. One dependent fledgling in Peninsular Malaysia on 21st Jul. Nest undescribed; probably builds in canopy or subcanopy. Reported clutch contained 2 eggs. No other information.
Movements. None reported, but fluctuating numbers at sites suggest some form of movement, local or otherwise.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Widespread and locally fairly common in foothill forest, a habitat under less pressure than lowland forest in its range; seems to be particularly scarce and patchily distributed in Borneo. The catastrophic clearance of primary forest in Sundaic region must be causing drastic declines in this species' population, but its occurrence on submontane slopes (where forest cover remains extensive) suggests that it is under no immediate threat of extinction. Occurs in several important protected areas, including Hala-Bala Wildlife Sanctuary, in Thailand, Kerinci-Seblat National Park, in Sumatra, and Mount Kinabalu National Park, in Borneo.
Bibliography. van Balen (1999), Büttikofer (1887), Chasen & Hoogerwerf (1941), Collar *et al.* (2001), Davison (1987, 1997b), Davison & Chew Yen Fook (1996), Dickinson & Dekker (2002b), Dickinson *et al.* (2002b), Gibson-Hill (1949), Gregory-Smith (1997a), Holmes (1996, 1997), Jenkins *et al.* (1996), Jeyarajasingam & Pearson (1999), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Phillipps (1993), Madoc (1976), van Marle & Voous (1988), McClure (1966, 1967), Medway & Wells (1976), Mitra & Sheldon (1993), Rheindt (2004), Riley (1938), Robson (2000, 2004), Smythies (1957, 1986, 1999), Stattersfield & Capper (2000), Wells (2005).

17. Grey-bellied Bulbul

Pycnonotus cyaniventris

French: Bulbul à ventre gris **German**: Graubauchbülbül **Spanish**: Bulbul Ventrigrís

Taxonomy. *P[ycnonotus]. ? cyaniventris* Blyth, 1842, Singapore.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. This species was previously placed with *P. squamatus* in a separate genus *Ixidia*; given the strong morphological, behavioural and vocal differences from "typical" members of current genus (i.e. the "*P. capensis* complex" and the "*P. cafer* complex"), may be better returned to former genus or placed in resurrected *Brachypodius*. The names "*aureum*" and "*poliopsis*" are junior synonyms of nominate race. Two subspecies recognized.
Subspecies and Distribution.
P. c. cyaniventris Blyth 1842 – extreme S Myanmar (S Tenasserim), S Thailand, Peninsular Malaysia and Sumatra (including Sipura I).
P. c. paroticalis (Sharpe, 1878) – Borneo.



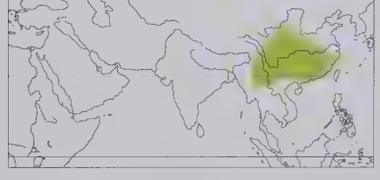
Descriptive notes. 16–17 cm; 19–24 g. Medium-small, relatively quiet, inconspicuous bulbul. Male nominate race has blackish lores, contrasting with pale grey supraloral line; rest of head to neck slaty blue-grey, mantle to uppertail-coverts bright golden-olive; wings blackish-brown with bright yellow-olive fringing (brighter and yellower than rest of upperparts); tail dark brown with dull olive fringing (no black or yellow); chin, throat and most of underparts slaty blue-grey, centre of belly white, undertail-coverts chrome-yellow, thighs sooty olive, underwing-coverts yellow; iris blue-grey, dark chocolate-brown or slaty grey-brown (age-related or sex-related?); bill blackish-horn; legs black or slaty grey, claws horn-brown, sometimes almost black. Female is slightly paler grey and duller yellow. Juvenile undescribed, but birds with pale brown or brownish-grey irides presumed to be immature. Race *paroticalis* is somewhat larger than nominate, also slightly brighter, especially on wing-coverts, which have bright golden-yellow margins, pale superciliary streak more conspicuous, partly because cheeks and ear-coverts are blacker. Voice. Clear sweet notes given in series of up to 9, sounding like "pi-pi-pwi..., pi-pi-pwi-pwi..." etc., similar to those made by minivets (*Pericrocotus*); subdued "wit wit wit" contact calls, and slightly descending bubbling, trilled whistle, "pi-pi-pi-pi-pi-pi-pi", also heard; another infrequently given call is distinctive "clewk".
Habitat. Broadleaf evergreen forest, mature, well regenerated or with much tall timber left standing after disturbance; often found at forest edges beside clearings, roads and rivers. Usually avoids plantations or any other non-native tree habitats. Occurs in level lowlands, but usually commoner in hilly country from 400 m upwards; recorded upper limit of 1070 m in Peninsular Malaysia.
Food and Feeding. Frugivore; said to be partial insectivore, and attendance of mixed-species flocks suggests that this is the case, but no direct observations of insects being taken. Eats fruits of tall evergreen trees, including *Macaranga*, *Trema orientalis*, rhododendrons (e.g. *Melastoma malabathricum*), figs (*Ficus*, including *F. benjamina*, *F. microcarpa*, *F. glabella*, *F. sumatrana*), euphorbs (e.g. *Mallotus* cf. *paniculatus*). In study at at Kuala Lompat, in Peninsular Malaysia, visited twelve of 25 bird-eaten *Ficus* species, all of them with mean minimum fruit diameter in range 5·4–15·5 mm. Two fledglings in Peninsular Malaysia were fed with fruits of the introduced shrub *Clidemia hirta*. Loners less usual than are pairs or small, typically single-figure parties. Usually keeps to tree canopy, often accompanying *P. squamatus*, or mixed-species flocks of insectivores, sunbirds (Aegithalidae) and flowerpeckers (Dicaeidae); regularly visits berry-laden trees along with other frugivores, especially barbets (of genus *Megalaima*). One patch of fruiting riverside banyans was visited by a party that returned on approximately 90-minute cycle. Seems more dextrous and active than most bulbuls, frequently hanging in manner of a tit (Paridae) to reach berries, and changing perch often.
Breeding. Usually breeds Dec–Mar; eggs found in late Jan, dependent fledglings mid-May in Peninsular Malaysia; also Aug and Nov in Borneo. Cup-shaped nest built from dead grass, moss and other plant material, usually placed low down in vegetation, once among leaves caught on suspended liana 4 m up in disturbed forest. Usual clutch 2–3 eggs; no information on incubation and fledging periods; both pair-members tend fledglings, fledged broods of two reported.
Movements. None reported, but likely to be mobile (as most other frugivorous forest-based members of genus).
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Locally fairly common or common throughout much of range, particularly Peninsular Malaysia and Sumatra; rare in S tip of Myanmar, at least historically, and generally uncommon in Borneo. The catastrophic clearance of lowland primary forest in Sundaic region is presumably causing drastic declines in the population of this species, but its occurrence on submontane slopes suggests that it is under no immediate threat of extinction. Has been recorded in variety of protected areas, including Hala-Bala Wildlife Sanctuary, in Thailand, Kerinci-Seblat National Park, in Sumatra, and Kutai and Tanjung Puting National Parks, in Borneo (Kalimantan).
Bibliography. Büttikofer (1887), Collar *et al.* (2001), Danielsen & Heegaard (1995), Davison (1987), Dickinson *et al.* (2002b), Duckworth & Kelsh (1998), Duckworth *et al.* (1996), Gibson-Hill (1949), Glenister (1971), Holmes (1994, 1997), Hose (1893), Hume & Davison (1878), Jeyarajasingam & Pearson (1999), Lambert (1989b), Lekagul & Round (1991), MacKinnon & Phillipps (1993), Madoc (1976), van Marle & Voous (1988), McClure (1966), Medway & Wells (1976), Nash & Nash (1988), Riley (1938), Robson (1991a, 2000), Smythies (1957, 1986, 1999), Stattersfield & Capper (2000), Thompson (1966), Vowles & Vowles (1997), Wells (1990b, 2005).

18. Red-whiskered Bulbul

Pycnonotus jocosus

French: Bulbul orphée **German**: Rotohrbülbül **Spanish**: Bulbul Orfeo

Taxonomy. [*Lanius*] *jocosus* Linnaeus, 1758, Guangzhou, Guangdong, south China.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species may merit placement in a separate genus, *Otocompsa* (currently a subgenus). S China race *hainanensis* was initially assumed to relate to escaped cagebirds (there is no wild population on Hainan). Described Indian races *provincialis* (Uttar Pradesh) and *erythrotis* (West Bengal), and *peguensis* (from Myanmar), considered insufficiently distinct to justify recognition; thus, the first is merged with *pyrrhotis* and the last two with *emeria*. Racial identity of Laos population uncertain, tentatively included in *pattani*. Nine subspecies recognized.
Subspecies and Distribution.
P. j. abuensis (Whistler, 1931) – NW India (W Rajasthan, N Maharashtra, but absent from more arid areas).
P. j. fuscicaudatus (Gould, 1866) – W & C India.
P. j. pyrrhotis (Bonaparte, 1850) – N India (Punjab E to Arunachal Pradesh) and Nepal.
P. j. emeria (Linnaeus, 1758) – E India (Ganges Delta S to Rameswaram, in Tamil Nadu), Bangladesh, N, W & S Myanmar (including Arakan Hills) and SW Thailand.
P. j. whistleri Deignan, 1948 – Andaman Is.
P. j. monticola (Horsfield, 1840) – E Himalayas in NE India and S Tibet E to N Myanmar and S China (W & S Yunnan).
P. j. pattani Deignan, 1948 – extreme S Myanmar (S Tenasserim), Thailand, N Peninsular Malaysia, Laos and S Indochina.
P. j. hainanensis (Hachisuka, 1939) – N Vietnam and S China (S Guangdong, including Nao Chow Tao).
P. j. jocosus (Linneaus, 1758) – SE China (Guizhou E to Guangxi, E Guangdong and Hong Kong). Introduced (races unknown) in E Saudi Arabia, United Arab Emirates, Oman, Mauritius, Nicobar Is, Malaysia (Kuala Lumpur, Melaka and Penang), Singapore, Borneo (Brunei), E Australia, Hawaii (Oahu) and SE USA (Florida).



Descriptive notes. 18–20·5 cm; 25–31 g. Slim, dark-backed, conspicuous bulbul with long crest, which often held upright. Nominate race has black crown and crest, bright red spot behind eye ("ear-tuft"), white ear-coverts, cheek and throat, fine black moustachial line; upperparts, wings and tail dull brown, all tail feathers except two central pairs tipped white; underparts whitish, washed brownish on sides, broad black pectoral band variably complete (usually broken), undertail-coverts red; iris brown or dark brown; bill black; legs and claws black. Sexes similar. Juvenile has shorter, browner crest, red postocular tuft replaced by white, paler brown upperparts, much weaker breastband, undertail-coverts suffused with pink, and vent dull buffish-pink to yellowish or orange. Race *fuscicaudatus* has breastband complete, lacks white tips on lateral tail feathers; *abuensis* is similar to previous but paler overall, with breastband incomplete; *pyrrhotis* has all tail tips white, breastband incomplete, upperparts pale brown; *emeria* has upperparts bright warm brown, crest very long, bill slim; *whistleri* is similar to last but slightly smaller, with crest shorter and bill larger; *monticola* is darker and more saturated overall, with flanks and lower abdomen smoky buff, ear-tufts small and deep crimson (composed of more rigid and wiry feathers), dark breastband complete; *pattani* has upperparts cold greyish-brown, ear-tufts short and dark red, white tips of tail feathers conspicuous; *hainanensis* has flanks, lower and upper abdomen, breast and lower throat smoky buff, ear-tufts small and rather dark. Voice. Song short and spirited, often second main note highest and loudest, thereafter descending in pitch; similar in pattern to that of *P. cafer* but much more rich and complex, lacking harsh or guttural notes; longer songs rise and fall twice, "wit-ti-waet, queep kwil-ya, queek-kay". Calls include first 2 notes of the song, e.g. "queee-kwut", and other song fragments; also short harsh raspy "bzeep", sometimes introducing song. Anxious, querulous, musical "pr'r" or "per'r'p" also heard, usually during extended communal period prior to roosting.
Habitat. Wide range of habitats, including dense hilly woodland, secondary scrub, roadsides, parkland, orchards, reedbeds, urban and suburban gardens and parks; found also in cultivation, ranging from slash-and-burn clearings in secondary forest to totally open sugar-cane plantation. Absent from intact forest, and commonest near humans. In India, generally confined to wetter, more evergreen areas than those utilized by *P. leucogenys* and *P. cafer*. In most of range occurs commonly up to 1000 m, and regularly to c. 2000 m; in Peninsular Malaysia restricted to lowland plains, including up to landward edge of coastal mangroves.
Food and Feeding. Generalist and opportunist; feeds on fruit (fond of *Lantana* berries), nectar, flower buds, and invertebrates; around habitations, takes kitchen waste and visits birdtables. Observed to harvest fruit of figs (*Ficus*), *Macaranga* (Euphorbiaceae), *Muntingia calabura*, and arils of *Acacia mangium* seeds. Visits the flowers of *Careya arborea* (a tree flowering in dry season in Eastern Ghats) to feed on nectar; also collects nectar from *Erythrina* (Fabaceae) and *Spathodea campanulata* (Bignoniaceae). Individuals reported also as eating flowers (e.g. of *Tabernaemontana divaricata*). Takes many arthropods, notably caterpillars, but also grasshoppers (Orthoptera), beetles (Coleoptera), arachnids etc.; sometimes hawks alate termites (Isoptera) and moths (Lepidoptera). Young nestlings tend to be fed with soft-bodied insects and larvae, with more drupes and berries as they become a little older. Usually encountered singly, in pairs or in small, family-sized parties; outside breeding season larger foraging parties form (regularly up to 30 individuals, rarely 100). Communal roosts of over 1000 reported in Myanmar. Most foraging takes place in trees and bushes, but descends fairly often to ground, where it shuffles about on short legs to pick up seeds and ants etc. Often jaunty, with flight oddly slow and jerky.
Breeding. In India, breeds Mar–Oct in N and variably throughout year (mostly Dec–May) in S; Apr–May in Andamans and N Thailand; Feb–Jul in Peninsular Malaysia. Male (and possibly female) displays by lowering head, drooping and quivering wings, and slowly raising and lowering fanned tail. Nest a fairly deep, compact, substantial open cup composed of twigs, leaves (including leaf skeletons and bamboo leaves), dry grasses, creeper stems and flakes of bark, bound together with cobwebs, inner cup usually lined with fine hair-like rootlets (e.g. of the climbing fern *Drymoglossum heterophyllum*), coconut fibres, thin grass and mammalian hair, with dead leaves and dried ferns worked into base, man-made items such as pieces of cloth and paper often incorporated (in nests in villages), external dimensions 10 cm across and 7·5 cm deep, internal dimensions 5·6–6·4 cm × 3·8 cm; usually placed 1–3 m (0–4·5 m) above ground (average height exceeding that of *P. cafer* and *P. aurigaster*) in branch fork of bush, thorny shrub, hedge or tree, including rubber (*Hevea*), *Saracca* and *Lagerstroemia*, but sometimes virtually on ground, also in dense-foliaged exotic conifer, bamboo, or creepers against tree, wall or garden lattice, sometimes in odd situation such as on verandah, in basket, within building, roof thatching or stack of straw, or even down well, and once (Andamans) in mangrove by water. Clutch 2–4 eggs, usually 3; incubation may start with first egg, but intermittent (and only diurnal) until clutch complete, incubation period 12–14 days, hatching sometimes asynchronous; nestlings tended by both pair-members, fledging period unrecorded in wild, maximum 14 days in captivity; both parents also tend fledglings, for recorded maximum of 34 days, juveniles stayed together for further 13 days. Heavy predation on nests reported.
Movements. Essentially resident over much of range, but subject to apparently unpredictable invasive or irruptive movements (sometimes in loose flocks containing hundreds of individuals), and curiously patchy in local distribution and habitat occupancy. Roosts communally in non-breeding season.
Status and Conservation. Not globally threatened. Common in many regions. Abundant in S & W India, and common (at least historically) in NE India; very common in Hong Kong, where possibly introduced (was absent or rare in 1800s, increasing through 1900s); common in Bangladesh; previously common in S Myanmar (current status unknown); common in rural Laos; fairly common in S China. Common in many parts of its non-native range; e.g. in Nicobars has become abundant, replacing sparrows (*Passer*) as the bird of towns and buildings, and possibly outcompeting the endemic pycnonotid (*Ixos nicobariensis*) such that the latter is now threatened. Because it is commensal with man, benefits from clearance of forest and is tolerant of heavily degraded habitat. In SE Asia, however, this species is increasingly threatened by hunting and trapping, and in Thailand and N Peninsular Malaysia has been extirpated over large tracts of land in which it was formerly very common; until recently remained common in N Thailand, but recent dramatic declines reported, possibly following an upsurge in popularity of singing contests, and concomitant trapping of birds for this use. Programmes promoting awareness are required, and monitoring schemes needed to track shifts in status. This species is considered an agricultural pest in some regions, where it frequently damages ripening crops (e.g. peas) or buds in fruit orchards.
Bibliography. 19. Brown-breasted Bulbul

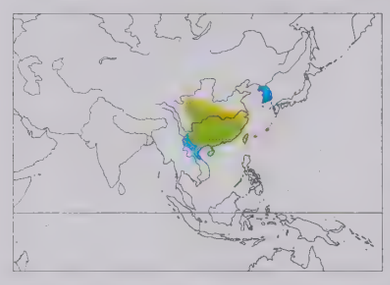
Pycnonotus xanthorrhous

French: Bulbul à poitrine brune **German**: Braunbrustbülbül **Spanish**: Bulbul Pechipardo
Other common names: Anderson's Bulbul

Taxonomy. *Pycnonotus xanthorrhous* Anderson, 1869, Manyun, near Lienshan, west Yunnan, China.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species perhaps merits placement in a separate genus, *Otocompsa* (currently a subgenus). Validity of race *andersoni* questionable, as its purported characters (shade of plumage, extent of breastband) are to large extent due to wear, fading and specimen preparation; intergrades said to occur where it overlaps with nominate in S China (N & SE Yunnan). Two subspecies provisionally recognized.
Subspecies and Distribution.
P. x. andersoni (Swinhoe, 1870) – C & S China (SE Gansu, Sichuan and N Yunnan E to S Jiangsu, Zhejiang, Jiangxi and Fujian, S to N Guangdong).
P. x. xanthorrhous Anderson, 1869 – SE Tibet, S China (SE Sichuan, Guizhou and SW Hunan S to S Yunnan and the Yao Shan, in Guangxi), N & E Myanmar (including Ruby Mines district and Southern Shan States), NE Thailand, N Laos and N Vietnam (W Tonkin).

Descriptive notes. 20 cm; 24–31 g. Medium-large, noisy, conspicuous bulbul. Crown to below eyes, nape, lores and moustachial streak are black; minute blood-coloured spot at base of lower mandible; ear-coverts, hindneck, neck side in front of wing bend, and mantle to uppertail-coverts soft greyish-brown; wings and tail darker greyish-brown, lightly margined brownish-olive, tail feathers with narrow white tips (often lost through abrasion); chin, throat, lower breast and belly white, contrasting with sharply defined brown breastband, narrower at centre; flanks and lower belly slightly sullied with pale greyish-brown; undertail-coverts deep yellow or orange-yellow; iris brown to dark brown; bill black; legs dark brown to blackish. Sexes alike. Juvenile is somewhat duller, with less distinct breastband, browner head markings, paler upperparts. Race *andersoni* lacks or virtually lacks breastband, and is marginally paler. Voice. Song a repeated quick simple "chirriwu'i whi'chu whirri'ui" etc. Calls with harsh "chi" or "brzzp" notes and thinner "ti-whi".
Habitat. Secondary growth, scrub, tall grass, gardens, thickets, clearings and streamside vegetation in montane zone. Fond of bramble (*Rubus*) and bracken-covered hillsides, often with scattered trees, but usually fairly open; in Myanmar and N Thailand replaced by *P. flavescens* in denser or taller vegetation. Usually at 1000–2300 m, sometimes as low as 600 m, and recorded up to 4275 m in S China (N Yunnan).
Food and Feeding. Fruit, also seeds, and insects. Individuals in Myanmar seen to pluck fruit from variety of plants, including *Heptapleurum* (Araliaceae), "carmine cherry" and wild raspberry (*Rubus*).
Breeding. Season Apr–Aug, mainly May–Jun. Builds typical cup-shaped nest, usually fairly loose but sometimes more compact, usually c.1 m up in low vegetation, e.g. in brambles, among grass and weeds, or in bracken (Dennstaedtiaceae). Clutch 2–4 eggs, usually 2. No other information.



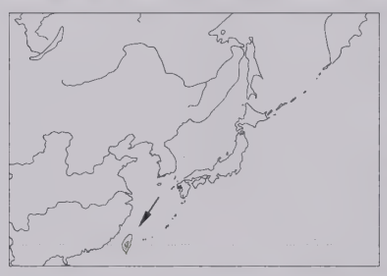
Movements. Resident; possibly shifts downslope during winter, at least in harsh conditions.
Status and Conservation. Not globally threatened. Locally common across a broad range. Abounds in agricultural landscapes in S China (e.g. Guizhou), and is fairly common in much of Myanmar (e.g. Bhamo district, Ruby Mines). Tolerates highly degraded habitats.
Bibliography. Caldwell & Caldwell (1931), Cheng Tsohsin (1987), Davidson (1998), Dickinson *et al.* (2002b), Duckworth, Salter & Khounboline (1999), Étchécopar & Hüe (1983), Harington (1905, 1909a), Lekagul & Round (1991), Lewthwaite (1996), MacKinnon & Phillipps (2000), Meyer de Schauensee (1984), Nguyen Cu *et al.* (2000), Oates (1895), Pershouse (1916), Rippon (1896), Robson (2000), Rothschild (1921), Smythies (1986), Stanford & Mayr (1940–1941), Traylor (1967), Yen (1934), Zhang Cizu *et al.* (1997), Zheng Guangmei & Zhang Cizu (2002).

20. **Light-vented Bulbul**

Pycnonotus sinensis

French: Bulbul de Chine **German**: Chinabülbül **Spanish**: Bulbul Chino
Other common names: Chinese Bulbul

Taxonomy. [*Muscicapa*] *sinensis* J. F.Gmelin, 1789, Guangzhou, Guangdong, south China.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species perhaps merits placement in a separate genus, *Otocompsa* (currently a subgenus). Closely related to, and often interbreeds with, *P. taivanus*; latter probably arose from an early colonization of Taiwan by present species, with contact between the two forms resumed after a secondary invasion. As nominate race and *hainanus* both occur on Hainan, some authors have treated these as separate species; their breeding ranges, however, do not overlap. Putative race *kobayashii* (Ishigakijima, in S Ryukyu Is) is indistinguishable from *orii*; *hoyi* (middle Yangtze Valley) was described from a juvenile specimen, and is a junior synonym of nominate. Four subspecies recognized.
Subspecies and Distribution.
P. s. sinensis (J. F. Gmelin, 1789) – C & E China (Sichuan and S Shaanxi E to mouth of R Yangtze, S through Guangxi, Guangdong and Fujian; also isolated sites in Beijing and Hebei); non-breeding N & C Vietnam, Hainan and South Korea.
P. s. hainanus (Swinhoe, 1870) – SE China (Hainan, SE Guangdong) and N Vietnam; non-breeding S to C Vietnam.
P. s. formosae Hartert, 1910 – Taiwan (excluding S & E coast S of Taroko Gorge).
P. s. orii Nagamichi Kuroda 1923 – S Ryukyu Archipelago (Okinawa, Yaeyama Is).



Descriptive notes. 19 cm. Medium-sized, noisy, conspicuous bulbul. Nominate race has striking head pattern, with black crown and moustachial stripe, broad white postocular stripes meeting to form band on upper nape (band narrower after post-nuptial moult, gradually widening with abrasion), white patch at rear of otherwise dark ear-coverts, white throat; upperparts greyish-brown, admixed with dull olive on mantle; wings and tail dark grey-brown, fringed with bright olive, outer tail feathers with narrow whitish fringe at tips; underparts whitish, pale grey-brown breastband (vaguely mottled), yellowish-grey belly and yellowish-white undertail-coverts (both indistinctly streaked darker); iris deep brown to blackish; bill black; legs black. Sexes similar. Juvenile has paler upperparts, entire head pale greyish-brown, breastband less distinct, wings and tail paler and duller, iris paler and greyer. Race *hainanus* lacks pale band from eye to nape, pale ear-covert spot smaller; *formosae* has white band on nape, relatively uniform and slightly greyer upperparts, darker grey breastband, and whiter rest of underparts with fewer, fainter yellow streaks; *orii* is similar to nominate, but has shorter wing, darker band on chest. Voice. Typical bulbul sounds in a range of cheerful phrases and strikingly peculiar notes, difficult to transcribe; calls frequently with loud "tocc-tocc-tocc". Groups said to produce low chattering, with individuals occasionally ascending to tops of bushes to give louder calls.
Habitat. Cultivation, borders of cultivation, orchards, gardens with large shrubs, scrub and open woodland; to 500 m.
Food and Feeding. Eats variety of berries, small figs (*Ficus*), soft fruit and vegetables; also insects, e.g. dipteran flies, sometimes caught in aerial pursuit. Often perches prominently on bushtops; gathers in large flocks in winter. Foraging behaviour generally poorly known.
Breeding. Breeds Apr–Jun, sometimes as late as Oct; multi-brooded, often 3–4 nests per season. Nest a firm cup-shaped structure, usually constructed from broad grasses, lined with finer grass and rootlets, variety of other materials (including scraps of cotton, paper, cloth, leaves, leaf skeletons, flowers and feathers) sometimes incorporated, nests in Taiwan reported as made largely of swordgrass (*Brachiaria decumbens*) flower spikes (with down still attached), leaves and bamboo leaves and lined with stripped swordgrass flower spikes; usually placed 1–3 m, occasionally at least 6 m, above ground in upright fork of bush, hedge or creeper, sometimes between intersecting branches of bamboo, at times in close proximity to man, e.g. nest found in honeysuckle (Loranthaceae) on sixth-floor verandah in Hong Kong apartment block. Clutch 3–4 eggs, rarely 5; no information on incubation and fledging periods.
Movements. Largely resident; migratory in N. Post-breeding movement S by N populations, with regular records in Hebei and on Shandong Peninsula. Large influx of nominate race in Hong Kong in non-breeding season; this race also recorded in flocks of up to 80 birds in winter in C Vietnam (along with smaller numbers of *hainanus*), and small numbers reach N Laos; a few winter in South Korea, where first record at Eocheong I (Jeollabuk Province) in Oct 2002. Race *hainanus* a winter vagrant in N Thailand and C Laos.
Status and Conservation. Not globally threatened. One of the commonest birds in S China, especially in cultivated and settled areas; abundant in many regions, including Hong Kong and also in parts of Taiwan. Being commensal with man, this species requires no conservation action; it is favoured by deforestation and tolerant of highly degraded habitats. For this reason, its range is spreading: first recorded in Beidaihe, Hebei, in autumn 1986, it has subsequently become established there as a breeding species; colonized S Japan (Ryukyus) in 1900s, and now a common breeding resident in the region. Also a common winter visitor in N Indochina. Causes some damage to garden crops (tomatoes, peas and others) in China, and to other commercial crops in Okinawa, in S Japan.

(1978), Swinhoe (1863), Traylor (1967), Webster (1975), Wilkinson (1929), Yamasaki (2002), Yan Anhou (1985), Zhang Cizu *et al.* (1997), Zheng Guangmei & Zhang Cizu (2002).

21. **Styan's Bulbul**

Pycnonotus taivanus

French: Bulbul de Taiwan **German**: Taiwanbülbül **Spanish**: Bulbul de Taiwan
Other common names: Taiwan/Formosa Bulbul

Taxonomy. *Pycnonotus taivanus* Styan, 1893, Taiwan.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species perhaps merits placement in a separate genus, *Otocompsa* (currently a subgenus). Closely related to, and often interbreeds with, *P. sinensis*; probably arose from an early colonization of Taiwan by that species, with contact between the two forms resumed after a secondary invasion by it. Monotypic.
Distribution. E coast of Taiwan S of Taroko Gorge (including Hengchun Peninsula).

Descriptive notes. 19 cm. Medium-sized, conspicuous bulbul with stout bill. Has cap and moustachial streak black, small orange-red spot at base of lower mandible; lores and ear-coverts silvery buff; hindneck light brown, mantle dull ashy brown, lightly washed with olive; wings and tail dark brown, outer webs of remiges and rectrices fringed bright olive-yellow; buffish-white below, flanks and thighs washed with ashy brown, undertail-coverts white, edged olive; iris dark brown; bill black; legs dark brown. Sexes alike. Juvenile undescribed. Voice. Variety of vocalizations typical of genus, including short choppy cheerful strophes; also more continuous chattering, especially when in groups.
Habitat. Second growth, farms and developed areas in coastal lowlands.
Food and Feeding. Diet consists of fruit and flowers. Singly or in pairs when breeding, but forms large flocks in non-breeding season.
Breeding. Reported in Mar–Jul; at least two broods annually. Nest, built by female, a cup-shaped structure placed 0·8–5 m above ground in bush, or in low tree such as crabapple (*Malus*). Clutch 3–4 eggs, mean 3·3; incubation by female, period 11–12 days; male assists with provisioning of young, nestlings fledge 9–10 days after hatching.
Movements. Resident.
Status and Conservation. VULNERABLE. Restricted-range species: present in Taiwan EBA. Still common in many areas, but potentially threatened by hybridization with *P. sinensis*; hybrid pairs quite common in areas of contact, and produce viable offspring. Historical records reveal that the vast Ilan Plains in NE Taiwan were once occupied by present species; it has since disappeared from this area, and its range continues to contract in the face of competition with *P. sinensis*. It remains common in Kenting National Park, in S Taiwan, and part of this area should perhaps be established as a refuge for the species; active elimination of *P. sinensis* from such a refuge may prove necessary if its expansion continues. The range and population status of both species on Taiwan need to be closely monitored.

22. Common Bulbul

Pycnonotus barbatus

French: Bulbul des jardins **German**: Graubülbül **Spanish**: Bulbul Naranjero
Other common names: Black-eyed/Black-capped Bulbul, Common Garden Bulbul; Somali Bulbul (*somaliensis*); Dodson's Bulbul, (African) White-eared Bulbul (*dodsoni*); Dark-capped/Yellow-vented(!)/Tricoloured Bulbul (*tricolor*); Egyptian Bulbul (*arsinoe*)

Taxonomy. *Turdus barbatus* Desfontaines, 1789, "Côtes de Barbarie" = near Algiers, Algeria.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species forms a superspecies with *P. nigricans*, *P. capensis*, *P. xanthopygos*, *P. leucotis* and *P. leucogenys*, possibly including some other species. Hybridizes extensively with first two of these in narrow transition zones along at least part of boundaries between their respective distributions; old record of a mixed pair of present species and *P. xanthopygos*, but no hybrids known (and ranges apparently do not meet). Races *tricolor*, *dodsoni* and *somaliensis* sometimes treated as separate species on basis of plumage differences (colour of head and undertail-coverts, presence or absence of white patch on neck side, and plain or mottled breast pattern), but intermediates known in many cases. The whole complex merits further study. Races *gabonensis* and *inornatus* intergrade in Nigeria; described races *nigeriae* (S Nigeria) and *goodi* (N Cameroon) not satisfactorily distinguishable from former and latter respectively. In addition, a number of other described races are too poorly marked to warrant recognition: thus, *minor* (upper White Nile and Bahr el Ghazal), *fayi* (Kenyan Highlands) and *ngamii* (L Ngami, in Botswana) merged with *tricolor*, *micrus* (SE Kenya) and *tenebrior* (Eastern Cape, in South Africa) with *layardi*, and *peasei* (Kitunga, in Kenya) with *dodsoni*. Ten subspecies recognized.
Subspecies and Distribution.
P. b. barbatus (Desfontaines, 1789) – Morocco E to Tunisia.
P. b. inornatus (Fraser, 1843) – S Mauritania and Senegal E to N Niger (Aïr), NW & W Chad, N Nigeria and N Cameroon.
P. b. gabonensis Sharpe, 1871 – C & S Nigeria and C Cameroon S to Gabon and S PRCongo.
P. b. tricolor (Hartlaub, 1862) – E Cameroon E to S Sudan, W & C Kenya and S to Angola, NW Botswana and N & W Zambia.
P. b. arsinoe (M. H. K. Lichtenstein, 1823) – Egypt (Nile Valley), Sudan (S to S Kordofan) and E Chad.
P. b. schoanus Neumann, 1905 – highlands of Eritrea and Ethiopia (S to NW Sidamo-Borama, E to Dire-Dawa and Harar) and extreme SE Sudan.
P. b. somaliensis Reichenow, 1905 – Djibouti, NW Somalia and SE Ethiopia (NE Bale, SE Arussi).
P. b. spurius Reichenow, 1905 – S Ethiopia (S Bale S to N Sidamo-Borama).
P. b. dodsoni Sharpe, 1895 – NC Somalia and E parts of lowland Ethiopia S to S Kenya (Chyulus, Tsavo).
P. b. layardi J. H. Gurney, Sr, 1879 – SE Kenya (Taveta) and E Tanzania (including Zanzibar) S to E & S Zambia, NE Botswana and E South Africa.

Descriptive notes. 15–20 cm; male 34–49·5 g, female 29–42 g (*layardi*). Conspicuous bulbul with slightly peaked crown, giving distinctive head shape. Nominate race has top of head, cheeks and ear-coverts dark brown, faint white spot (whitish feather bases) sometimes present on hind margin of ear-coverts; lores and feathering around eye blackish; upperparts dark grey-brown, often slightly paler on rump; wings as upperparts or slightly darker; tail black, some browner tinges on central pair of feathers and outer webs of other pairs; throat dark brown, becoming paler on to body, upper breast dark brownish-grey, lower breast and flanks paler brownish-grey, becoming dull grey on belly; undertail-coverts white, some feathers with indistinct greyish shaft streaks and yellowish margins; in worn plumage, face becomes browner, upperparts duller and more grey, breast somewhat browner, belly more whitish-grey, edges of tail and flight-feathers bleached; iris red-brown, brown or dark brown; bill black or blackish-horn; legs black, blackish-horn or brownish-horn. Sexes alike, female on average smaller. Juvenile is as adult, but face duller grey-brown, upperparts somewhat paler, undertail-coverts entirely white; feathering, particularly on rump and undertail-coverts, softer and looser. Race *inornatus* is similar to nominate, but underparts greyer, some faint paler edging on breast feathers, belly whiter, undertail-coverts white or cream; *arsinoe* has blackish head and throat, brown breast sharply demarcated from white belly, breast feathers with pale fringes, undertail-coverts white; *schoanus* is similar to previous, but upperparts rather darker, head blacker, pale ear-covert patch smaller or absent, breast darker; *spurius* resembles last, but undertail-coverts deep yellow; *somaliensis* is also similar but somewhat paler, with white ear-covert spot larger and more conspicuous, pale edges of breast feathers more pronounced (mottled appearance where brown of breast meets white of belly); *dodsoni* is like last but with yellow undertail-coverts, breast spotting more developed (reaching upper belly), tail feathers pale-tipped, also upperparts somewhat scaly-looking (pale feather tips); *gabonensis* is like nominate, but head and upperparts darker, breast darker and sharply demarcated from white belly, undertail-coverts white with varying amounts of yellow (N populations paler, S ones more yellow); *tricolor* resembles previous, but undertail-coverts bright yellow; *layardi* is similar to last, but crown, face and chin black, contrasting with greyish-brown upperparts. Voice. Song loud and deliberate, consisting of sequentially repeated phrases, each of 3–7 somewhat abrupt and disjointed notes, e.g. "wee! wee-hoo-hoo", "quick-chop-toquick", "chuk-chuk-twirlup" and "chip-chop-chip-kweeko" (sometimes transliterated as "quick, quick, doctor, quick!"), total duration 0·8–2 seconds, intervals between phrases 1–10 seconds but generally 3–6 seconds; fine structure of phrases infinitely variable across species' range, but individuals possess repertoire of 2–9 phrases and each phrase is shared by 1–25 males; repertoire variation between among territorial males highly structured locally, such that neighbours have similar repertoires but birds over 3 km apart share no phrases. Soft, swizzling chatter by birds in resting state. Contact calls consist of rapid jumble of 3–5 notes, the first generally high-pitched; when anxious a nasal "chirrik" or "jerdut", which escalates to loud, shrill alarm, e.g. "kik-kik-kik" (like machine-gun noise), when scolding a predator, often ending in "crescendo" call similar to contact. Chattering "cheedle-cheedle-cheedletit" during wing-flicking display by male in conflict situation, or as greeting call to female; pair-members often greet with short burst of soft chatter.
Habitat. Almost any wooded or bushy habitat with sufficient abundance of fruiting trees or shrubs; absent only from unbroken forest or woodland, open grassland with no bushes, and treeless desert. Particularly fond of riverine habitats, penetrating desert, forest and woodland along streams. Occupies forest edges, temporarily entering canopy of old secondary forest and primary forest when attracted by fruiting trees; particularly common where forest fragmented for human settlement and in first stages of regeneration, such as overgrown areas with *Musanga* and thickets of Solanaceae. Penetrates forested areas along logging roads; colonizes isolated clearings and camps within a few years of creation. Sparse or absent in virgin stands of *Brachystegia*, *Baikiaea* and mopane (*Colophospermum mopane*) woodland, but tolerates more open areas where other bushes present. At high altitude occurs in bamboo thicket, juniper (*Juniperus*) woods (Ethiopia), bracken-briar (Malawi) and dense *Leucosidea* scrub (South Africa). In all types of wooded savanna and parkland, thickets and scrub, including (N Africa) *macchia*. Enters semi-arid areas along wadis and streams, colonizes oases, palm groves and wells in Sahara. Lives in swamp-forest, also papyrus swamps with *Miscanthidium* and other marsh plants; recorded even in pure papyrus several kilometres from lakeshore. Found in plantations of introduced timber trees, and especially common in orchards, gardens, fallows and scrubby vegetation around human settlement. Sea-level to 1100 m in Egypt, to 1650 m in Liberia, 2300 m in Morocco, 2350 m in Malawi, 2500 m in Sudan (Jebel Marra), and at least 3000 m in Ethiopia and E Africa.
Food and Feeding. Mostly fruit, also arthropods, nectar, flowers and some seeds; a few small vertebrates. Eats almost any fruit available. In N Africa, fruit taken includes *Arbutus*, *Balanites*, *Elaeaginus*, *Ficus*, *Jasminum*, *Olea*, *Nerium*, *Pistacia*, *Ziziphus* and apricots, citrus, dates, pomegranates; more than 50 species recorded in single study in Zimbabwe, where *Ficus* particularly favoured, also *Boscia*, *Commiphora*, *Cucumis*, *Erythrococca*, *Lantana*, *Morinda*, *Musanga*, *Melia*, *Rapania*, *Rauwolfia*, *Solanum* (up to 13 mm in diameter), *Trema*, as well as apple, wild asparagus, avocado, guava, mango, oil palm, papaya, banana, peach, pear, plum etc.; in study in Malawi, 21 species of wild fruit (diameter 3–15 mm) taken, principal genera *Afrocrania*, *Bridelia*, *Croton*, *Cussonia*, *Ficus*, *Harungana*, *Ilex*, *Macaranga*, *Maesa*, *Myrica*, *Polyscias*, *Prunus*, *Rauwolfia*, *Sapium*, *Syzygium*, *Trema* and *Viscum*. Flower parts eaten include *Acacia*, *Aloe*, *Calothamnus*, *Celtis*, *Eucalyptus*, *Grevillea*, *Pinus*, *Prosopis* and *Protea*; nectar taken from *Aloe* and *Greyia*, and young leaves from *Acacia* and *Prosopis*. Arthropods include alate termites (Isoptera) and ants (Hymenoptera), also aphids (Homoptera), beetles (Coleoptera), butterflies and moths (Lepidoptera), dragonflies (Odonata), grasshoppers (Orthoptera), mantids, mayflies (Ephemeroptera), spiders (Araneae). Small vertebrates include small lizards and geckoes. Also takes beeswax. In study in Kenya, diet 72% fruit, 14% flowers, 14% insects. Nestling diet entirely insects for first week, subsequently augmented with fruit. Forages in pairs, in family parties of 3–4 individuals, or in large groups with other frugivores; may gather into larger, loose flocks of up to 100 birds during non-breeding season. Feeds in trees and shrubs; food occasionally taken from ground. Plucks berries and swallows them whole, sometimes hanging-upside down from twigs, and pecks into larger fruits; takes fallen fruit. Probes flowers, particularly aloes, for nectar. Gleans arthropods from foliage, sometimes while hovering, and darts after insects flushed by its activity; often sallies after flying insects, twisting and turning in pursuit of prey, regularly returning to same perch on top of tree or bush, or moving to new perch. In early morning will glean insects from walls and similar substrates (where insects attracted by lights on previous evening). Breaks open termite galleries to take workers, and attends swarms of *Dorylus* ants. Accepts food at feeders, picnic sites and camping grounds, and forages on buildings for spiders and nocturnal insects. Drinks regularly, being dependent on nearby water during the dry season.
Breeding. Season Mar–Sept (mainly May–Jul) in Morocco, May–Aug in Algeria and Tunisia, and Mar–Aug in Egypt; probably all year in W Africa, peaks variable, e.g. Feb–Apr in N Mauritania and Jul and Dec in S, mainly Jun–Aug in Senegambia, Aug–Feb in Liberia, mainly Jul–Dec in Ghana but mainly during Apr–Jul rains in Nigeria; mainly Jan–Oct in NE, but to Dec in E Ethiopia (*dodsoni*); all months in C & E Africa, peak Sept–Nov in Angola; Jul–Apr (peak Sept–Nov) in Zambia, Sept–Feb (peak Oct–Nov) in Malawi, and Aug–Mar (mainly Sept–Dec/Jan) in Zimbabwe and Botswana; Sept–Apr in South Africa; at least some females double-brooded. Monogamous. Solitary nester, territorial only during breeding season, male sings almost continuously from prominent perches for 30–40 minutes at dawn, irregularly and for shorter bouts through rest of day. Courting male gives characteristic wing-flutter display accompanied by whining calls. Nest built by female, taking 8–10 days, a neat and strong, but often thin-walled cup of dry grass, rootlets and small twigs, lined with finer plant fibres, animal hair, and sometimes human fabrics, external diameter 7·5–12 cm and depth 5–6 cm, internal diameter 6–7 cm and depth 4–5 cm; placed on branch or twigs, or slung between twigs in fork, and attached to support with spider webs, usually 1–5 m (occasionally up to 13 m) above ground and generally far from trunk of supporting tree; often nests close to human activity, usually screened by vegetation but occasionally in open. Clutch 2–5 eggs, laying interval 1 day (rarely 2 days); incubation by female, starting when clutch complete, fed on nest by male, incubation period 12–15 days; chicks fed by both parents, often visiting together, nestling period 10–17 days, mostly 13–16 days; young can barely fly when they leave nest, remain bunched together in nearby foliage for first few days before starting to follow adults, start to feed themselves at 28–33 days, but usually fed until 40 days and may continue to beg until 50 days. Of 13 eggs in Morocco, ten hatched and five young fledged, and in Gabon mean of 0·82 young fledged from 64 nests (42% of nests lost, all to driver ants); nesting success 22% in South Africa (111 nests) and 40% in Zimbabwe (98 nests), and average of 2·3 young fledge per successful nest in S Africa. Brood parasitism by Jacobin Cuckoo (*Clamator jacobinus*) frequent, with occasional parasitism by African Emerald, Klaas's and Diederik Cuckoos (*Chrysococcyx cupreus*, *C. klaas* and *C. caprius*) and Red-chested Cuckoo (*Cuculus solitarius*); other causes of loss include young falling from small nests, nests washed away by heavy rain, and predation by shrikes (Laniidae), mongooses (Herpestinae) and cats.
Movements. Resident across much of range. In N Africa may wander locally, mostly within breeding range, particularly in winter, and in Senegambia leaves most arid parts in dry season. Also, influxes with the rains reported in parts of the Sahel in Chad.
Status and Conservation. Not globally threatened. Common to abundant across its huge range; one of commonest birds in Africa. Population in Liberia estimated to be at least 1·5 million pairs, and in S Mozambique 5–10 million birds. Estimated densities in Morocco 1·6 pairs/km² in undisturbed woodland, 14·8 pairs/km² in degraded woodland, and 21–24 pairs/km² in semi-arid scrub in lowlands and high valleys; in Swaziland 69 birds/100 ha in acacia (*Acacia*) savanna, 79 birds/100 ha in broadleaf woodland and 345 birds/100 ha in riverine forest; breeding densities of 10 pairs/100 ha in mixed *Brachystegia* woodland in Zimbabwe and up to 14 pairs/100 ha in suburban

gardens in South Africa (Eastern Cape). Has thrived in certain anthropogenic habitats; has, for example, benefited from forest fragmentation and the afforestation of grasslands, particularly around human settlements. Range in Egypt expanded considerably during 20th century. Well represented in a large number of protected areas across its range. Sometimes killed as a pest in fruit orchards.
Bibliography. 23. African Red-eyed Bulbul

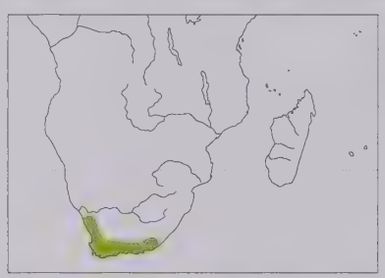
Pycnonotus nigricans

French: Bulbul brunoir **German**: Maskenbülbül **Spanish**: Bulbul Encapuchado
Other common names: Black-fronted/Red-eyed Bulbul

Taxonomy. *Turdus nigricans* Vieillot, 1818, banks of the Orange River in Namaqualand, Namibia–South Africa border.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species forms a superspecies with *P. barbatus*, *P. capensis*, *P. xanthopygos*, *P. leucotis* and *P. leucogenys*, possibly including some other species. Parapatric and locally sympatric with both *P. barbatus* and *P. capensis*, and hybridizes extensively with both in narrow transition zones along at least part of boundaries between their respective distributions. Nominate race intergrades with *superior* over a broad front along middle R Orange and in Griqualand West (South Africa). Proposed race *grisescentior* indistinguishable from nominate. Two subspecies recognized.
Subspecies and Distribution.
P. n. nigricans (Vieillot, 1818) – SW Angola, Namibia and Botswana S to N South Africa (S to Northern Cape and middle R Orange); non-breeding extreme SW Zambia and NW Zimbabwe.
P. n. superior Clancey, 1959 – South Africa (North-west Province S to Eastern Cape) and Lesotho.



Descriptive notes. 19–21 cm; 21·5–37·5 g. A medium-sized bulbul with slightly peaked crown, giving distinctive, squarish head shape. Has head and neck black, ring of bare orange or orange-red skin around eye; upperparts, including wings, grey-brown, some feathers with paler margins; tail blackish-brown, very narrow pale tips (which disappear through abrasion); chin and throat blackish-brown, side of neck and breast brown, feathers with pale fringes producing scaly appearance, lower breast whitish with some narrow brown streaking, flanks pale brown, belly white, vent and undertail-coverts bright yellow; iris bright red to orange; bill black; legs black. Differs from very similar *P. barbatus* and *P. capensis* in conspicuous orange-red eyering. Sexes alike, female on average slightly smaller than male. Juvenile is like adult, but duller and paler above, eyering pink, eye brown; newly fledged young have no coloured eyering, by 2 months acquire yellowish-white ring, which gradually changes to pink by 3 months. Race *superior* in on average larger than nominate, slightly darker above, and blackish-brown of throat extends farther on to breast, which is more extensively brown. Voice. Loud song of repeated phrases, each of up to c. 7 notes, given generally only by male in the wild (both sexes apparently sing in captivity); very like that of *P. barbatus*, but delivered more slowly and with notes tending to be a little richer and deeper. Contact call a fast jumble of c. 3–5 notes, also various chattering and nasal calls; loud chattering call of 2–3 seconds by male during wing-flicking display, in conflict situations or as greeting to mate; all calls extremely similar to those of *P. barbatus*.
Habitat. Dry woodland, acacia (*Acacia*) savanna, semi-arid shrubland, riverine bush, and shrubby watercourses in otherwise open and treeless areas; also orchards and gardens. Replaces *P. barbatus* and *P. capensis* in wide range of habitats in arid and semi-arid regions, wherever water and sufficient trees or shrubs present. Distribution corresponds with lower winter temperatures and higher coefficient of variation in annual rainfall of arid interior. Lowlands from sea-level, to 2000 m in W Lesotho.
Food and Feeding. Large range of wild and cultivated fruits; also arthropods and nectar. Fruits taken include, among others, figs (*Ficus*), *Lantana*, *Popowia*, mulberry, grapes. Arthropods mostly insects, such as beetles (Coleoptera), ants (Hymenoptera) and aphids (Homoptera). In captivity, average daily consumption (dry weight) c. 22% of the bird's own weight. Usually found in pairs or small, loose groups; larger foraging flocks during non-breeding season, when regularly joins mixed-species parties. Noisy and conspicuous, with continuous, excited calling from large groups gathered at fruiting trees. Forages, sometimes acrobatically, in trees and shrubs; occasionally on ground. Flies up to hawk insects above vegetation, and darts after insects flushed from foliage. Visits feeders and birdbaths in gardens, where it becomes tame and familiar. Drinks regularly.
Breeding. Recorded mainly in Oct–Dec in Botswana, Nov–Jan in South Africa and Dec–Feb in Namibia, and is stimulated by first rains of spring. Monogamous. Solitary nester, adjacent pairs at least 50–100 m apart; territorial during breeding season, male sings during dawn chorus from several prominent perches. Courting male gives characteristic wing-flutter display accompanied by whining call. In wild, nest built by only one partner, presumably female, whereas both sexes of a captive pair recorded as building; nest is a cup of dry grass, fine twigs, rootlets and other fibres, lined with finer grass fibres, external diameter 9–12 cm, depth 7 cm, inner diameter 6–6·5 cm, depth 4·5–5 cm; placed in fork in bush or tree, often well hidden, at height of 1–4 m. Clutch 2–3 eggs, rarely 4, laid at 1-day intervals; incubation by female only, period 11·5 days; for one pair in captivity, incubation by both sexes, period 12 days; chicks fed by both parents, nestling period 12–13 days; fledglings able to feed themselves at 26 days, but still accept food from parents. Average of 2·2 young fledge per successful nest. Brood parasitism by Jacobin Cuckoo (*Clamator jacobinus*) regular.
Movements. Wanders during dry non-breeding season. In addition, parts of some populations undertake often wide-ranging movements E of normal range in dry season or during drought years. Seasonal influxes of large numbers into the Okavango Delta (N Botswana) and as far N as R Zambezi and SW Zambia commonly occur. Nearly all records in NW Zimbabwe are during dry season, indicating seasonal movement from Botswana; Zambian records from early Jun to late Oct. During droughts, moves down Limpopo Valley and into NE Gauteng and C Northern Province, in South Africa; regular but temporary influxes into Kalahari Gemsbok National Park and parts of the arid C Karoo in Northern Cape correspond with high rainfall events or with fruiting seasons of trees and shrubs. One unusual record of a pair on Cape Peninsula, 250 km from SW limit of species' normal range.
Status and Conservation. Not globally threatened. Common and widely distributed. Thrives in gardens and orchards, and has benefited from the provisioning of water for stock animals in arid areas. Well represented in protected areas.
Bibliography. Benson *et al.* (1971), Brewster (1991), Britton (1972), Clancey (1964), Dean & Bond (1994), Dean (2000), Dowsett & Forbes-Watson (1993), Dowsett & Dowsett-Lemaire (1993), Everitt (1964b), Ginn *et al.* (1989), Hall & Moreau (1970), Harrison *et al.* (1997), Herremans & Herremans (1995), Irwin (1981), Keith *et al.* (1992), Lawson (1962), Liversidge (1970), Lloyd (2005a), Lloyd & Palmer (1998), Lloyd, Craig *et al.* (1997), Lloyd, Hulley & Craig (1996), Mackworth-Praed & Grant (1963), Maclean (1993), Penry (1994), Sinclair & Hockey (1996), Skinner (1995), Tarboton (2001), Vincent (1947), White (1956).

24. Cape Bulbul

Pycnonotus capensis

French: Bulbul du Cap **German**: Kapbülbül **Spanish**: Bulbul de El Cabo

Taxonomy. *Turdus capensis* Linnaeus, 1766, Cape of Good Hope, South Africa.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species forms a superspecies with *P. barbatus*, *P. nigricans*, *P. xanthopygos*, *P. leucotis* and *P. leucogenys*, possibly including some other species. Parapatric and locally sympatric with *P. nigricans* and, in small area of Eastern Cape Province, with *P. barbatus*; hybridizes extensively with both in narrow transition zones along at least part of boundaries between their respective distributions. Monotypic.
Distribution. SW & S South Africa, in provinces of Northern Cape, Western Cape and Eastern Cape (from just S of R Orange, S along coast, inland to edge of Karoo, and E to R Sundays).

Descriptive notes. 19–21 cm; 28–47·5 g. A medium-large bulbul with slightly peaked crown, giving distinctive, squarish head shape. Head is dark brown, blacker at side, with conspicuous ring of bare white skin around eye; upperparts, including wings and tail, wholly blackish-brown; throat and breast also blackish-brown, upper belly and flanks paler brown, lower belly whitish, vent and undertail-coverts lemon-yellow; iris red-brown; bill black; legs black. Differs from similar *P. nigricans* in having conspicuous white (rather than orange-red) eyering. Sexes alike in plumage, female on average slightly smaller than male. Juvenile resembles adult, but white eyering does not develop before 2–3 months. Voice. Song a series of short phrases, "chip-chee-woodely", "chup-wheet-churry-up" and "pit-peet-pitmajol", similar to that of *P. barbatus* but higher-pitched and more slurred. Contact call "key-link", or rapid, metallic "chit-tee" or "chit-tee-tee" when more anxious; alarm a low "churr" or "churrt"; excited, rapidly repeated "chop-doodle-it" chatter during wing-flicking display.
Habitat. Range of generally shrubby habitats, including tall, shrubby fynbos, coastal scrub, dune forest, riverine bush and gardens; particularly fond of the exotic *Acacia cyclops*. Occurs in *Acacia karroo* woodland along drainage lines at edge of the Karoo, and in dry valley bushveld in Eastern Cape. Generally prefers moist conditions; distribution corresponds with regions of winter or year-round rainfall. Mainly below 500 m.
Food and Feeding. Wide variety of fruits, seeds, nectar and arthropods. In one study, c. 90% of diet comprised vegetable matter, mainly fruits of 23 plant species (principally, in decreasing importance, *Rhus crenata*, *Acacia cyclops*, *Chrysanthemoides monilifera*, *Rapanea gilliana*, *Mundia spinosa*), and 10% arthropods; average dry-weight daily consumption c. 24% of the bird's own weight. Nestling diet mostly arthropods for first six days, thereafter mainly fruit; of items fed to nestlings, 58% were arthropods, 42% fruit. Occurs singly or, more usually, in pairs; outside breeding season, congregates in small foraging flocks, typically of 5–9 individuals, but up to 40 may gather with other frugivores at fruiting trees or to feed on nectar at mass-flowering *Salvia* shrubs. Noisy and conspicuous, often perching on top of bushes. Forages in foliage of trees and shrubs; hawks insects on the wing, and also takes them from flowers. Drinks water regularly, particularly during hot, dry summer months; flocks congregate at water sources.
Breeding. Recorded in Aug–Mar, peak Sept–Oct, in Western Cape (winter rainfall region), and in Sept–Mar, peak Oct–Nov, in Eastern Cape; at least some females double-brooded. Monogamous; usually (not always) pairs for life, and partners remain together throughout year. Solitary, territorial nester, territory 1–2 ha, male sings during dawn chorus from one or more prominent perches, during day song most frequent and sustained (10–23 minutes) during nest-building and early incubation. Courting male gives wing-flutter display with whining call. Nest built by female, rarely assisted by male (but male follows her closely, often singing from nearby bushes), constructed in 2–10 days, mostly during 07:00–11:00 hours, a sturdy, untidy cup of twigs (some with leaves), rootlets and grass stems built on foundation of coarse twigs, lined with finer plant fibres and sometimes sheep's wool, cobwebs, feathers, paper, string and other human rubbish, external diameter 11 cm, depth 6·5 cm, internal diameter 6·5 cm, depth 4·5 cm; located just within outer canopy of leaves of tree or shrub (frequently *Acacia cyclops*), on more or less horizontal outer branch 5–20 mm in diameter, at height of 0·3–4 m; new nest built for second brood, sometimes incorporating material from first nest, one female started second nest 10 days after first brood left, and another was incubating second clutch while male continued to feed first brood 17 days after they had left nest. Clutch 2–5 eggs, mostly 3, first egg laid within 1–4 days of nest completion, subsequent ones usually at 1-day intervals; incubation by female only, not fed by male, period 11·5–13·5 days from clutch completion; chicks fed by both parents, male slightly more, but female does most of brooding, nestling period 10–13 days; chicks usually leave nest before able to fly, capable of controlled

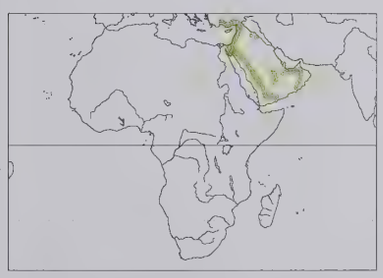
flight at 15 days, fed for at least 2 weeks after leaving nest, at least occasionally for further 2 weeks, appear independent at c. 50 days. Of 233 eggs laid, 63 (27%) produced fledged young; average of 2·1 chicks fledge per successful nest. Nests heavily parasitized by Jacobin Cuckoo (*Clamator jacobinus*), e.g. 12–73% (average 39%) in one area over 4-year study, but many parasitized nests preyed on and losses to cuckoos only 7%; predation rate 60–83%, with mammals, particularly rodents but also vervet monkey (*Cercopithecus aethiopicus*), mongooses (Herpestinae) and felids, responsible for 70%, birds, mainly White-browed Coucal (*Centropus superciliosus*) and Southern Boubou (*Laniarius ferrugineus*), for 16%, and snakes (mainly *Dasypeltis scabra*) for the remainder. Survival rate of fledglings estimated at 18% after 1 month, 10% after 1 year; annual adult mortality rate 25%, mean life expectancy of adult 3·1 years.

Movements. Mainly sedentary; seasonal influxes occur in response to fruiting shrubs. Although some individuals appear to remain on territories throughout year, others vacate them during non-breeding season and join foraging flocks that range more widely.

Status and Conservation. Not globally threatened. Locally common to abundant. Mean breeding density in an area of coastal scrub over 5 years 13·8 pairs/20 ha, range 9–19 pairs/20 ha. Has adapted well to transformed habitats. Reasonably well represented in protected areas, including Tsitsikamma National Park, Anysberg, De Hoop and Marloth Nature Reserves, and Cedarberg Wilderness Area.

Bibliography. Dean & Milton (2001), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Ginn *et al.* (1989), Gray (1998), Hall & Moreau (1970), Harrison *et al.* (1997), Harwood (1973), Keith *et al.* (1992), Lawson (1962), Liversidge (1970), Lloyd (2005b), Lloyd & Palmer (1998), Lloyd, Craig *et al.* (1997), Lloyd, Hulley & Craig (1996), Mackworth-Praed & Grant (1963), Maclean (1993), Sinclair & Hockey (1996), Tarboton (2001), Trendler (1996), Vincent (1947).

25. White-eyed Bulbul



Pycnonotus xanthopygos

French: Bulbul d'Arabie **German**: Gelbsteißbülbül **Spanish**: Bulbul Árabe
Other common names: Yellow-vented Bulbul(!), Black-capped Bulbul, White-spectacled Bulbul

Taxonomy. *Ixus xanthopygos* Ehrenberg, 1833, Arabia = Al Muwaylih, on coast near north end of Red Sea, Saudi Arabia.

Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species forms a superspecies with *P. barbatus*, *P. nigricans*, *P. capensis*, *P. leucotis* and *P. leucogenys*, possibly including some other species. No hybrids with *P. barbatus* known, and ranges apparently barely meet, but an old record of a mixed pair reported. Monotypic.

Distribution. E Mediterranean from CS Turkey, W Syria, Lebanon, Israel and W Jordan S to NE Egypt (Sinai), also W & C Iraq, W & S Saudi Arabia, Yemen, N United Arab Emirates and N & SW Oman.

Descriptive notes. c. 19 cm; 31–46 g. A medium-sized species with whitish to pale grey eyering and yellow vent; the only bulbul in its range. Head is black, browner on hindcrown, contrasting bare eyering white, bluish-white, greyish-white or pale flesh-grey; upperparts grey-brown, in fresh plumage washed olive-yellow, particularly on rump and uppertail-coverts; wings dark grey-brown, slightly darker than upperparts, narrow pale grey-brown fringes on outer webs of flight-feathers and greater upper primary coverts; tail black, central pair of feathers tinged grey-brown; upper chin black, lower chin, rear of ear-coverts and lower cheeks blackish-brown, throat dark brown; breast, flanks and belly pale grey-brown, slightly paler than upperparts, vent and undertail-coverts bright yellow; in worn plumage, face becomes duller, browner, upperparts paler and browner, wings and tail duller and darker (but abraded feather tips bleached paler grey-brown), underparts paler, lower belly grey-white and undertail-coverts paler yellow; iris black, dark brown or brown; bill black or dark bluish-black, paler at base; legs black or slaty blue. Sexes alike, female on average slightly smaller than male. Juvenile has face duller grey-brown, upperparts somewhat paler, feathering softer and looser, particularly on rump and undertail-coverts. Voice. Song, from elevated but not necessarily exposed perch, a monotonous repetition of a single phrase of 2–9 syllables, variously stressed, may be rich and fluty, sometimes a contralto whistle, sometimes deeper and more husky, but usually given in short, disjointed snatches, variously rendered as "bli-bli-bli-bli", "bul-bul-bul-bul", "twur-tu-twéé-teeroo" and similar, or even (in Oman) "tchink-tchink-tchink, kutchi-kutchi-kutchi, tiwink-tiwink-tiwink"; seems to vary regionally, and possible that this variation similar to that of *P. barbatus*, neighbouring territorial males of which have similar repertoires but more distant birds have no phrases in common. Occasionally mimics other birds, e.g. Thrush Nightingale (*Luscinia luscinia*), Common Blackbird (*Turdus merula*) and Golden Oriole (*Oriolus oriolus*). Calls include thin, faint chirping and whistling sounds in greeting after short period of separation, louder, sharper calls rendered "MINE, you're MINE, you're MINE" after more extended separation and also in confrontations, and bubbling courtship call; alarm or threat call a sharp, burry, scolding "weck", "trratsh" or "pwitch", often repeated with gathering intensity to become penetrating, high-pitched chatter and used to threaten conspecifics and when mobbing.

Habitat. Wide range of well-vegetated areas with low trees and bushes, in both natural vegetation and cultivation, including open pine (*Pinus*) woods, juniper (*Juniperus*) forest, *Ceratonia* scrub, thick bush in wadi beds, trees and bushes in open semi-desert, oases, orchards, groves, fields, gardens and villages. Sea-level to at least 1000 m in Turkey, to 1300 m in Israel, to 2000 m in Egypt and even higher in Saudi Arabia.

Food and Feeding. Mostly fruit, also seeds and invertebrates; less frequently, nectar, leaves and flowers. Eats wide variety of wild and cultivated fruit, including *Azadirachta*, *Nitraria*, *Opuntia*, dates, mulberries, peaches, plums, tomatoes, strawberries; small fruits swallowed whole, larger ones nibbled. Takes leaves and petals of *Erythrina* and *Iris*. Invertebrates eaten include flies (Diptera), moths (Lepidoptera), hymenopterans (alate ants, bees, wasps), orthopterans, spiders (Araneae), earthworms, gastropod snails. Also reported as eating carrion. Nestling diet initially only insects and spiders, later increasing proportion of fruit. Insects often taken in aerial sallies from tree perch, particularly at dusk; also gleans from leaves, sometimes hover-gleans, and descends to ground level to forage among fallen vegetation. Recorded as chasing Hoopoes (*Upupa epops*) to steal mole-crickets (*Gryllotalpa*). Inquisitive, noisy, cheerful; tame around settlements, more cautious elsewhere. Gregarious all year. Usually occurs in pairs, or in "duos" comprising two siblings of same or different sex which associate closely. Often gathers in greater numbers at locally abundant food sources; flocks of 25–40 recorded in Jordan and of several hundreds, even thousands, in Israel, particularly at end of breeding season, when up to 83% of such flocks comprise first-year birds. Pairs or duos territorial all year, but territory less aggressively defended in non-breeding season, will leave temporarily to join noisy feeding flocks; movements of a few kilometres between feeding stations may occur daily. Feeding activity of flocks often begins before sunrise and usually ends in late afternoon, up to half an hour before sunset.

Breeding. End Mar to end Aug in Israel, from late Apr in Oman, from Feb in Saudi Arabia (newly fledged young Jul), Mar in Gulf states, fledgling in Mar in Egypt; mostly two broods, sometimes three, in Israel, suspected as triple-brooded in Saudi Arabia. Monogamous; pair-bond maintained all year and for several years. Territorial, solitary nester; territory vigorously defended by both sexes by vocalization and aggressive displays, including pumping of spread tail, sometimes with wings lowered and head plumage ruffled, by loud-calling male, also upright threat display with neck stretched, bill pointed upwards and plumage sleeked, and direct attack. Nest built by female, taking 4–7 days, a cup or small basket of thin twigs, grass stems, moss and leaves, base constructed of broad leaves (sometimes with newspaper, strips of plastic or cotton wool), structure held together by cobwebs and cotton threads, lined after a fashion with hair, shredded bark and rootlets, apparently sometimes unlined, external diameter 8–10 cm, internal diameter 6·5 cm, cup depth 4–5 cm; placed among thin branches 1–2·5 m above ground in low palm or bush; in Israel, territory size a few hundred square metres (average minimum inter-nest distance 200 m) and territories usually contiguous in favourable habitat, much smaller (0·05–0·19 ha) in urban situations than in desert areas. Clutch 2–4 eggs, usually 3; many replacement clutches laid, as losses frequent; incubation by female, period 13–14 days; chicks fed initially by female, then by both parents, brooded at night for first week by female, leave nest after 13–15 days, fly c. 10 days later; young able to feed themselves after 4 weeks, independent at 6 weeks; after leaving parental territory, brood-members remain in duos or often trios, in latter case one gradually severing links and joining another, unrelated individual, and duo-members forming bond with non-sibling of opposite sex after 4–6 months. Success low, only 15–35% of eggs laid reach chick stage; in natural habitats many nests destroyed by fire or preyed on by snakes and small mammals, while in orchards and woods many lost to Eurasian Jays (*Garrulus glandarius*). Age of first breeding sometimes 1 year, often 2 or more.

Movements. Mostly resident; some local wandering in search of fruit sources. Altitudinal migration recorded in Israel, and may occur in Turkey. Some young disperse over short distances.

Status and Conservation. Not globally threatened. Fairly common to abundant throughout its range. Israel population estimated at a few hundred thousand pairs in 1980s; estimated 5,000–10,000 pairs in United Arab Emirates. Has benefited from a number of anthropogenic habitats. Considerable expansion of range in some areas since c. 1930s, attributable at least in part to development of settlements and spread of cultivation of fruit crops into desert areas; recent records from Iraq may be a continuing manifestation of this process. Often causes extensive damage in orchards etc. Regarded as an agricultural pest in some places; may be killed legally in Israel, where 670 were trapped within area of 0·5 ha in a 9-day period in Jun 1984.

Bibliography. 26. White-eared Bulbul

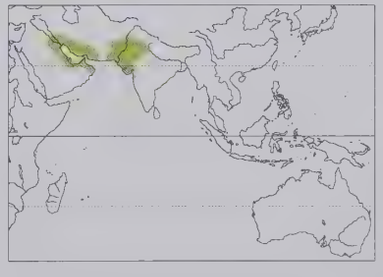
Pycnonotus leucotis

French: Bulbul à oreillons blancs **German**: Weißohrbülbül **Spanish**: Bulbul Orejiblanco
Other common names: White-cheeked Bulbul(!)



Taxonomy. *Ixos leucotis* Gould, 1836, Karachi, Sind, Pakistan.

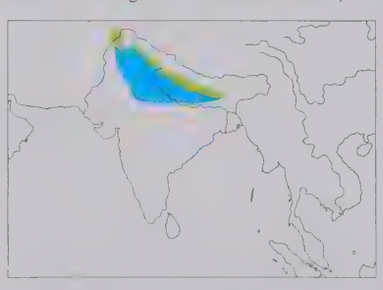
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species forms a superspecies with *P. barbatus*, *P. nigricans*, *P. capensis*, *P. xanthopygos* and *P. leucogenys*, possibly including some other species. Hybridizes with last-mentioned in E Afghanistan and N Pakistan (putative race *humii* represents a hybrid swarm) and often treated as conspecific, but differs morphologically, and hybridization zone is relatively abrupt. Elsewhere, sometimes hybridizes with *P. cafer*, including in Oman (where latter introduced). Old record of mixed pair of present species and *P. barbatus*, but no hybrids known (and ranges apparently do not meet). Race *mesopotamia* (erroneously emended to to "*mesopotamiae*") only marginally differentiated and its validity requires review. Proposed races *farahensis* (Afghanistan) and *dactylus* (Saudi Arabia) not reliably distinguishable. Two subspecies recognized.

Subspecies and Distribution.

P. l. mesopotamia Ticehurst, 1918 – E & SE Iraq, S Iran and Kuwait; also E Saudi Arabia (and probably introduced inland, at Riyadh) S to United Arab Emirates, Qatar and Oman (probably introduced).

P. l. leucotis (Gould, 1836) – SE Afghanistan, Pakistan (except far N) and NW India (E to W Uttar Pradesh and N Madhya Pradesh, also NW Maharashtra).

Descriptive notes. 17·5–19 cm; 18–28 g (nominate), 29–35 g (*mesopotamia*). Medium-sized, lively, conspicuous bulbul, virtually uncrested. Has black head and throat, with large white patch on side of head; upperparts relatively pale grey, becoming even paler on rump; breast also relatively pale, hardly darker than lower underparts; vent and undertail-coverts bright orange-yellow; iris dark brown or hazel, pale bare eyering dull greyish to dull yellowish; bill blackish-horn; legs bluish-grey to slaty black. Differs from rather similar *P. leucogenys* in slightly smaller size, lack of crest, thicker and shorter bill, and colour of vent. Sexes similar. Juvenile has brown replacing black on head, and paler body, wings and tail, paler yellow undertail-coverts. Race *mesopotamia* is on average slightly larger than nominate, with longer wing and tail, larger and stouter bill, yellow eyering. Voice. Song a brief, rapid complex chatter, sometimes preceded by a few dry chirps; generally quicker, harder and less squawky than song of *P. leucogenys*, and much clearer and less guttural, includes more notes than song of *P. cafer* and does not descend strongly. Sometimes contains segments of mimicry. Calls a short, slightly harsh and nasal "nyuk, nyuk", or mellow "pip" and "pip-pip".



Habitat. Dry woodland, thorn-scrub, semi-desert scrub (with *Capparis*, *Salvadora* and *Carissa* bushes), riverine shrubbery, mangroves, palm groves (sometimes small and isolated), gardens, agricultural land and orchards. Sometimes frequents tall reedbeds, especially when roosting. Often breeds in *Euphorbia* woodland. In Pakistan the dominant bird in *Olea cuspidata* and *Dodonaea viscosa* scrub. Lowlands, rarely to 2100 m; usually replaced at higher altitudes by *P. leucogenys* in Pakistan and India, and by *P. xanthopygos* in Oman.
Food and Feeding. Feeds on fruit (including *Capparis*, *Ziziphus*, *Salvadora*) and buds, also nectar (e.g. *Capparis*); also large amounts of invertebrate food, including caterpillars and alate ants (Hymenoptera) and termites (Isoptera). Usually encountered in pairs or small groups, sometimes in flocks of 20–30 individuals. Often descends to the ground in quick sallies, or hops around for more extended periods, to feed on insects, seeds and other items; probes flowers to feed on nectar, or on the insects gathered there. Flying ants and termites often caught in short, clumsy aerial sallies.
Breeding. Feb–Sept; usually Apr–Jul in Iraq and Jul–Sept in India (Punjab and Gujarat). Trios of adults regularly seen during breeding season, suggesting that some possible communal breeding with helpers, but verification needed. Display includes spreading and fluttering of wings and tail by male, and fanning of bright vent plumage. Nest a simple but firmly built cup-shaped structure, composed of fine twigs, rootlets, grass and other plant fibres, sometimes unlined, usually neatly lined with slender fibres; both partners visit nest-site together during building phase, but only one (presumably female) brings material, suggesting that male mate-guards female during fertile period; nest usually fairly low, 0·8–3·2 m above ground (average 1·36 m for 20 nests in Iraq), and in huge variety of situations, most often in almost any type of shrub or small tree available, including bramble (*Rubus*), *Tamarix*, *Capparis*, *Ziziphus*, *Dodonaea*, *Acacia nilotica*, *Prosopis*, *Lagerstroemia*, citrus tree, date palm (Arecaceae), pomegranate (Punicaceae), mulberry bush (Moraceae), poplar (Salicaceae), *Eucalyptus*, often in candelabra-like stems of *Euphorbia caducifolia*; in Iraq sometimes in tall "sarkanda" (*Saccharum spontaneum*) grass and, perhaps regularly, in reedbeds alongside R Euphrates; more unusually, in tall broad-bean crop, on limestone rock ledge, on verandah, under eaves, in *Bougainvillea* growing against house, in wall of reed hut, in reed frame supporting melon plants, and inside building. Clutch 2–4 eggs, usually 3, extremely rarely 5; incubation by female, period 13–14 days in Pakistan, 10·5–12·5 days in Iraq; chicks fed by both sexes, nestling period 9–11 days in Iraq. Of 19 nests in Iraq, only three (16%) produced young; predation by crows (Corvidae) probably high, as many nests poorly concealed.
Movements. Largely resident, but subject to local movements; poorly understood seasonal migrations. In lower-lying regions of N & C Pakistan large numbers of non-breeding visitors augment resident population in winter, or arrive where no breeding population present. Summer visitor in Chitral (Hindu Kush), in NW Pakistan, arriving Mar and leaving Oct. Around NE shores of Persian Gulf, arrives in numbers in Sept, and leaves again in Jun. In Iraq and Iran, occurs in small, very isolated date palm groves in open desert, suggesting that it disperses well across inhospitable country. Records from Israel and Jordan possibly refer to escaped captives.
Status and Conservation. Not globally threatened. Locally common and conspicuous in many regions, including N India, much of Pakistan (e.g. Baluchistan), S Iraq and lower reaches of R Euphrates. Previously common (the "very commonest bird") in Sind (Pakistan), but now quite scarce and replaced in urban and irrigated areas by *P. cafer*. This species is commensal with man and faces no threats, apart from irrigation of a few desert regions.

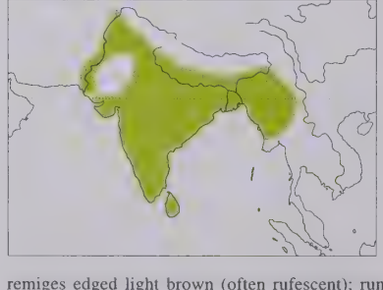
27. Himalayan Bulbul

Pycnonotus leucogenys

French: Bulbul à joues blanches **German**: Himalajabülbül **Spanish**: Bulbul Cariblanco
Other common names: White-cheeked Bulbul(!)

Taxonomy. *Brachypus leucogenys* J. E. Gray, 1835, Kashmir.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species forms a superspecies with *P. barbatus*, *P. nigricans*, *P. capensis*, *P. xanthopygos* and *P. leucotis*, possibly including some other species. Hybridizes with last-mentioned in E Afghanistan and N Pakistan (putative race *humii* represents a hybrid swarm) and often treated as conspecific, but differs morphologically, and hybridization zone is relatively abrupt. In addition, form described as *Molpastes magrathi* is a hybrid between present species and race *intermedius* of *P. cafer*. Proposed race *picru* (Afghanistan, Pakistan, Kashmir) poorly differentiated, based on clinal size difference, and considered untenable. Monotypic.
Distribution. Breeds E Afghanistan and Himalayas of N Pakistan E through Nepal to NE India (at least to R Dihang, in NE Arunachal Pradesh).



Descriptive notes. 19–20 cm; 34–38 g. Medium-sized, jaunty, conspicuous bulbul with prominent forward-pointing crest. Has prominently white cheeks, black crescent at base of white ear-coverts; upperparts brownish-grey; throat and upper breast blackish, rest of underparts pale greyish, vent and undertail-coverts yellow; iris dark brown or hazel, black eyering; bill blackish; legs pinkish-grey to slaty black. Differs from *P. leucotis* in prominent crest, head pattern, yellow (rather than orange-yellow) vent, slimmer and longer bill. Sexes similar. Juvenile has paler brown plumage overall, including crown and throat. Voice. Song a short, loud, burbling phrase with some notes raspy, others clear, e.g. "chik, chek, churr-Wick", or just "churr-Wick"; also a similar but more complex tumbling song with more notes, and a more halting, free-form version; compared with *P. cafer*, notes are thinner, crisper and more random (less syncopated, more complex). Calls include song fragments interspersed among songs; also said to give loud, short, buzzy, upslurred "bzzrrp", often quickly repeated, and "plee-plee-plee" flight call; larger winter flocks produce cacophony of jumbled call notes.
Habitat. Breeds in wooded valleys, also bushy hillsides, often covered with wild raspberry (*Rubus*) and *Berberis*, and hedgerows, groves, parks, gardens and even town centres. This or a hybrid form occurs locally in *Pinus gerardiana* forest in Pakistan. Currently expanding into deforested areas. Usually at 300–2400m (in W of range), sometimes higher where trees are fruiting; sometimes descends to level lowlands in winter.
Food and Feeding. Diet includes berries and other fruits, e.g. *Carissa opaca* and mistletoes (Loranthaceae), as well as variety of buds and seeds; attacks commercial crops. Hybrids ("*humii*") noted as eating berries of *Ziziphus vulgaris* and "Persian lilac" (*Melia azedarach*) in Pakistan. Also eats many invertebrates, e.g. termites (Isoptera) and ants (Hymenoptera). Usually found in pairs or small parties; occasionally large flocks in non-breeding season. Boisterous, often perching atop bushes and constantly flicking wings and tail. Often very tame, coming to picnic sites and outdoor cafes to steal crumbs and sugar. Often comes to ground to pick up invertebrates, snatching them off branches, or catching them in brief aerial sallies.
Breeding. Apr–Aug, rarely Mar. Nest built mainly or entirely by female, a shallow, sometimes flimsy, cup-shaped structure of fibres, woody plant stems and grass, lined with rootlets and fine grass, usually placed low (0·5–3 m) above ground in tree or bush; often in garden or around building, where regularly tucked into thatched rooftop, or in vines climbing tree or wall. Clutch 3–4 eggs, rarely 5; when clutch lost, replacement laid shortly after; incubation seem to be mainly or entirely by female, but both parents tend nestlings and fledglings; no information on incubation and nestling periods; both sexes observed injury-feigning to lead predators from fledglings. Predation by e.g. crows (Corvidae) probably high, as many nests poorly concealed.
Movements. Resident in many areas (e.g. Kashmir), but prone to seasonal or altitudinal migrations in others. Part of population descends to lower slopes, occasionally to lowland plains, in winter, resulting in sightings far from Himalayas, including L Harike (Punjab). Partially migratory in N Pakistan, where some remain throughout year; numbers increase dramatically in spring, when breeding visitors arrive.
Status and Conservation. Not globally threatened. Generally common to abundant, e.g. in Himachal Pradesh, Kashmir, Nepal etc. Benefits from deforestation and lives commensally with humans; unlikely ever to be at any great risk. Popularly sold in captivity in Pakistan; where trapping a common activity, its range and status should be monitored. In some regions, classed as an agricultural pest for damaging crops such as peas, currants, raspberries.
Bibliography. Ali & Ripley (1996), Ali *et al.* (1996), Basil-Edwardes (1921), Bates & Lowther (1952), Betham (1918), Cock & Marshall (1873), Cramp (1988), Dickinson & Dekker (2002b), Dickinson *et al.* (2002b), Fleming *et al.* (1984), Grimmett *et al.* (1998), Hingston (1921), Hüe & Étchécopar (1970), Inskipp & Inskipp (1991), Jones (1919), MacKinnon & Phillipps (2000), Magrath (1908, 1909), Mason & Lefroy (1912), Paludan (1959), Perreau (1910), Rasmussen & Anderton (2005), Ripley (1982), Roberts (1992), Robson (1997b, 1999a), Scully (1879), Stevens (1923–1925), Ward (1906–1908), Whistler (1922b, 1930), Whistler & Kinnear (1911), Whitehead (1910–1911).

28. Red-vented Bulbul

Pycnonotus cafer

French: Bulbul à ventre rouge **German**: Rußbülbül **Spanish**: Bulbul Cafre

Taxonomy. [*Turdus*] *cafer* Linnaeus, 1766, Cape of Good Hope; error = Pondicherry, south-east India.
Type locality has twice been corrected, first from South Africa, secondly from Sri Lanka; Sri Lankan race therefore no longer the nominotypical one. Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species forms a superspecies with *P. aurigaster*; sometimes treated as conspecific owing to interbreeding in Myanmar; hybrids earlier described incorrectly as separate species (*P. nigropileus* and *P. burmanicus*). In NW India, often hybridizes with *P. leucogenys*; hybrids between latter and race *intermedius* of present species incorrectly described as a separate species (*Molpastes magrathi*). Sometimes hybridizes also with *P. leucotis*. Race *saturatus* was invalidated (and replaced by *wetmorei*), as preoccupied by a race of *Andropadus latirostris*, which was previously placed in present genus. Some listed races weakly differentiated or perhaps described from mid-points of clines or hybrid zones; full review needed. Several described races considered too weakly differentiated and therefore synonymized: thus, in India, *primrosei* (Assam) and *afer* (Meghalaya) are junior synonyms of *bengalensis*, and *vicinus* (Mysore) and *pusillus* (NE Tamil Nadu) junior synonyms of nominate. Eight subspecies provisionally recognized.
Subspecies and Distribution.
P. c. intermedius Blyth, 1846 – W Himalayas from Pakistan, Jammu and Kashmir E at least to Nepal.
P. c. humayuni Deignan, 1951 – SE Pakistan (Sind) and NW & NC India (including N plains).
P. c. bengalensis Blyth, 1845 – C & E Himalayas and Gangetic Plain, and Bangladesh.
P. c. stanfordi Deignan, 1949 – NE India (S Assam hills), N Myanmar and S China (W Yunnan).
P. c. melanchimus Deignan, 1949 – S Myanmar and N Thailand.
P. c. saturatus (Whistler & Kinnear, 1932) – NE Peninsular India.
P. c. cafer (Linnaeus, 1766) – S India.
P. c. haemorrhousus (J. F. Gmelin, 1789) – Sri Lanka.
Introduced Polynesia, including Fiji, Samoa and Tonga (*bengalensis*); also E Arabia (Kuwait, Qatar, United Arab Emirates, Oman) and Hawaii (Oahu) (races unknown).

Descriptive notes. 19–20 cm; 28–40 g. Medium-sized, noisy, conspicuous bulbul, generally dark brown and scaly-looking, with bushy crest. Nominate race has black hood, brown upperparts with pale feather margins, prominent white rump, white-tipped black tail; breast brown, feathers pale-fringed, paler below, vent and undertail-coverts bright red; scaly tips of feathers wear off, changing appearance markedly; iris dark brown or hazel; bill black; legs black, soles grey; claws black, occasionally fleshy white. Sexes similar. Juvenile resembles adult, but duller and browner on head and throat, less scaled above, feathers of mantle and remiges edged light brown (often rufescent); rump buffy white, rectrices tipped dull brownish, undertail-coverts pale pink or buff, bill yellowish-horn. Races differ mainly in depth of colour tones, extent of black hood, also in size, generally larger and darker in N, more scaly in S: *humayuni* has paler brown mantle and whiter underparts than nominate; *intermedius* has black hood extending to upper mantle and mid-breast, with heavily grey-scaled upperparts and lower breast, pale lower underparts; *bengalensis* is large, with dark, almost unscaled hood covering mantle and breast (little contrast between crown and mantle), darker ground colour of most feathers (especially no-

ticeable on mantle and breast); *stanfordi* has hood extending to upper mantle and mid-breast, heavy grey scaling above and on lower throat and breast (very like *intermedius*, but slightly darker ground colour, greyer scaling); *melanchimus* is similar to previous, but underparts more extensively dark, upperpart feathers with darker centres and narrower ashy fringing; *saturatus* is intermediate, with sharply defined cap, black ear-coverts, relatively dark mantle, reduced white below; *haemorrhousus* has dark mantle with narrow pale edges. Voice. Produces loud gurgly notes almost constantly. Songs of S races include loud, jaunty, guttural chuckling "kreink-kergrr", inflected downwards, also in rapid squawky descending version, and numerous other variants, both shorter and longer; songs of N races similar but descend less markedly; dialects detectable in different portions of range. Calls include very harsh, guttural, staccato, 2-note "tik-jhurk", second note upturned, or more prolonged "tik-jhuurrh", second note downslurred; also isolated song-type gurgly notes, and explosive "jzzrk" rasps; calls of *melanchimus* include "peep-peep-peep", "peet-wit-wit-wit", and more rapid "pitititi".

Habitat. Drier deciduous woodland, sparse secondary forest, scrub, orchards and gardens, including in large cities, and even extending into sparse stony landscapes with scattered scrub and cactus; usually avoids humid evergreen forest and barren areas away from settlements. Commonly in cinnamon plantations in Sri Lanka. In Myanmar, birds identified as "*burmanicus*" attended huge communal roosts in canebrakes. Occurs from plains, valleys and foothills up to c.1600 m; regularly to 2285 m in Himalayas.

Food and Feeding. An opportunist and generalist; diet includes fruit, nectar, buds and invertebrates, occasionally vertebrates. In Pakistan, said to feed largely on young buds, green leaves and fallen seeds in winter; in Myanmar, recorded as eating grass seeds. Fruits collected from many trees, shrubs and parasitic plants, including *Salvadora*, *Santalum*, *Ziziphus*, *Ficus*, mistletoes (Loranthaceae), wild raspberries (*Rubus*) and *Lantana*; cultivated crops also exploited. In S India (Point Calimere, in Tamil Nadu), noted to feed on fruits from very broad variety of plants (e.g. *Pachygone*, *Tinospora*, *Capparis*, *Flacourtia*, *Hugonia*, *Glycosmis*, *Toddalia*, *Azadirachta*, *Walsura*, *Olax*, *Cansjera*, *Pleurostylia*, *Salacia*, *Scutia*, *Ziziphus*, *Cissus*, *Allophyllus*, *Lepisanthes*, *Lannea*, *Syzygium*, *Memecylon*, *Coccinia*, *Opuntia*, *Benkara*, *Canthium*, *Ixora*, *Pavetta*, *Manilkara*, *Diospyros*, *Jasminum*, *Azima*, *Salvadora*, *Carissa*, *Carmona*, *Cordia*, *Ehretia*, *Solanum*, *Premna*, *Breynia*, *Drypetes*, *Phyllanthus*, *Securinegra*, *Asparagus*, *Phoenix*). Commonly visits flowers of trees and shrubs to eat nectar or buds (e.g. *Capparis*, *Erythrina*, *Prunus*, *Salmalia*, *Spathodea campanulata*, *Woodfordia fruticosa*, *Loranthus* and *Careya arborea*); individuals also noted as eating petals, including those of *Bauhinia variegata*, *Tecomella undulata* and *Pisum sativum*, and whole flowers of *Clitoria ternatea*, *Clerodendron infortunatum* and *Tabernaemontana divaricata*. Invertebrate component of diet seems to be large; includes adult and larval lepidopterans, dipterans (e.g. mosquitoes), ephemeropterans (e.g. mayflies), hymenopterans (e.g. ants, including *Camponotus compressus*, and bees), coleopterans (e.g. *Myllocerus* weevils), hemipterans (e.g. aphids), winged termites (Isoptera), cockroaches (Blattodea) and orthopterans (e.g. *Chrotogonus*). Caterpillars found to be important part of diet of adults and nestlings during breeding season in S India (Tamil Nadu). Prey not always small; one adult attacked and consumed a large preying mantis (Mantidae). One attacked and maimed (but not seen to consume) a 4-cm house gecko (*Hemidactylus flaviviridis*), and another seen to eat recently ejected tail of same; record of nestling 5–6 days old being fed with 9-cm juvenile lizard (*Calotes versicolor*) and dying shortly after trying to eat it. Often in pairs; also large loose flocks in non-breeding season, sometimes assembling in fruiting trees, e.g. up to 100 individuals can be attracted to large fruiting fig (*Ficus*). Usually arboreal, but often captures prey in short aerial sallies from perch, sometimes vertically upwards; also regularly descends to ground and hops about.

Breeding. Breeds Apr–Oct (mainly Jun–Jul) in W India, although usual season given as Aug–Mar (associated with fruiting season) in Tamil Nadu; in Sri Lanka thought to follow rainfall patterns, nests Jan–May in W & S, with second broods as late as Aug–Sept, and first brood Oct–Dec in E (i.e. during monsoon); in Myanmar, May–Sept in N and Apr–Aug in S; Apr–Jul in N Thailand; up to four broods annually. Occasionally two or more pairs nest in fairly close association, almost in loose colony. In apparent courtship display, male spreads out wings above head and slowly flutters them up and down while tail fanned and depressed. Nest a simple cup, sometimes neat, sometimes flimsy, built from variety of materials, depending on availability, usually grasses, plant fibres and rootlets, bound with cobwebs, lined with fine grass, mammalian hair and other slender fibres; 70% of nests in Tamil Nadu had outer wall formed with dry petioles of *Cassia auriculata*, along with stems and branches of a few other herbs, this wall often covered by layer of *Desmodium triflorum* strands, inner lining invariably of slender stems of the grass *Eragrostis tenella*, elsewhere in India two nests in an industrial estate constructed 50% of copper wire and 50% plant material; nest usually 2–3 m up, regularly lower (down to 0·5 m) or higher (to 18 m), in upright fork or similar site in shrub, tree, creeper, palm, hedge or cactus, in Tamil Nadu preferentially in thorny bush (most in *Xeromphis spinosa* and *Dichrostachys cinerea*); a few records of nests almost on ground in tufts of grass, in E of range (race *stanfordi*), and many others found in highly man-modified situations, including on top of stump in the open, in potted house-plant, on chandelier in drawing room, and on luggage rack of Indian bus (in daily operation); previous year's nest sometimes reused. Clutch 2–4 eggs, usually 2–3 in S of range, 3–4 in N; incubation mainly or entirely by female, usually from second egg, period 11–14 days; chicks fed by both sexes, nestling period 12–16 days (usually 12 days); young fed for at least 6 days, probably much longer, after fledging. Broods sometimes parasitized by Jacobin Cuckoo (*Clamator jacobinus*). Nests often ill-concealed, prone to predation; of 134 eggs in Tamil Nadu, only 8·3% survived to fledging, predators were snakes, mongooses (*Herpestes*), coucals (*Centropus*) and blue-magpies (*Cissa*); in Pakistan often robbed by crows (Corvidae) and adult *Calotes* lizards, and one nestling consumed by saw-scaled viper (*Echis carinatus*).

Movements. Resident, but subject to local movements in response to environmental conditions. In India, W populations may follow rain into driest areas, NE populations descend from mountainous regions in cold weather, and lowland S populations move uphill in hot season. Thought to be partially migratory in Bhamo district of Myanmar, where large numbers arrive to breed, probably having wintered at lower altitudes. Roosts communally, sometimes in large numbers, in non-breeding season.

Status and Conservation. Not globally threatened. Generally common and familiar, even in heavily populated areas. Abundant throughout much of India, Sri Lanka, Nepal and Bangladesh; rare in S China. In Pakistan, previously scarce and local in Sind, but generally common around Lahore; spread of irrigation through Sind has resulted in massive expansion of population and range in this region. Status in Myanmar poorly known. First recorded in Thailand in Feb 1996. This species is a common cagebird in many regions, but trapping pressure has not affected its population. An active seed-disperser and pollinator for many plants, it thus plays a vital ecological role. It is, however, an agricultural pest, noted to damage crops of wide range of hard-skinned and soft fruits and pulses, among others.

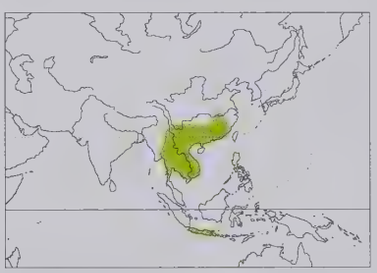
29. Sooty-headed Bulbul

Pycnonotus aurigaster



French: Bulbul cul-d'or **German**: Kotilangbülbül **Spanish**: Bulbul Ventridorado

Taxonomy. *Turdus aurigaster* Vieillot, 1818, Caffraria; error = Java.

Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. This species forms a superspecies with *P. cafer*; sometimes treated as conspecific owing to interbreeding in Myanmar; hybrids earlier described incorrectly as separate species (*P. nigropileus* and *P. burmanicus*). Several variable populations in Myanmar and S China reflect a hybrid origin; further review necessary, and some listed races may not be valid. Proposed races *deignani* (SE Thailand) and *innitens* (SC Thailand) indistinguishable from *thais*; and *chrysorrhoeus*, *crocorrhous* (both Java) and *martini* (Sumatra) inseparable from nominate. Races *chrysorrhoides* and *resurrectus* formerly known respectively as *atricapilla* and *insularis*, but these two names invalid, as preoccupied. Nine subspecies provisionally recognized.

Subspecies and Distribution.

P. a. latouchei Deignan, 1949 – S China (SW Sichuan and W & S Yunnan E to S Hunan and NE Guangxi) and E Myanmar E to NE Thailand, N Laos and N Vietnam (W Tonkin).
P. a. chrysorrhoides (Lafresnaye, 1845) – SE China.
P. a. resurrectus Deignan, 1952 – N Vietnam (E Tonkin, N Annam) and SE China (W Guangdong, Nao Chow Tao).
P. a. klossi (Gyldenstolpe, 1920) – SE Myanmar and N Thailand.
P. a. schauenseei Delacour, 1943 – S Myanmar (C Tenasserim) and SW Thailand.
P. a. thais (Kloss, 1924) – C & SE Thailand and C Laos.
P. a. dolichurus Deignan, 1949 – C Vietnam (C Annam).
P. a. germani (Oustalet, 1878) – extreme SE Thailand, Cambodia and S Indochina.
P. a. aurigaster (Vieillot, 1818) – Java; Bali (possibly introduced).
Introduced (nominate race) in Singapore, Sumatra, Borneo (Kalimantan), S Sulawesi (in and around Ujung Pandang) and Buton I.

Descriptive notes. 19–21 cm; 40–50 g. Medium-sized, garrulous, conspicuous bulbul with short crest. Nominate race has lores and face to below and around eye dull black, cap slightly glossy black; ear-coverts white, sometimes tinged pale brown; upper neck pale ash-grey; mantle and back greyish-brown with paler grey fringing (blotchy effect), becoming paler ash-grey on rump and white on uppertail-coverts (conspicuous in flight), longest rump feathers tipped pale grey; lesser and median wing-coverts as mantle, greater coverts dark brown with narrow pale grey outer webs; tertials and secondaries as their coverts; primary coverts sooty brown with pale ash-grey tips, primaries the same except that outer webs also finely edged pale grey; tail sooty black, prominently tipped white; chin and upper throat dull black, lower throat white; breast and flanks whitish, sullied unevenly with pale grey; mid-belly whitish, undertail-coverts bright golden yellow; iris dark brown or reddish-brown; bill and legs black. Sexes alike. Juvenile has browner crown, paler cheeks, and duller, paler vent. Race *resurrectus* has entire underparts suffused smoky buff; *chrysorrhoides* is larger than nominate, with more uniform mantle, longer crest feathers, bright red vent; *dolichurus* is similar to previous, but shorter wings, virtually unglossed black crown, scarlet-red undertail-coverts; *latouchei* is also similar, but has upperparts slightly darker greyish-brown, fringed with darker ashy; *klossi* differs from last in relatively small size, shorter crest, slightly browner upperparts (whitish-brown fringes, producing mottled effect), scarlet-red undertail-coverts; *schauenseei* is like previous but smaller still, with shorter crest, slightly browner above and below, smaller and greyer tips of rectrices, and undertail-coverts rosy red to red-orange (variable); *thais* has relatively unglossed crown, undertail-coverts rich yellow to bright red (variable); *germani* has crown feathers dull brown and unglossed (with paler fringing), other head markings dull brown, pale rump less pronounced, undertail-coverts chrome-yellow, white tips of outer rectrices smaller and duller than previous. Voice. Song chatty and cheerful, a shrill, gurgly sequence as "whi-wi-wiwi-wiwi", usually with stressed introductory note, also as "u'whi'hi'hu" or "wh'i-i-wi". Also produces sharp single or double notes, varying in pitch and intonation.

Habitat. Scrub, second growth, grassy areas, forest clearings, woods, towns, gardens, cultivation; favours thinly wooded hillsides, scattered pines (*Pinus*) and dry agricultural areas in S China. Generally in lowlands, but ascending locally to 1830 m.

Food and Feeding. An opportunist and generalist, probably ecologically similar to *P. cafer* but much less studied. In pairs during breeding season; non-breeding flocks in S China sometimes contain 80 individuals. Often descends to the ground.

Breeding. Generally Mar–Apr in SE Asia and Mar–Jul in S China; throughout year, but most often in Mar–Jun and Aug, in Java; multi-brooded. Nest a compact but flimsy, cup-shaped structure, usually situated in bush or small tree, 1–3 m above ground, sometimes a little lower or much higher. Clutch 2–4 eggs, very rarely up to 6; no information on incubation and fledging periods.

Movements. Resident.

Status and Conservation. Not globally threatened. Common in Hong Kong, and fairly common over a broad range in S China; fairly common in SE Asia. Common in Java, despite heavy trapping for cagebird trade. Being commensal with man in many regions, and tolerant of human perturbations of the natural environment, this species is not likely to become threatened.

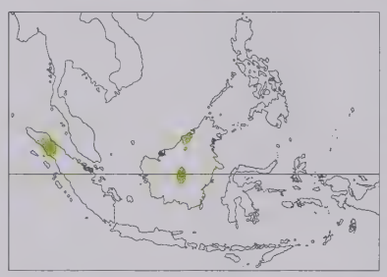
30. **Puff-backed Bulbul**

Pycnonotus eutilotus

French: Bulbul laineux **German**: Wollrückenbülbül **Spanish**: Bulbul Lanudo
Other common names: Puff-backed Brown Bulbul

Taxonomy. *Brachypus eutilotus* Jardine and Selby, 1837, Singapore.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Aberrant member of genus, possibly better treated in a separate genus, *Euptilosus*. Perhaps more clearly allied to other "bar-backed" forms (e.g. *P. nigriceps*) than to "typical" ones (e.g. *P. capensis* and *P. cafer* complexes). Monotypic.
Distribution. Extreme S Myanmar (extreme S Tenasserim), S Thailand, Peninsular Malaysia, Sumatra, Bangka and Borneo.

Descriptive notes. 20–22 cm; 30–43 g. A chunky, bicoloured, relatively quiet bulbul with large bill, short crest often raised at shallow angle; feathers of lower back dense and elongated, sometimes raised into a "puff" and revealing blackish bases. Whole face, including ear-coverts and down to jaw level, is ashy grey; crown brown with greyish tinge, central feathering slightly elongated; upper neck to rump dark rich brown, feathers of lower back to rump dark sooty brown at base, rump feathers black laterally and across rear edge, these parts broadly tipped whitish; uppertail-coverts chestnut-brown; upperwing-coverts and tertials as mantle; secondaries, primary coverts and primaries the same, except that inner webs are dark sooty brown and outer webs edged rufous-olive; tail dull chestnut-brown, outer feathers boldly tipped white on inner webs; whitish below, breast washed greyish, flanks ashy, lower belly and vent tinged light yellow; underwing creamy white, primary coverts sooty, carpal feathering buff-yellow, axillaries silky white; iris light red to crimson (variaton age-related?); bill black; legs dark slaty grey. Sexes similar, female possibly with slightly less prominent white tail tips. Juvenile is like adult, but tail pale-fringed only, without white flashes. Voice. Usually rather silent, but presence often revealed by a "whimsical trill" from high perch, difficult to describe but sounding like loud, rather high-pitched, slurred, quavering warble with first note more emphatic, "tchui'uui tch'i-iwi'iwi, iwu'iwi-u", or "tch'uwi'i'iwi"; at its simplest can be transcribed as "celery-celery", but many variants more complex, becoming soft, hurried yodel with numerous sliding pitch changes and long-vowel combinations, e.g. "cheeu cheeu eeraloo eeraloo" or "chiaee-ruraleeoo". Songs usually descend distinctly in pitch and sound melancholic.
Habitat. Usually found in mature lowland broadleaf evergreen forest (often in lightly or heavily logged sites), and forest edges. Also in tall and stunted kerangas and fire padang, subcoastal peatswamp-forest, mature abandoned *Albizia* plantations, and tall secondary growth in vicinity of original forest. Most sightings from plains level and low slopes, except on Mt Jerai (Kedah), in NW Peninsular Malaysia, where ascends to 1200 m; highest record in Borneo from 1300 m.
Food and Feeding. Feeds on berries and other fruits, also insects. The only specific foraging records are of visits to fig trees: banyans (*Ficus benjamina* or *F. microcarpa*) and 14 of 25 *Ficus* in study at Kerau (Peninsular Malaysia), with mean minimum-diameter fruit size 5·4–15·5 mm. Found in singles or pairs, feeding largely on berries. Forages in lower and middle strata and, less regularly, in canopy; most conspicuous at forest edge. Often visits fruiting trees and shrubs to glean fruits, regularly joining other bulbuls. Also gleans insects from foliage, and sometimes joins mixed foraging flocks.
Breeding. Breeds Mar–Jun in Borneo; recent fledgling found on 7th May in Peninsular Malaysia. Rump feathers raised and puffed out in display. One nest was a small neat cup placed 60 cm above ground in a spiny palm. Clutch 2 eggs; no information on incubation and nestling periods; fledglings fed by adults for at least 10 weeks.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Uncommon to locally fairly common. Extinct in Singapore since 1836 (although recent unconfirmed sightings in watershed forests there). Preference for plains-level forest places this bulbul at risk; it is more reliant on tall lowland forest than are most bulbuls, suggesting that it is far more susceptible to the catastrophic clearance of this habitat in the Sundaic region. Its population should be monitored accordingly. Occurs in a range of important protected areas, including Taman Negara National Park, in Peninsular Malaysia, and Tanjung Puting National Park, in Borneo (Kalimantan).



Bibliography. Collar *et al.* (2001), Danielsen & Heegaard (1995), Davison (1987), Davison & Chew Yen Fook (1996), Dickinson & Dekker (2002b), Dickinson *et al.* (2002b), Duckworth & Kelsh (1998), Fogden (1972), Ford & Davison (1995), Gibson-Hill (1949), Jeyarajasingam & Pearson (1999), Lambert (1989b, 1992), Lekagul & Round (1991), Lim Kim Seng (1994b), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Mitra & Sheldon (1993), Nash & Nash (1988), Riley (1938), Robson (2000), Round (1988), Smythies (1986, 1999), Stattersfield & Capper (2000), Vowles & Vowles (1997), Wells (1990b, 2005), Wilkinson, Dutson & Sheldon (1991).

31. **Blue-wattled Bulbul**

Pycnonotus nieuwenhuisii

French: Bulbul à lunettes bleues **German**: Blaubrillenbülbül **Spanish**: Bulbul Ojiazul
Other common names: Nieuwenhuis's Bulbul

Taxonomy. *Poliolophus Nieuwenhuisii* Finsch, 1901, Upper Kayan River, central Borneo.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Some evidence that this taxon is a hybrid between two Sundaic species, one of which must certainly be *P. atriceps*; the appearance of novel characters (such as, in this case, an enlarged and differently coloured eyering) not unprecedented in pycnonotid hybrids. Nevertheless, the case for hybrid status remains tentative, and this enigmatic form is better maintained as a true species until further details come to light. Two subspecies recognized.
Subspecies and Distribution.
P. n. inexspectatus (Chasen, 1939) – NW Sumatra.
P. n. nieuwenhuisii (Finsch, 1901) – N & C Borneo (Brunei, Kalimantan).

Descriptive notes. 18 cm. Nominate race has head dark grey-brown to blackish, with vaguely hooded effect; cheeks and forehead washed greenish-olive; mantle rich olive-green, loose and plush feathering of lower back banded darker at base (showing as dark bars when ruffled), rump paler green-grey; wings and tail dark greyish-brown, broadly fringed olive-green on remiges and rectrices, latter with dark brown subterminal band and small whitish tips; chin and throat dark grey-brown to blackish, merging with dark olive of breast, this in turn merging with pale greenish-yellow of belly and vent; iris warm brown, conspicuous pale fleshy blue eyelids; bill black; legs plumbeous. Sexes alike. Juvenile undescribed. Race *inexspectatus* is slightly brighter and paler, marginally greener and less greyish on upperparts, paler yellow on underparts, with head less blackish, more grey, dark throat contrasting less sharply with breast, iris red, edges of eyering pale blue, bill and legs black. Voice. Unknown; "harsh but quiet notes" thought to be made by this bulbul in Brunei.
Habitat. Insufficient data. Sumatran specimen was taken in low shrubbery on a river island, at 700 m; the Bornean one in tall primary evergreen forest at 610 m, and reported at all levels in same habitat, down to 60 m in N (Brunei). Given the paucity of records, very few conclusions can be drawn regarding the ecology of this species.
Food and Feeding. Insufficient data. In Brunei, seen while feeding with other bulbuls (including *P. melanoleucos* and *P. atriceps*) on fruiting trees, including *Macaranga aetheadenia*. In Sumatra, the single specimen perched near (but not directly associating with) large numbers of *P. atriceps* gathered at fruiting shrubs.
Breeding. No information.
Movements. Presumably resident; perhaps some movements in response to food supplies.
Status and Conservation. Not globally threatened. Not evaluated. Restricted-range species: present in the Bornean Mountains EBA and Sumatra and Peninsular Malaysia EBA. Extremely rare: only two specimens known, and very few observations. After the Sumatran specimen (*inexspectatus*) was taken, the collector spent several days in combing the area for a second individual, but failed to encounter one; in Borneo, the site of discovery of nominate race was revisited after several years, but no further individuals were found. Only subsequent information stems from recent reports from Kuala Belalong, in Batu Apoi Forest Reserve (Brunei). Although this taxon was previously listed as globally threatened, it was recently removed from consideration because of the belief that it is probably a hybrid; until this theory is proven, however, it seems premature to erase all trace of it. Should it be found to be a valid species, it would certainly qualify for inclusion in either the Data-deficient or Critical categories. Primary objective is to determine whether it is a true species; to achieve this aim, renewed searches of likely habitat should be conducted, focusing on regions near the specimen localities, and Batu Apoi Forest Reserve.

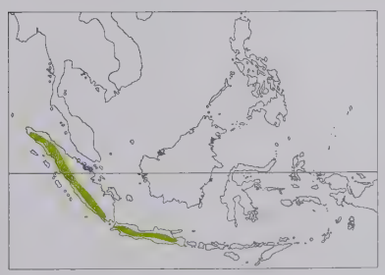
32. Yellow-wattled Bulbul

Pycnonotus urostictus

French: Bulbul à lunettes jaunes **German**: Gelbbrillenbülbül **Spanish**: Bulbul Ojigualdo

Taxonomy. *Brachypus urostictus* Salvadori, 1870, Luzon, Philippine Islands.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species may merit separation at genus level. Racial affiliation of birds recently recorded on Negros uncertain; tentatively included in race *atricaudatus*, but further study needed. Five subspecies recognized.
Subspecies and Distribution.
P. u. ilokensis Rand & Rabor, 1967 – N Philippines (N Luzon).
P. u. urostictus (Salvadori, 1870) – C & S Luzon, Polillo and Catanduanes.
P. u. atricaudatus Parkes, 1967 – Samar, Biliran, Leyte, Panaon, Bohol and Negros.
P. u. philippensis (Hachisuka, 1934) – Dinagat, Siargao, Bucas and Mindanao (except Zamboanga Peninsula).
P. u. basilanicus (Steere, 1890) – W Mindanao (Zamboanga Peninsula) and Basilan.



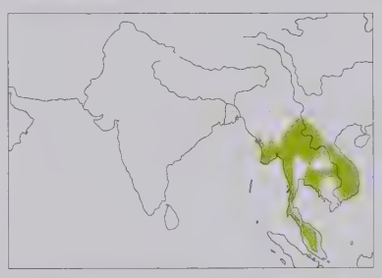
Descriptive notes. 19 cm; male 21–28 g, female 22–26 g. Medium-sized, dull brown bulbul with strongly rounded tail, elongated crest feathers often raised. Nominate race has crown brownish-grey, browner lores, cheeks and neck; upperparts mid-brown, tinged green; central back feathers with black terminal spots, lateral back feathers blackish-brown and broadly and conspicuously tipped white (this feature often concealed); wings dark brown, flight-feathers fringed olive-green; tail brownish-olive, darker distally, narrowly but conspicuously tipped white; throat and underparts pale brownish-grey, becoming whitish on belly and undertail-coverts; iris brown, bare fleshy eyelids chrome-yellow; bill black to dark horn; legs greyish-brown. Sexes alike. Juvenile undescribed. Race *ilokensis* has underparts darker, bill larger, white rectrix tips less extensive; *atricaudatus* has rectrices much blacker, with white tips more extensive, especially on central pair; *philippensis* has large white tail tips as previous, but paler underparts, especially breast; *basilanicus* differs from last in having more olive back, white extending farther into breast. Voice. In general highly vocal. Variable call a loud musical trisyllabic whistle (easily imitated), "wee-a-weeeee" or "wee-eeee-ee", each phrase lasting c.1 second, and given every 4–5 seconds; also a longer, more complicated series of whistles ending in "wee-eeee-ee", and other high-pitched squeaky whistles.
Habitat. Forest edge, open woods, second growth in lowlands, to 1000 m; tends to avoid intact forest.
Food and Feeding. Poorly known. Singles, pairs or small (family?) parties forage mainly on fruit.
Breeding. Breeding recorded in Mar, Apr and Aug; birds with enlarged gonads in May on Samar. Nest cup-shaped; usual clutch 3 eggs. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally fairly common. Able to persist in quite highly fragmented habitats. Occurs in several protected areas, including Rajah Sikatuna National Park, on Bohol.
Bibliography. Brooks *et al.* (1996), Delacour & Mayr (1946), Dickinson & Dekker (2002b), Dickinson *et al.* (1991), duPont (1971), Gilliard (1950), Goodman & Gonzales (1990), Hornskov (1996), Kennedy *et al.* (2000), Parkes (1967), Rand & Rabor (1959b, 1960).

33. Orange-spotted Bulbul

Pycnonotus bimaculatus

French: Bulbul bimaculé **German**: Goldzügelbülbül **Spanish**: Bulbul Bimaculado

Taxonomy. *Turdus bimaculatus* Horsfield, 1821, Java.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. This species may merit separation at genus level. As the type material originates from C (not E) Java, the name *barat* is a junior synonym of the nominate; the name *tenggerensis* must therefore be restored for the E Java race. Three subspecies recognized.
Subspecies and Distribution.
P. b. snouckaerti Siebers, 1928 – NW Sumatra.
P. b. bimaculatus (Horsfield, 1821) – SW Sumatra and W & C Java.
P. b. tenggerensis (van Oort, 1911) – E Java.



Descriptive notes. 20 cm. Dark-coloured, active, conspicuous uncrested bulbul with rounded tail. Nominate race has crown blackish-brown, lightly fringed greyish; head mostly dark, blackest on lores and centre of forehead, with bright orange supraloral tuft of short bristle-like feathers, a smaller yellow-orange spot over eye; large ear-covert patch pale yellow with greenish tinge; upperparts plain brown; wings dark brown, prominently fringed bright olive on flight-feathers; tail dark brown, feathers fringed bright olive, outer ones tipped white; throat and upper breast dark brown, becoming mottled on lower breast; belly creamy white, vent and undertail-coverts bright yellow; iris red-brown or dark brown; bill black; legs black or dark grey. Sexes alike. Juvenile is duller, with dull brown iris. Race *snouckaerti* has lower breast and belly grey-brown (paler on mid-belly), bill relatively small; *tenggerensis* has smaller supraloral tuft, ear-covert patch mottled dark brown, duller green wing fringing. Voice. Noisy, giving variety of loud, harsh songs, including "toc-toc-toc-toroc" and loud clear "chewlk-chewlk-chewlk", or "chuk-chuk-chooh-chewlewlewlew". Sings often.
Habitat. Edges of primary forest, tall second growth, scrub and elfin forest near summit of mountains; in N Sumatra, used thick secondary vegetation between cultivation, and ventured into freshly burnt swidden clearings. Nests usually found in primary or secondary forest, or at edges and in shrubby clearings. From 800 m to 3000 m.
Food and Feeding. Essentially a frugivore; stomachs of birds from N Sumatra contained fruit, including "red peppers" (*Capsicum*), and smaller proportion of insects, including coleopterans and orthopterans. Visits berry-laden trees and shrubs, including blueberries (*Vaccinium*), in lower and middle storeys.
Breeding. Breeds throughout year; records from Java show that nesting occurs in all months, with peak in May. Nest a robustly built, cup-shaped structure, similar to that of congeners, placed 1–5 m above ground in tree or shrub. Clutch 2 eggs, sometimes 3; no information on incubation and fledging periods.
Movements. Resident. In non-breeding season, larger aggregations form locally, some of these gathering to roost communally.
Status and Conservation. Not globally threatened. Restricted-range species: present in Sumatra and Peninsular Malaysia EBA and Java and Bali Forests EBA. Locally common; uncommon in N Sumatra. Prefers high-altitude forests, which are relatively secure, and tolerates highly degraded habitats, suggesting that it is not at any immediate risk. Large populations survive within Gunung Gede-Pangrango National Park, in Java, and Kerinci-Seblat National Park, in Sumatra. Some trapping for cagebird trade.
Bibliography. Andrew (1985), Becking (1989), Büttikofer (1887), Chasen & Hoogerwerf (1941), Dickinson & Dekker (2002b), Fischer (1999), Hellebrekers & Hoogerwerf (1967), Hoogerwerf (1949a), MacKinnon (1988), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Mees (1996), Robinson & Kloss (1920), Sargeant (1997), Stattersfield *et al.* (1998), Tilford (2000), Tobias (1995), Tobias & Phelps (1994).

34. Stripe-throated Bulbul

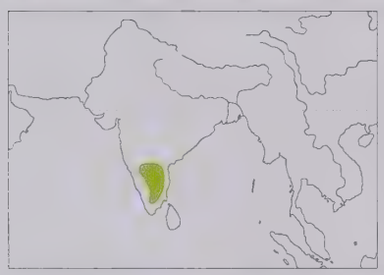
Pycnonotus finlaysoni

French: Bulbul de Finlayson **German**: Streifenkehlbülbül **Spanish**: Bulbul de Finlayson
Other common names: Striped-throated/Streak-throated Bulbul

Taxonomy. *Pycnonotus Finlaysoni* Strickland, 1844, "probably from some of the Malasian [*sic*] islands"; error = Melaka, south-west Peninsular Malaysia.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species may be rather distantly related to the "*P. capensis* complex" and the "*P. cafer* complex". Race *davisoni* differs morphologically and possibly vocally from others; merits further study to assess its taxonomic status. Three subspecies recognized.
Subspecies and Distribution.
P. f. davisoni (Hume, 1875) – S & E Myanmar (Arakan S to R Sittang).
P. f. eous Riley, 1940 – S China (S Yunnan), Thailand and Indochina.
P. f. finlaysoni Strickland, 1844 – S Myanmar (Tenasserim S from R Sittang), S Thailand and Peninsular Malaysia.

Descriptive notes. 19–20 cm; 24–32 g. Medium-sized, dull-coloured, lively bulbul. Nominate race has dark brown lores, sometimes with tiny red supraloral spot; rest of face including ear-coverts, forecrown, chin and throat dark olive-brown with bright yellow centres and shaft streaks; rest of cap to back dull olive-brown with greyish cast, especially on upper neck, where shaft streaks ashy; rump and uppertail-coverts slightly lighter, warmer brown; upperwing similar, with bright olive-green outer webs of primaries forming panel on closed wing; yellow underwing-coverts show at carpal joint; tail olive-green with brown shafts and brighter yellowish-green fringes on feather bases, outermost feathers (at least T5 and T4) with narrow whitish margins at tips; breast greyish with narrow whitish streaks, lower breast and upper belly murky white, central belly to undertail-coverts pale lemon-yellow, occasionally with hint of ochraceous; flanks uniform olive-brown, sometimes with olivaceous tinge; iris dark red-brown; bill dusky black; legs blackish-brown or dark plumbeous. Sexes alike. Juvenile has crown, upperparts and breast paler and browner, no yellow streaks on forecrown and throat, white shaft lines on breast less prominent, belly to undertail-coverts only faintly yellow, iris duller and greyer. Race *eous* is slightly brighter, above and below, than nominate; *davisoni* lacks obvious yellow streaks on forecrown and ear-coverts, has smaller throat streaks, greener crown and rump, rather darker rest of upperparts, breast and flanks, and whitish or brownish-white eyes. Voice. Song a throaty, variable, measured sequence of loud crisp notes, transcribed as "whit-chu which-ic" or "whit whit-tu-iwhit-whitu'-tu"; sometimes resembles song of *P. plumosus* in sound quality and pattern, e.g. "kwik kwok kwo", a hard "pikwik", and rather rich "pik kwok, chikerik, pik wik wok".
Habitat. Secondary growth, scrub, open areas, edges and clearings in broadleaf evergreen, mixed deciduous, evergreen forest and strand (including casuarina) woodland. Also found along forested riverbanks, at roadsides, and in dense young regrowth (e.g. *Eupatrium*), coastal scrub, heavily degraded forest, low and patchy secondary growth around grazing grounds, paddylands, shifting cultivation, tea plantations, rubber plantations, and overgrown gardens. Generally avoids intact forest and dry dipterocarp forest. Lowlands, locally to 1300 m, and recorded to 1770 m in Peninsular Malaysia.
Food and Feeding. A generalist. Diet mainly berries and other fruit, including figs (banyans and *Ficus trichocarpa*, fruit diameter 15·5 mm), *Macaranga tanarius*, and the fleshy aril of *Acacia mangium* seeds; also catches many insects. Usually encountered singly or in pairs; no more than five seen together (thus probably family groups). Frequents middle and lower storeys, gathering to feed in fruiting trees and shrubs with other bulbuls. Sometimes gathers at termite (Isoptera) swarms

On following pages: 35. Yellow-throated Bulbul (*Pycnonotus xantholaemus*); 36. Yellow-eared Bulbul (*Pycnonotus penicillatus*); 37. Flavescent Bulbul (*Pycnonotus flavescens*); 38. White-browed Bulbul (*Pycnonotus luteolus*); 39. Yellow-vented Bulbul (*Pycnonotus goiavier*); 40. Olive-winged Bulbul (*Pycnonotus plumosus*); 41. Streak-eared Bulbul (*Pycnonotus blanfordi*); 42. Cream-vented Bulbul (*Pycnonotus simplex*); 43. Asian Red-eyed Bulbul (*Pycnonotus brunneus*); 44. Spectacled Bulbul (*Pycnonotus erythropthalmos*).



to feed on flying adults, and regularly drops to the ground to feed. Frequently makes aerial sallies after moths (Lepidoptera), termites and other insects, sometimes pursuing them for long distances.
Breeding. Usually Feb–Sept. Nest an open cup-shaped structure c. 6 cm in diameter, rather deep and strongly woven (but virtually see-through), often composed of dry grasses bound with fine creeper stems (often including rhizomes of the climbing fern *Drymoglossum piloselloides*), lined with slender fibres and grasses, with fragments of dead leaves incorporated into outer wall for camouflage, usually placed in upright fork of small leafy bush (e.g. *Melastoma*) or sapling, often isolated in clearing or at roadside etc.; other recorded sites are on branch of forest tree leaning over road, in creepers, and in low clump of spiny stemless palm on grazing ground; nests in Myanmar, Thailand and Peninsular Malaysia 0·5–6 m above ground, but typically towards lower end of this range (often less then 1 m up). Clutch 2–3 eggs, apparently 2 in Peninsular Malaysia; no information on incubation and fledging periods; both pair-members tend fledglings.
Movements. Resident, subject to some minor movements.
Status and Conservation. Not globally threatened. Locally common, at least in N Thailand, S Laos and Malaysia; rare in S China. Current status in Myanmar unclear; was previously not uncommon around Yangon and the Irrawaddy delta, and very common in lowlands of Tenasserim, where once thought to be the commonest bulbul. Given this species' preference for edge habitats and degraded forests, it is unlikely ever to face any serious threat of extinction. Occurs in several protected areas, eg Taman Negara National Park, in Peninsular Malaysia.
Bibliography. Armstrong (1876), Cheng Tsohsin (1987), Daltry & Momberg (2000), Deignan (1945), Delacour (1943), Dickinson & Dekker (2002b), Duckworth, Salter & Khounboline (1999), Ford & Davison (1995), Frith (1981a, 1981b), Gibson-Hill (1949), Gyldenstolpe (1913, 1916), Harington (1909b), Hopwood (1919), Hume & Davison (1878), Jeyarajasingam & Pearson (1999), Lambert (1989b), Lekagul & Round (1991), MacKinnon & Phillipps (2000), Madoc (1976), Medway & Wells (1976), Meyer de Schauensee (1984), Muhammad Afiq Aliudin (2000), Oates (1877, 1878), Oustalet (1903), Riley (1938), Robson (2000), Robson *et al.* (1993b), Smythies (1986), Stanford (1935), Stepanyan (1995), Thewlis *et al.* (1996), Ticehurst (1933), Wells (2005).

35. Yellow-throated Bulbul

Pycnonotus xantholaemus

French: Bulbul à menton jaune **German**: Goldkehlbülbül **Spanish**: Bulbul Gorgigualdo
Other common names: Yellow-eared Bulbul

Taxonomy. *Brachypus xantholaemus* Jerdon, 1845, Eastern Ghats west of Nellore, India.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. This is a rather aberrant species, with no obvious close relative; its generic placement requires further study. Monotypic.
Distribution. S India: S Deccan plateau in E Karnataka, S Andhra Pradesh and N Tamil Nadu.

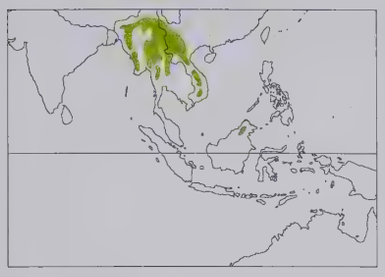
Descriptive notes. 20 cm. A medium-sized, rather silvery, pallid, unobtrusive bulbul. Crown, nape, cheeks, ear-coverts and side of neck are yellowish-olive, mantle, back and scapulars to uppertail-coverts pale grey; upperwings greyish-brown, flight-feathers and wing-coverts edged yellowish-green; rectrices greyish, darkening on distal third, edged yellowish-green, tipped off-white or yellowish; chin and throat strikingly pure yellow, contrasting with grey breast; belly and flanks whitish-grey, vent and undertail-coverts bright pale yellow; iris brown or orange-brown; bill and legs black. Sexes alike. Juvenile has browner breast. VOICE. Song a rich, low, burbling, warbling series, individual notes very quick, at first rising and then falling in pitch, then more constant; reminiscent of *P. luteolus* song, but more deliberate, clearer, harder and airier, and incorporating many more sweet notes. Frequently given call a very brief disyllabic chickle, "teetle-lerp" or "tleep-tillurp", simple compared with calls of congeners; slightly nasal "rhid-tu-tu" also reported, perhaps a different interpretation of same call.
Habitat. Usually found on rocky wooded hillsides and isolated hillocks at 600–1300 m. Frequents slopes with tall shrubs and boulders, thorn-scrub and moist deciduous woodland, often with dense *Lantana* and *Ziziphus*.
Food and Feeding. Diet berries, also insects. Berries include especially those from shrubs such as *Erythroxylon* and *Scutia*, also from other shrubs and trees such as *Lantana camara* (exotic), *Solanum indicum*, *Ziziphus*, *Ficus benghalensis*, *F. nervosa*, *F. montana*, *Canthium dicoccum* and *Phyllanthus reticulata*. Studies at one site suggested that main fruit intake comprised *Solanum indicum* (61%), *Ficus benghalensis* (22%), *Santalum* (11%) and *Ziziphus* (6%). Insects eaten include e.g. caterpillars, picked from ground, branches and leaves, and others such as winged termites (Isoptera) and dragonflies (Odonata), caught during aerial sallies. Skulking but restless; moves alone, in pairs, or in small (family?) groups of up to six individuals, occasionally in mixed flocks, through trees and understorey. Sometimes sits in the open on a rock.
Breeding. Breeds May–Jul. Nest built by female, in one case taking 8 days, in another only 3 days, a large, untidy, clumsy structure (apparently unlike neater nests of most bulbuls), one was constructed from loosely placed coarse twigs and grasses, bound together by cobwebs, lined with fine fibres, sited low down and sheltered by overhanging bush; one was low in dwarf date palm (*Phoenix humilis*), another close to ground in fork of sparse bush, and a third actually on ground (unusual site for a bulbul). Clutch 2–3 eggs, laid on consecutive days; incubation by only one of pair, presumably female; one clutch apparently took 20 days to hatch (this period suspiciously long, requires verification), after which female brooded chicks for a further 7 days, and both parents fed young, which left nest 13 days after hatching.
Movements. Resident.
Status and Conservation. VULNERABLE. Restricted-range species: confined to the Southern Deccan Plateau Secondary Area. Common at some sites, but extremely local. One old record from Kerala; may occur in Orissa, but no confirmed records. Probably declining, as suitable habitat is being cleared in many areas, or being removed to make way for quarries, grazing land and agricultural expansion. Collection of wood for fuel an additional threat. Present in very few protected areas, but does occur within Mudumalai and Sri Venkateshwara National Parks. Further surveys should attempt to clarify the range of this species, and all key sites should be afforded official protection.
Bibliography. Ali (1969, 1996), Ali & Ripley (1996), Allen (1908), Butchart & Stattersfield (2004), Chaitra *et al.* (2000), Collar *et al.* (2001), Dewar (1905), Dickinson *et al.* (2002b), Gee (1995), Grimmett *et al.* (1998), Karanth (1989), Karthikeyan (1995), Nichols (1943–1945), Rasmussen & Anderton (2005), Ripley (1982), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Subramanya & Prasad (1996), Subramanya, Karthikeyan *et al.* (1990), Subramanya, Prasad & Karthikeyan (1995), Venkataswamappa & Chaitra (1999), Whistler & Kinnear (1932).

36. Yellow-eared Bulbul

Pycnonotus penicillatus

French: Bulbul oreillard **German**: Schmuckbülbül **Spanish**: Bulbul Orejudo
Other common names: Yellow-tufted/Ceylon/Sri Lanka Bulbul

Taxonomy. *Pycnonotus penicillatus* Blyth, 1851, Sri Lanka.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species often placed in a monotypic genus, *Kelaartia*, to which it should perhaps be returned. Monotypic.
Distribution. Highlands of Sri Lanka.



Descriptive notes. 20 cm; 36–37 g. A striking, rotund bulbul. Crown, lores, cheeks, forehead, eyestripe and moustachial stripe are black; head adorned with bristly yellow tufts to rear of eye, both above and below, and whitish postorbital spot; distinctive white streaks beginning at base of upper mandible form upright plumes ("horns") above eye; hindneck to uppertail-coverts olive-green, this colour extending onto upperwing-coverts; inner webs of flight-feathers and rectrices blackish-brown, the latter washed olive-green, outer webs strongly olive-green; chin and upper throat white, becoming bright yellow on lower throat, rest of underparts deeper and duller, more olivaceous yellow; underside of tail feathers tipped yellowish; brightness of greens and yellow in plumage variable; iris orange-brown or reddish-brown; bill black; legs dark bluish-grey. Sexes alike. Juvenile has head feathers edged whitish, legs grey-brown. VOICE. Often calls when flying between trees; main vocalization an even-tempo, energetic series of 2–7 identical, explosive, ringing notes, "Swink!-Swink!-Swink!". Also brief sputtery chatter, and low "crr crr" in alarm.
Habitat. Forest and adjacent wooded farms, gardens and regrowth, in mid-canopy, thickets and dense undergrowth. Middle to high altitudes, generally 900–2000 m; absent from lowlands.
Food and Feeding. Feeds on fruit. Gathers in small flocks at fruiting trees, often accompanying mixed-species flocks. Fairly shy; generally keeps to dense undergrowth and forest borders. Usually no higher than mid-storey, but ascends to canopy to feast on major fruit sources, gathering at such places with other frugivorous species such as thrushes (*Turdus*) and barbets (*Megalaima*).
Breeding. Feb–May and Aug–Oct. Nest a fairly substantial cup-shaped structure, made from moss, with some leaf fragments, pieces of dry grass (including "elephant grass"), plant stems and rootlets, lined with fine ferns, rootlets, midribs of decayed leaves or fern stems (usually either black or reddish-brown); placed 3–5 m up (sometimes as low as 1 m) in tree or shrub, usually in upright fork, cluster of twigs, or intersecting branches in denser foliage at top of sapling, often over stream or at forest edge. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Sri Lanka EBA. Abundant in Central Province of Sri Lanka. Not at any immediate risk, but small size of its range means that its status requires monitoring. Forest in Sri Lanka is suffering clearance for agricultural expansion, logging and urbanization, and the situation may deteriorate in future. Occurs in a range of protected areas, including Horton Plains National Park, Hakgala Strict Nature Reserve and Peak Wilderness Sanctuary.
Bibliography. Ali & Ripley (1996), Butchart & Stattersfield (2004), Butler (1896), Collar *et al.* (2001), Dickinson *et al.* (2002b), Grimmett *et al.* (1998), Harrison (1999), Henry (1998a), Hoffmann (1998), Lamsfuss (1998), Lewis (1898), Ranawana & Bambaradeniya (1998), Rasmussen & Anderton (2005), Ripley (1982), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

37. Flavescent Bulbul

Pycnonotus flavescens

French: Bulbul flavescent **German**: Gelbwangenbülbül **Spanish**: Bulbul Amarillento
Other common names: Blyth's Bulbul, Round-tailed Green Bulbul; Pale-faced Bulbul (*leucops*)

Taxonomy. *P[ycnonotus]. flavescens* Blyth, 1845, hills between Sandoway and Pyè, Arakan Yoma, west Myanmar.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Nominate race previously separated in genus *Xanthixus* or *Xanthiscus*, and *leucops* initially described in a monotypic genus, *Oreoctistes*; all races currently included within this species are clearly congeneric, but their placement in present genus is debatable. Race *leucops* is geographically remote from others, differs vocally and morphologically (differences far exceed those between all other races), and is a prime candidate for elevation to species rank. Validity of *vividus* and *sordidus* questionable, as individual variation renders both these and nominate virtually indistinguishable in large series. Putative race *pallens* (Assam, in NE India) is inseparable from nominate. Further research on vocal, behavioural and genetic differences between populations required. Four subspecies provisionally recognized.
Subspecies and Distribution.
P. f. flavescens Blyth, 1845 – NE India (S Assam, Meghalaya, Nagaland, Lushai Hills, also reported NE Arunachal), NE Bangladesh (recent record from Sylhet) and W & SW Myanmar (including Arakan Hills).
P. f. vividus (Stuart Baker, 1917) – S China (W & S Yunnan), N & E Myanmar, NW Thailand (S to Kaeng Krachan National Park), N & C Laos and N & C Vietnam.
P. f. sordidus (Robinson & Kloss, 1919) – S Laos and S Vietnam (including Da Lat plateau).
P. f. leucops (Sharpe, 1888) – N Borneo (Mt Kinabalu S to Gunung Mulu and Gunung Murud, and Gunung Lunjut).
Descriptive notes. 21·5–22 cm (mainland races), 17·5–19 cm (*leucops*); 27–35 g. A medium-large, drab, relatively retiring bulbul with fairly stout bill, rather long and heavy tail, crown feathers often raised to form odd conical crest. Nominate race has crown dark brownish-grey with whitish scaling (in fresh plumage, more uniform dull brown when worn), short white preocular supercilium over dusky brown loral spot, greyish ear-coverts; mantle, back, scapulars, rump and uppertail-coverts dull olive-brown, suffused with stronger greenish or yellowish tint in fresh plumage; wings

mid-brown, more olive-brown on outer webs, with brighter and yellower fringing on primaries (usually forming distinct panel); tail dull olive-brown, feathers brighter and yellower at outer fringe, outermost pair with narrow pale tips; chin and throat pale (sometimes washed fulvous, sometimes whitish); breast pale yellowish-brown, variably streaked darker grey brown (usually indistinct), lower belly and undertail-coverts yellow; iris brown to deep reddish-brown; bill black; legs blackish-brown to dark reddish-brown. Sexes alike. Juvenile has forehead and crown uniform olivaceous brown, head generally more yellowish, less prominent supercilium, also more uniformly and warmer brown upperparts, slight rusty fringing on wing feathers, brownish throat and breast without streaked appearance, paler yellow vent, brownish bill. Race *vividus* is slightly darker than nominate on upperparts and flanks, with yellower underparts, sometimes to throat; *sordidus* is darker and less olivaceous above, generally dark grey below, whitish on throat and yellow on vent; *leucops* is smaller, has greyish-brown crown, white supercilium, lores and cheeks contrasting with blackish iris, pale throat, greyish-brown and vaguely streaked breast, deep yellow undertail-coverts (more restricted than nominate but brighter, showing as golden patch in flight), normally grey base of lower mandible. Voice. Less noisy than many bulbuls, but does sing fairly regularly from exposed perch. Main song a crowing chuckle of 3–6 notes, rising and then falling, "brzk, bzeek, zink-zenk-zink", first 2 notes buzzy and deliberate, the rest clearer, shorter and hurriedly tumbled, or more sprightly, evenly spaced version, "jhoi, bwiki-bwiki-bwik", more even in pitch, notes guttural but somewhat musical; often combines two song phrases without a pause; variants include lengthened or shortened phrases, and a series with similar pattern but entirely of harsh buzzes. Calls include short, strident, sputtering, rasping buzzes, e.g. "brzzk, brzzk", strung together as prolonged unmusical chattering and sometimes as an even rattle. Race *leucops* said to give short, quiet, simple, repetitive song (apparently different in tone from nominate) during which wings sometimes lifted over back; also, noisy churring or purring alarm, often repeated in rolling sequence, and short double alarm call.

Habitat. Open forest, edge, second growth, scrub, mossy forest; avoids intact forest. In tall bushes and thickets in hill forest edges, often around pines (*Pinus*); on high ridges, found in dense bushes in *Imperata* grassland, stunted trees, pines and old abandoned clearings, and scrub near villages. Hills and mountains, usually 800–2100 m, ranging down to 450 m in winter and sometimes ascending to 3500 m. In Borneo (race *leucops*), inhabits tall bushes, thickets and clearings in forested hills (900–3500 m); usually in canopy or borders of montane forest, including shrubby growth above tree-line.

Food and Feeding. Feeds on berries and invertebrates, apparently principally the latter. In Borneo (race *leucops*) eats mainly fruit, e.g. wild raspberries (*Rubus*), small figs (*Ficus*) and *Mallotus*. In singles, pairs or, more often, small groups; forms flocks of up to 30 individuals in winter. Usually forages at middle levels, but regularly from low bushes to high treetops; rarely or never descends to ground. Often shy and quiet, hidden inside bushes and trees, but may be demonstrative; raises crest feathers when excited. Bornean race usually seen singly or in pairs, and reported as venturing in mornings above tree-line on Mt Kinabalu, to feed on berries in alpine heathlands.

Breeding. Mar–Jul. Nest a shallow cup, neatly and firmly made, built in c. 6 days (in Myanmar), in NE India constructed with black fern roots, grass, twigs and tendrils of climbing plants, interwoven with cobwebs, sometimes with leaves, and lined internally with fine grass; placed 0–3 m up (usually at low end of this range) in fork, or between several upright twigs or stems, in bush or large clump of grass. Clutch 2–3 eggs in Indian Subcontinent; no information on incubation and nestling periods. Nests sometimes parasitized by Jacobin Cuckoo (*Clamator jacobinus*).

Movements. Resident; some downslope movement in cold season.

Status and Conservation. Not globally threatened. Locally abundant throughout much of its range; uncommon at edges of mainland range. Abundant in Myanmar in Chin Hills, Karen Hills and Southern Shan States, and the commonest bulbul above 1000 m in Bhamo district; common in N Thailand; rare in S China. Very few recent records from NE India, where it seems generally scarce in all accessible localities; described in older literature as locally common in hilly parts, such as Khasi Hills, N Cachar Hills, etc. Rare and local (probably only an irregular visitor) in Bangladesh, only one recent record (Sylhet); presumably occurs in Chittagong, but no specimens traced. Race *leucops* occurs in Mount Kinabalu National Park, and is locally common along N Bornean mountain range; first recorded in Kalimantan in 1993, at Gunung Lunjut, in Kayan Mentarang National Park. As this species occupies montane, non-forested habitats, it is considered to be at little risk.

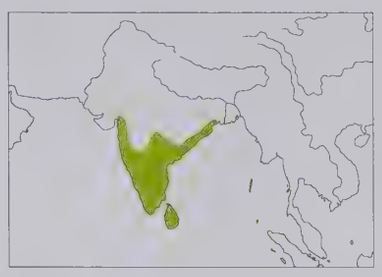
38. White-browed Bulbul

Pycnonotus luteolus

French: Bulbul à sourcils blancs **German**: Weißbrauenbülbül **Spanish**: Bulbul Cejiblanco

Taxonomy. *Haematornis luteolus* Lesson, 1841, Mumbai, India.



Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species forms a superspecies with *P. goiavier*; affinities to other members of genus remain to be clarified. Proposed race *flavirictus* (Tamil Nadu, in S India) considered indistinguishable from nominate. Two subspecies recognized.

Subspecies and Distribution.

P. l. luteolus (Lesson, 1841) – peninsular India (Gujarat, Madhya Pradesh and S West Bengal S to Tamil Nadu); possibly also in Dry Zone of Sri Lanka.

P. l. insulae Whistler & Kinnear, 1932 – Sri Lanka (with possible exception of Dry Zone).

Descriptive notes. 20 cm; 28–43 g. A dingy olive, unkempt, bulky, relatively inconspicuous bulbul with quite short, decurved bill. Nominate has grey-brown crown, whitish forehead, broad frosty white supercilium extending beyond eye, whitish subocular crescent, fine whitish to grey-brown streaks on ear-coverts, narrow dark eyestripe; usually 3–4 slender filoplumes protruding from nape (difficult to see in field); neck to uppertail-coverts olivaceous brown with dull greenish feather edges; wings and

tail similar, with brightest and palest fringing on remiges and rectrices; chin yellowish-white, throat whitish, thin blackish moustachial stripe, and short broad yellow submoustachial stripe; breast pale greyish-olive, merging into yellowish-white on belly, vent yellow; iris variable, usually with reddish tint (thus, dark brown, rusty, dull red or blood-red); bill blackish; legs greyish-black. Sexes alike. Juvenile is duller and browner (less olive-green tinge) above, lacks nuchal filoplumes, supercilium less distinct, ear-coverts unstreaked, fringes of wing feathers rustier, paler below, chin tinged yellow, iris duller. Race *insulae* is slightly smaller and darker than nominate. Voice. Heard more often than seen. Song a long, loud, ebullient, cacophonous flurry that starts with a few hard hesitant notes, then erupts into bubbling, spluttering, rapid chatter of paired staccato notes; shorter, slower versions also given. Song includes some mimicry of e.g. drongos (*Dicrurus*), leafbirds (*Chloropsis*) and others. Calls include song fragments, e.g. "wheek-wheek woo", the notes of emphatic sharp tone of song but well spaced; also a rasping "churr".

Habitat. Open and largely cultivated habitats. Occurs in dry woodland edge, second growth, scrub country and dense thorny thickets (fond of *Lantana* scrub and *Euphorbia* thickets), also gardens and hedges; in Sri Lanka often abundant in variety of man-modified habitats, including cinnamon plantations. Avoids intact forest and humid areas. Lowlands, to c.1300 m in India and to c.1000 m in Sri Lanka.

Food and Feeding. Bulk of diet comprises fruit and berries; small amount of invertebrates consumed, including spiders (Araneae) and a range of insects. Berries and other fruits seem to be more important than insects in nestling diet. Recorded as feeding on wide variety of plant types, including *Lantana*, *Ziziphus oenoplia*, *Mimusops*, *Streblus*, and various figs (e.g. *Ficus banghalensis*, *F. microcarpa*, *F. religiosa*, *F. infectoria*). In S India (Point Calimere, in Tamil Nadu), visited many fruiting trees and shrubs (*Pachygone*, *Tinospora*, *Capparis*, *Cretaeva*, *Flacourtia*, *Hugonia*, *Glycosmis*, *Toddalia*, *Ochna*, *Azadirachta*, *Walsura*, *Olax*, *Cansjera*, *Pleurostylia*, *Salacia*, *Scutia*, *Ziziphus*, *Cissus*, *Allophyllus*, *Lepisanthes*, *Lannea*, *Syzygium*, *Memecylon*, *Coccinia*, *Trichosanthes*, *Opuntia*, *Benkara*, *Canthium*, *Ixora*, *Pavetta*, *Manilkara*, *Diospyros*, *Jasminum*, *Azima*, *Salvadora*, *Carissa*, *Carmona*, *Cordia*, *Ehretia*, *Solanum*, *Premna*, *Cassytha*, *Viscum*, *Breynia*, *Drypetes*, *Phyllanthus*, *Securinegra*, *Asparagus*, *Phoenix*). Also visits flowers (e.g. *Lantana*, *Erythrina*, *Salmalia*) to feed on nectar; in some cases, whole flowers are eaten (e.g. *Tabernaemontana divaricata*, *Argyreia campanulata*). Noisy and restless, usually in pairs, but often skulking, keeping to dry, dense thickets, and rarely perching in open. Rarely descends to ground.

Breeding. Mainly Mar–Sept, but nests found in all months; usually Aug–Mar in S India (Tamil Nadu), but variable, depending on environmental factors and fruiting seasons; Dec–Jun, with most nests in Apr–May, in W Sri Lanka; multi-brooded. Nest an unlined, flimsy, almost oval structure (smaller and less cup-shaped than that of *P. cafer*) made of thin twigs, grass stems or rootlets, lined with fine grasses; in Tamil Nadu, dry hanging roots of the arboreal plant *Tinospora cordifolia* often used as nest material, grass very rarely used (unlike nests of "*P. cafer* complex"); placed usually less than 1·5 m up (sometimes to 4 m), attached by cobwebs or other material (e.g. wool) to fork in bush (e.g. *Lantana*) or small tree, preferentially in thorny bush (in Tamil Nadu most often *Xeromphis spinosa*, followed by *Gymnosporia emarginata*). Clutch 2 eggs, rarely 3–4; incubation period 11 days (Tamil Nadu); nestling period 9–11 days, usually 10 days. Of 114 eggs laid in Tamil Nadu, 13·2% survived to fledging; nest predators were snakes, mongooses (*Herpestes*), coucals (*Centropus*) and blue-magpies (*Cissa*).

Movements. Resident.

Status and Conservation. Not globally threatened. Abundant in much of peninsular India, occurring wherever there is vegetation; absent from humid areas, e.g. moist woods of Western Ghats. Abundant, and one of the commonest and most widely distributed bird species, in Sri Lanka. Preference for cleared areas and tolerance of man-modified environments suggest that this species does not face any threat. Important as an active seed-disperser for many plant species, e.g. in Tamil Nadu. Also performs role as a pollinating agent; conversely, sometimes consumes whole flowers, thereby preventing pollination.

Bibliography. Ali (1932, 1969), Ali & Ripley (1996), Ali & Whistler (1933), Balasubramanian (1996), Ball (1874, 1876, 1878), Barnes (1889), Betham (1897), Brown (1923), Butler, A.L. (1896), Butler, E.A. (1881), Dewar (1905), Dickinson *et al.* (2002b), Fairbank (1877), Ferguson & Bourdillon (1903–1904), Grimmett *et al.* (1998), Harrison (1999), Henry (1998a), Jones *et al.* (1998), Lainer (1999), Law (1936b), Legge (1983), Lewis (1898), Neelakantan (1954), Rasmussen & Anderton (2005), Ripley (1982), Ripley *et al.* (1988), Saha & Dasgupta (1992), Santharam (1997), Siromoney (1963), Vijayan (1980), Whistler & Kinnear (1932), Zacharias & Gaston (1993, 1999).

39. Yellow-vented Bulbul

Pycnonotus goiavier

French: Bulbul goiavier **German**: Augenstreifbülbül **Spanish**: Bulbul Culiamarillo

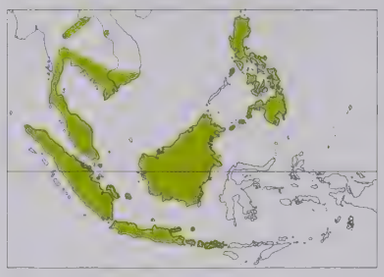
Taxonomy. *Muscicapa* (*Goiavier*) Scopoli, 1786, Manila, Luzon, Philippines.

Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species forms a superspecies with *P. luteolus*; affinities to other members of genus remain to be clarified. Proposed race *personatus* (Sumatra) considered indistinguishable from *analis*; similarly, *karimuniensis* (Karimunjawa I, N of Java) merged with *gourdini*. Six subspecies provisionally recognized.

Subspecies and Distribution.

P. g. jambu Deignan, 1955 – S Myanmar (Tenasserim S from 12·5° N), C & S Thailand, C Laos, S Cambodia and S Vietnam.

P. g. analis (Horsfield, 1821) – Peninsular Malaysia, Sumatra (including Riau and Lingga Archipelagos, Bangka, Belitung), Java (including Kangean Is), Bali, Lombok and Sumbawa.



P. g. gourdini G. R. Gray, 1847 – Borneo (including Maratua I, off E coast) and Karimunjawa I (N of Java).

P. g. goiavier (Scopoli, 1786) – N & C Philippines from Luzon, Polillo Is and Mindoro S, including most smaller islands, to Panay, Guimaras, Negros and Masbate.

P. g. samarensis Rand & Rabor, 1960 – C Philippines (Ticao, Samar, Biliran, Buad, Cebu, Olango, Camotes, Leyte, Bohol).

P. g. suluensis Mearns, 1909 – S Philippines, from Dinagat, Nipa and Camiguin Sur S to Mindanao (including several offshire islets), Basilan and Sulu Archipelago (East Bolod and West Bolod S to Sanga Sanga and Bongao).

Introduced in S Sulawesi around Ujung Pandang (*analis*) and, recently, on Buton I (presumed same race).

Descriptive notes. 19–20·5 cm; 24–37 g. Medium-sized, noisy, conspicuous bulbul with stubby, erectile crest. Nominate race has broad supercilium, crown side, cheeks and throat white, contrasting with dark brown forehead, ear-coverts and coronal stripe (including crest), and blackish loral stripe and ring around eye; neck to back mid-brown with olive-brown fringing, rump and uppertail-coverts olive-brown; upperwings brown, outer webs of primary coverts and flight-feathers edged ashy brown; tail warm dark olive-brown with narrow ash-brown fringing, broader at tip; breast and belly whitish with vague brownish streaking, central belly white, vent and undertail-coverts yellow; iris brown to bright reddish-brown; bill blackish; legs very dark greyish-black. Sexes alike. Juvenile has grey, indistinct supercilium, paler and browner crown, duskier lores and face, warmer brown upperparts and wing-feather fringes, pale grey and lacking obvious streaking below, undertail-coverts paler and duller, bill paler and browner. Race *jambu* has upperparts warmer, more ferruginous, than nominate, underparts sullied slightly browner, ear-coverts whitish, vent and undertail-coverts deeper yellow; *analis* is duller and paler above, with paler abdomen, duller yellow vent; *gourdini* has supercilium off-white (clouded with brown), less fringing on upperparts (more uniform), darker flanks, heavier squamations on breast; *samarensis* is slightly smaller than nominate, with heavier streaks on breast, darker flanks, more blackish crown and ear-coverts; *suluensis* is smaller, with slightly paler crown, distinctly paler ear-coverts. Voice. Song a choppy musical stream of notes, varied and difficult to transcribe. Dawn song relatively simple, e.g. gurgling "trikutruk-trikutruk-trikutruk", jauntier "trikutrik trikutrik trikutrik" ("trik" syllables stressed), "troik-troik-troik-troik" (in flight), jaunty "tidli'tidlu-tidli'tidlu-tidli'tidlu" ("tid" syllables stressed), also stuttering jumble of "trik" and "troik" notes, e.g. "ke-ke-ke-trik ke-ke-troik", speeding up into bubbling call with random extra notes added; day song tends to be longer, quicker, more bubbling, e.g. "key-diddle-diddle-do, key-diddle-diddle-do", "trik-trikatrottle trik-trikatrottle trik-trikatrottle trik-trikatrottle (-trik)", "rellibo-rellibo-rellibo-rellibo, rellibo-rih", or "chook chook trroiku-trroiku-trroiku-trroiku". Pair-members sometimes duet, one giving bubbling song, the other joining in with string of emphatic "treek" notes. Calls with bubbling "chic-chic-chic", and sharp "chwich-chwich", also bubbling "tiddloo-tiddloo-tiddloo" or "tid-liu, tid-liu, tid-liu"; partners often call together, raising wings above back as they do so. Alarm often a sharp, usually 3-note "chiop chop-chop" (e.g. at presence of intruder near nest or fledglings), and common flight call a similar but single, less intense "chep"; fledglings beg with slurred "chio-uck". Voice generally similar to that of *P. cafer*.

Habitat. Coastal scrub, pioneer sea-dune scrub, semi-open banks and shoals of large rivers, scattered bushes and reedbeds, degraded mangroves, second growth, orchards, young plantations (e.g. *Hevea*, *Acacia*, *Pinus*), parks, gardens, cultivation, roadsides, and often in very open situations with only few scattered bushes. Ranges far into suburbia, lives in close proximity with humans. Usually enters forest only where heavily degraded, and then typically only along logging tracks or at old timber-loading sites, but on Deli I and Tinjil I (W Java) occurs only in canopy of mature forest; colonizes new gaps in forest, such as golf courses, very rapidly. The only bulbul in Sundas adapted to oil palm (*Elaeis guineensis*) plantations. Mostly in lowlands; reported at c. 1500 m in Borneo (Mt Kinabalu) and S Philippines (Mt Malindang, on Mindanao), and to 2030 m in Peninsular Malaysia.

Food and Feeding. An opportunist and generalist, with very broad foraging niche. Diet primarily fruits, also seeds and nectar; also large quantities of invertebrates. Wide range of berries, other fruits and seeds, both native and introduced, taken. Fruit eaten includes figs (*Ficus benjamina*, *F. microcarpa*, *F. retusa*, *F. sagittata* and *F. trichocarpa*; fig diameters up to 15·5 mm), *Campnospermum auriculatum*, *Fagraea fragrans*, *Muntingia calabura*, *Glochidion*, *Macaranga*, *Vitex pubescens*, *Melastoma malabathricum*, *Ehretia microphylla*, *Cordia cylindristachya*, *Scaevola sericea*, *Clerodendron*, *Capsicum frutescens*, *Lantana*, *Roystonea regia*, *Passiflora foetida* and *Tetracera indica*; seen to eat ripe *Ptychosperma macarthurii* palm nuts, picked while hanging below inflorescence and swallowed directly; eats ripe flesh of large fruit, e.g. *Artocarpus heterophyllus*, *Carica papaya*, *Eugenia jambos*, *Nephelium lappaceum*, *Musa paradisiaca*, *Psidium guayava*; pecks flesh of ripe mangoes (*Mangifera indica*) while clinging to branches alongside. Noted as eating fleshy arils of *Acacia mangium* and *A. auriculiformis* seeds, arillate seeds of *Dillenia suffruticosa* and *D. excelsa*, and swollen pedicel of cashew (*Anacardium*) seed. Visits flowers to drink nectar, including at blossoms of four-angle bean (*Psophocarpus tetrogonolobus*), *Hibiscus* and *Malvaviscus*; usually functions as pollinator, but sometimes robs *Malvavicus* nectar by piercing corolla base. Invertebrates taken include lepidopterans, termites (Isoptera), ants (Hymentoptera), flies (Diptera), scarab beetles (Scarabaeidae), orthopterans (crickets, grasshoppers), worms; carrion sometimes eaten. Animal food identified as delivered to nestlings included termites, flying ants, orthopterans, mantids, beetles, caterpillars, adult and larval moths and butterflies, intermixed with various seeds (even rice). Harder items (e.g. beetles with tough carapaces) struck vigorously and repeatedly against a branch before being swallowed. Known to eat carrion; one ate dead snails flattened on a road, another removed and ate tail of a dead gecko and attempted to detach a leg. Visits birdtables to take food scraps. Usually encountered singly, in pairs or in parties of up to ten individuals, last-mentioned presumed to be mobile non-breeders. Normally forages fairly low, usually at 0–4 m; often joins congregations of frugivores at fruiting trees, occasionally feeding up to 50 m above ground. Performs aerial-sallies to catch flying insects, darting from exposed perches (including vertically into overhead swarm, somersaulting and gliding back with its capture), and jumping up at them from ground. Also searches foliage and bark (including by peering beneath large leaves) for larvae and other items, and probes bark crevices while clinging to vertical support. Regularly hops about on ground to feed on invertebrates; also picks at squashed or rotting fruit. On one small island, noted as visiting white-sand beaches daily to forage on small flies.

Breeding. Dec–Oct; nests found in all months in tropical regions; multi-brooded. Nest a deep cup, typically of dry grass stems and blades, tendrils, creeper stems and other fibres, enclosed in bamboo and other leaves, leaf skeletons, fern-frond fragments, small twigs, etc., occasionally incorporating small scraps of waste (e.g. paper, some silk), and neatly lined with plant fibres; outside diameter c. 12 cm, depth c. 10 cm, cup 5·6 cm across and 5 cm deep; placed 0·75–3 m above ground, usually in bush or sapling, sometimes in creeper or grass tussock, often in fork in small garden bush, hedge, exotic conifer, palm-frond axil, bamboo twig axil, trailing creeper or scrambling fern, among other sites; often breeds opportunistically in household pot-plants (including in hanging flowerpot), and other man-modified situations (balcony, verandah, etc.); nest sometimes used twice in same season, sometimes three times in succession. Clutch 2–4 eggs, usually 2, laid on consecutive days; incubation, solely by female, starting from second egg (but in one case the two eggs of a clutch hatched one week apart), incubation period 12–13 days; both pair-members tend chicks, both carry away faecal sacs, nestling period 10–14 days, mainly 12 days, rarely 10; fledglings cared for by both sexes, feed independently by fourth day, but tended by adults for up to 1 month.

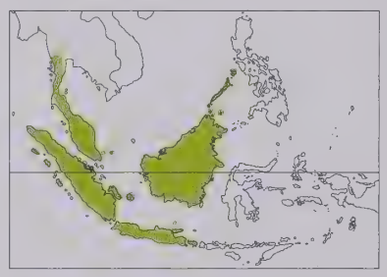
Movements. Resident, subject to some dispersive movements. Non-breeding aggregations form, including large communal roosts (often of several hundreds and possibly thousands of individuals) at traditional locations in reedbeds, scrub and low woodland; some nomadic use of different roosting sites reported.

Status and Conservation. Not globally threatened. Common in SE Asia; first recorded in C Laos, along R Mekong, in 1966. Common in Java, able to tolerate fairly heavy trapping pressure for cagebird trade; common in Sumatra; abundant in lowland and mid-altitude Borneo, and common in cleared lowlands of Philippines. Pre-adapted in a number of ways to have exploited deforestation, and its populations must have exploded in recent centuries; the only bulbul in Sundas adapted to oil palm (*Elaeis guineensis*) plantations, numbers in interior of which rose after introduction of the pollinating weevil *Elaiedobius kamerunicus*. As it is favoured by deforestation and lives commensally with man, it is currently increasing.

Bibliography. van Balgooy (1979), Baltzer (1997), Brooks & Dutson (1997), Chasen & Hoogerwerf (1941), Coates & Bishop (1997), Danielsen & Heegaard (1995), Davison (1997b), Dickinson & Dekker (2002b), Dickinson, Dekker *et al.* (2002b), Dickinson, Kennedy & Parkes (1991), Duckett (1985), Duckworth, Salter & Khounboline (1999), Duckworth, Wilkinson *et al.* (1996), duPont (1971), Edgar (1933), Escott & Holmes (1980), Frith (1981a), Gibson-Hill (1949), Gilliard (1950), Goodman & Gonzales (1990), Grantham (2000), Halliday (1999), Herbert (1923–1926), Holmes & van Balen (1996), Hoogerwerf (1963a), Hoogerwerf & Siccama (1937–1938), Hopwood (1919), Hume (1873b), Hume & Davison (1878), Jenkins *et al.* (1996), Jeyarajasingam & Pearson (1999), Kennedy *et al.* (2000), Lambert (1987), Lekagul & Round (1991), Lever (1987), MacKinnon (1988), MacKinnon & Phillipps (1993), Madoc (1976), van Marle & Voous (1988), McClure (1961, 1964), Medway & Wells (1976), Mees (1986, 1996), Ogilvie-Grant & Whitehead (1898), Purseglove (1957), Rabor (1977), Ramachandran (1982), Rand & Rabor (1960), Rensch (1931), Riley (1938), Ripley & Rabor (1958), Robson (1994, 1996b, 1996c, 2000), Smythies (1957, 1986, 1999), Ward (1969), Wells (1990a, 2005), White & Bruce (1986).

40. Olive-winged Bulbul

Pycnonotus plumosus



French: Bulbul aux ailes olive **German**: Malaienbülbül **Spanish**: Bulbul Aliverde
Other common names: Olive-brown/Large Olive Bulbul

Taxonomy. *P[ycnonotus]. plumosus* Blyth, 1845, Singapore.

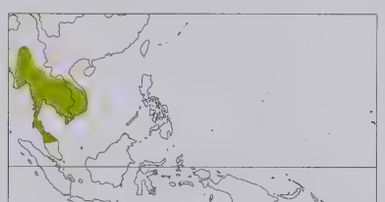
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. Present species previously included in genus *Brachypus*, which possibly merits resurrection; further study required to clarify relationships. Race name *insularis* previously considered invalid (and replaced by new name *hachisukae*), as preoccupied by a race of *Andropadus importunus* (formerly included in expanded present genus). Races *porphyreus*, *hutzi* and *insularis* only dubiously separable; full review required in order to assess their validity. Other described races are *chiroplethis* (Anamba Is), *billitonis* (Belitung) and *sibergi* (Bawean I) all barely distinguishable from nominate, and treated as synonyms of it. Five subspecies provisionally recognized.

Subspecies and Distribution.

P. p. plumosus Blyth, 1845 – S Myanmar (Tenasserim S from 12·5° N), S Thailand, Peninsular Malaysia (including Tinggi I), Singapore, E Sumatra (including Bangka and other associated islands), Java (including Bawean I), Bali and W & S Borneo (including Anamba Is).
P. p. porphyreus Oberholser, 1912 – W Sumatra and islands.
P. p. cinereifrons (Tweeddale, 1878) – W Philippines (Busuanga, Culion, Palawan).
P. p. insularis Chasen & Kloss, 1929 – N Borneo islands and SW Philippines (Cagayan Sulu).
P. p. hutzi Stresemann, 1938 – N & E Borneo.

Descriptive notes. 20–20·5 cm; 24–36 g. Relatively dainty, small-headed, unassuming bulbul. Nominate race has dark brown lores and eyering, grey face, olive-brown ear-coverts with white shaft lines that start below eye; cap dark olive-brown with faintly paler and greyer fringes (distinctly squamate impression in good light); upperparts to uppertail-coverts dark olive-brown, strongly tinged greenish, rump slightly warmer brown; upperwing olive-brown, primaries and secondaries darker, with brighter yellowish-green edging; tail dark olive-green with deep brown shafts and brighter yellowish-green edging; chin and throat whitish with faint greyish-brown tinge; breast olive-brown, faintly infused with ochraceous yellow (faded when worn, giving breast a greyish cast); flanks as breast but darker and browner, belly as throat but with tawny tinge, undertail-coverts light olive-brown with yellowish-buff margins; iris brownish-orange, red or dark red (age-related); bill blackish-brown to dark grey-brown; legs reddish-brown, variably paler to darker. Distinguished from similar *P. blanfordi* by less pronounced whitish streaks on ear-coverts, slightly darker olive wash on chest, yellowish-green (rather than ashy brown) flight-feather edging, dark eye. Sexes alike, male on average slightly larger than female. Juvenile is browner overall, particularly on throat and vent (yellow tones lacking), with less obvious whitish streaks on face, duller flight-feather fringes, browner eyes, also lacks dark patterning on undertail-coverts. Race *porphyreus* has iris orange, yellow or creamy-white (brown in immature); *cinereifrons* has pale greyish fringes and centres on forehead feathers, pale greyish breast, pale greyish-white belly, olivaceous-buff undertail-coverts, duller fringes of remiges and rectrices; *insularis* is very similar to nominate, but slightly larger (although measurements overlap); *hutzi* has slightly darker (less olive) upperparts, slightly greyer (less yellowish) underparts. Voice. Song soft and chirping, with liquid, fruity quality, similar to that of *P. finlaysoni*; common song phrases, among almost infinite variations, transcribed as "quick doc-tor quick", slightly longer and more stressed "quick doc tor quíck doc", or with stuttered components, e.g. "qu-quick doc tor quíck d-doc", "pee-kwod, kapichu-peeku, pee-kwod" or "whip wi-wiu wu-wurri'i"; in Philippines, as "chop wit chu do-de-do-de-du". Calls include throaty "whip-whip" and purring "wrrh wrrh wrrh".

Habitat. Very broad range of habitats, from forest edge and second growth to coastal scrub and mangroves. Scrubby landward fringe of mangrove forest, degraded strand woodland and coastal scrub generally, including paperbark (*Melaleuca*) stands and screw-palm (*Pandanus*) thickets; pioneer/gap-phase trackside and riverside secondary growth at edge of lowland evergreen forest and peatswamp-forest, and where forest heavily degraded; mixed orchard, e.g. under coconut plantings; abandoned rubber (*Hevea*) and other tree plantations, e.g. of teak, pine (*Pinus*) and *Araucaria*, reverting to secondary forest; secluded thickets in parkland. Not normally in parks or gardens, but will venture far out into scrubby grassland. Usually in lowlands, but on slopes to c. 500 m, rarely to 800 m, in parts of Peninsular Malaysia.



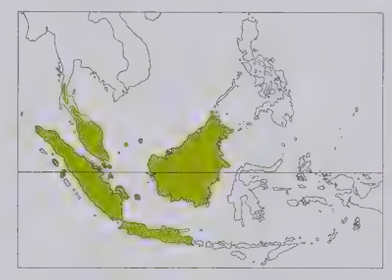
Food and Feeding. Generalist, consuming berries, other fruits, invertebrates. Diverse diet includes figs (*Ficus microcarpa*, *F. trichocarpa*), small fruit of *Gynotroches axillaris* and *Campnospermum auriculatum* (Anacardiaceae), and the aril of *Acacia mangium* seeds; also *Dillenia excelsa*, *D. suffruticosa*. Consumes various arthropods, including beetles (Coleoptera) and orthopterans, and even freshwater crabs. Usually seen singly or in pairs, sometimes in small family parties; usually low down. Often joins other bulbuls at fruiting trees.
Breeding. Jan–Sept; almost through year in tropical localities. Record of three apparent adults (one brooding, flanked by two perched) at one nest suggested presence of helper, but proof of co-operative breeding lacking. Nest, sometimes built by two adults, is a deep, open cup, with external diameter c. 7 cm, loosely constructed from dead leaves and fine creeper stems, often decorated on outside with bamboo leaves, lined with fine fibres and a little grass, placed 1·5–13 m above ground (mostly towards lower end of range) usually in a bush or sapling, commonly in the shrub layer of abandoned rubber plantations, once in an *Araucaria* plantation; reported sites include hollowed top of Nipa (*Nypa*) palm frond stub, stemless forest-edge bertam palm (*Eugeissona tristis*), deep in clump of screw-palm, in scrambling resam ferns, in fork in low rhododendron (*Melastoma malabathricum*), in fork of rubber tree. Clutch 2 eggs; no information available on incubation and fledging periods; fledged broods of one and two young recorded, fledglings tended at least sometimes by two adults.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally abundant throughout much of range. Ability to tolerate broad range of degraded and man-modified habitats suggests that this species is not likely to face any future risk of extinction.
Bibliography. Bartlett (1895), Berwick (1952), Büttikofer (1887), Chasen (1935), Corlett & Lucas (1989), Danielsen & Heegaard (1995), Davison (1987), Davison & Chew Yen Fook (1996), Dickinson, Dekker *et al.* (2002b), Dickinson, Kennedy & Parkes (1991), Duckworth & Kelsh (1998), duPont (1971), Dymond (1994), Edgar (1933), Fogden (1972), Ford & Davison (1995), Gibson-Hill (1949), Harrisson (1964), Holmes (1994), Hoogerwerf (1965), Hume & Davison (1878), Jenkins *et al.* (1996), Jeyarajasingam & Pearson (1999), Kemp (2000), Kennedy *et al.* (2000), Lambert (1989b), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Phillipps (1993), Madoc (1976), Mann (1991), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Oberholser (1917b), Peh & Ling Ong (2002), Riley (1938), Robson (2000), Smythies (1957, 1986, 1999), Tilford (2000), Vowles & Vowles (1997), Wells (1990a, 1990b, 2005).

41. Streak-eared Bulbul

Pycnonotus blanfordi

French: Bulbul de Blanford **German**: Blanfordbülbül **Spanish**: Bulbul de Blanford
Other common names: Blanford's (Olive) Bulbul

Taxonomy. *Pycnonotus blanfordi* Jerdon, 1862, Thayetmyo, south Myanmar.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. This species may warrant placement in a separate genus, alongside some other bulbuls of SE Asia and Sundaic region. Proposed race *robinsoni* (Malay Peninsula) is indistinguishable from, and merged with *conradi*. Birds reported from N & C Laos not subspecifically identified. Two subspecies recognized.
Subspecies and Distribution.
P. b. blanfordi Jerdon, 1862 – W, C, E and S Myanmar (apparently including Arakan).
P. b. conradi (Finsch, 1873) – Thailand, N & C Peninsular Malaysia (N Kedah, Kelantan), S Laos, Cambodia, C & S Vietnam (in C & S Annam, Cochinchina).
Also (subspecies undetermined) N & C Laos.



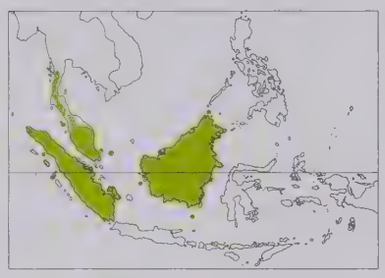
Descriptive notes. 17·5–20 cm; 28–36 g. Medium-sized, nondescript, brownish bulbul. Nominate has dark brown lores, dull white lower face washed greyish-brown; ear-coverts and area below eye pale brown with prominent white shaft streaks; cap and upperparts to rump dull earth-brown, crown feathers slightly lengthened and with darker brown centres, uppertail-coverts slightly lighter, pale creamy; upperwings as mantle; primary coverts and flight-feathers slightly darker brown, outer webs fringed olive-brown; tail olive-brown with greenish tinge; chin and upper throat whitish, merging into greyish on lower throat, and light brownish-grey on breast and upper flanks; middle belly to undertail-coverts uniform pale tawny buff; iris pale grey in male (female possibly greyish-brown), eyelids plumbeous; bill blackish-brown, sometimes pale pinkish-grey base of lower mandible; legs slaty brown, claws blackish. Best distinguished from confusingly similar *P. plumosus* by voice, iris colour, lack of greenish edging of flight-feathers, pale creamy undertail-coverts. Sexes alike. Juvenile has iris light greyish-brown, bill horny brown, feet and toes plumbeous, claws pinkish. Race *conradi* has distinctly yellowish-tinged vent, and underparts often yellower than in nominate. Voice. Harsh "chu-chu-chu" or rasping "which-which-which" when foraging, and sometimes in flight. Also more piping "brink-brink-brink"; voice lacks the rich, fruity quality of *P. plumosus* and *P. finlaysoni* song.
Habitat. Scrub (inland and coastal), bamboo, open mixed deciduous woodland, semi-desert, cultivation, parkland, gardens, urban areas, tracksides and clearings. Favoured habitats overlap with those of *P. plumosus*, but occurs in rather more open sites. Lowlands to 900 m.
Food and Feeding. Diet fairly broad, includes both fruit and insects. Fledglings fed with berries and many insects, including termites (Isoptera), caterpillars and orthopterans. Most often encountered singly, in pairs, or in family-sized parties, but record of group of up to twelve individuals aerial-foraging. Usually arboreal; also forages aerially and in sallies from perches. Also drops to the ground to catch insects; apparently lifts or flips leaves and small stones to seek items underneath.
Breeding. Recorded Mar–Sept in Myanmar, Mar–Jul in N Thailand and Jan–Sept in S, and Feb–Jul in Peninsular Malaysia; multi-brooded. Nest construction in one case took 4 days; nest relatively small and flimsy, a firm but loosely constructed open cup made from small twigs, leaf stalks, grass and fibres (e.g. coconut fibres), with plenty of spider webs attached to outside; often placed less than 2 m above ground, sometimes up to 5 m, in branch fork of bush or small tree (e.g. *Croton*, *Ziziphus jujuba*), or lodged in creeper, insecurely attached and prone to dislodgement in high winds. Clutch 2–3 eggs; incubation mostly by female, male at least sometimes incubates for short stints, period (from laying of last egg) 11–12 days; hatching often asynchronous, but eggs laid on successive days hatched together; nestlings tended by both sexes, both remove faecal sacs, also observed to swallow faeces of well-developed chicks, nestling period 10 days; fledged broods of 1–3 observed. Chicks often preyed on by crows (Corvidae) in Thailand.
Movements. Resident.
Status and Conservation. Not globally threatened. Common to abundant in N & C Thailand and S Laos. The commonest lowland bulbul in much of Myanmar; common throughout valleys of R Irrawaddy and R Sittang, often occurring in built-up areas and around major cities (e.g. Shwebo, Mandalay, Yangon etc.). Given this species' propensity to live at high densities in highly man-modified environments, it is unlikely to to be at any immediate risk.
Bibliography. Daltry & Momberg (2000), Deignan (1940a, 1945), Delacour & Jabouille (1931), Dickinson *et al.* (2002b), Duckworth, Salter & Khounboline (1999), Frith (1981a, 1981b), Gibson-Hill (1949), Harington (1909b), Herbert (1923–1926), Hopwood (1912), Hume (1875), Jeyarajasingam & Pearson (1999), Lekagul & Round (1991), Macdonald (1906), Madoc (1950, 1976), Mears & Oates (1907), Medway & Wells (1976), Riley (1938), Robinson & Kloss (1919a), Robson (2000), Robson *et al.* (1993b), Smythies (1986), Stanford (1935), Strange (2002), Thewlis *et al.* (1996), Ticehurst (1932, 1933), Wells (2005).

42. Cream-vented Bulbul

Pycnonotus simplex

French: Bulbul aux yeux blancs **German**: Weißaugenbülbül **Spanish**: Bulbul Ojiblanco
Other common names: White-eyed (Brown) Bulbul

Taxonomy. *Picnonotus* [*sic*] *simplex* Lesson, 1839, Sumatra.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. This species may warrant placement in a separate genus, alongside some other bulbuls of SE Asia and Sundaic region. Wide individual variation found throughout range. Race *halizonus* barely distinguishable, and may not be valid; described race *axanthizus* (Natuna Is) synonymized with that taxon. In addition, proposed races *chloeoides* (NW Sumatra), *perplexus* (N Borneo) and *oblitus* (Bangka, Belitung and W Borneo) all poorly differentiated, or described on basis of eye-colour morphs; treated as junior synonyms of nominate. Three subspecies recognized.
Subspecies and Distribution.
P. s. simplex Lesson, 1839 – S Thailand and Peninsular Malaysia S, including Riau and Lingga Archipelagos, to Sumatra (including Bangka, Batu, Belitung, Nias I), and Borneo (including Balambangan I).
P. s. prillwitzi Hartert, 1902 – Java.
P. s. halizonus Oberholser, 1917 – Anambas Is and Natuna Is.



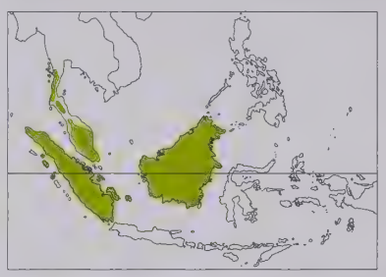
Descriptive notes. 18 cm. Medium-small, nondescript, noisy, conspicuous bulbul. Nominate race has head (except throat) and upperparts uniform dark warm olive-brown, upperwings with brighter fringing on secondaries; tail dark olive-brown with slight rufous tinge, darker than uppertail-coverts; chin and throat whitish with slight creamy tinge; breast pale brown with cream feather fringing, shading browner at side and on flanks; belly to undertail-coverts pale creamy white with slight yellow tinge, palest on tail-coverts, slight greyish-brown wash on breast and flanks; iris strikingly white or yellowish-white, but in Borneo and some Sumatran satellite islands most have red iris; bill black; legs brown. Distinguished from similar *P. brunneus* and *P. erythropthalmos* by colder brown upperparts, somewhat cleaner, creamy-whitish underparts. Sexes alike. Juvenile has crown, upperparts and wing-feather fringes warmer brown; iris grey-brown, slowly changing to pale orange or warm brown, then pale yellowish to white, bill dark horn-brown, feet brownish-pink. Race *prillwitzi* has lighter upperparts, yellower underparts; *halizonus* is virtually identical to nominate, but supposedly has fractionally longer and heavier bill. Voice. Short, emphatic song phrases, "quik chop" and "quik-plik chop", and slightly longer "beequik, pee dee kew"; harsh and repetitive call notes; also subdued quavering "whi-whi-whi-whi-whi", interspersed with low "pru-pru, prrr" and "prr-pru".
Habitat. Broadleaf evergreen forest (mature and disturbed), edges, secondary growth, peatswamp-forest, and heath-forest; one of very few bird species regular in the extreme *Baeckia/Gluta* heath-scrub of the Gunung Keriong plateau, in Peninsular Malaysia. In standardized mist-netting efforts in Negeri Sembilan (Peninsular Malaysia), more than twice as many individuals trapped in 25-year-old regenerating forest as in nearby mature forest, but only 16 % retrapped in regenerating growth (compared with 36 % in mature growth), implying different usage of habitat. From lowlands to 1300 m.
Food and Feeding. Fruit; also insects, including cockroaches (Blattodea) and caterpillars. Regularly forages on mass-produced small fruit (e.g. *Fagraea fragrans*) or figs, including banyans (*Ficus microcarpa*, *F. sumatrana*), and 11 of 25 *Ficus* species (mean minimum fruit-diameter in range 5·4–15·5 mm) in study at Kerau, in Peninsular Malaysia. Recorded as feeding on fruit of *Callicarpa* and *Gmelina* in Borneo. Usually encountered singly or in pairs; several individuals may converge at a fruit source, but no evidence that larger groups formed. Gathers at fruiting trees and shrubs with other bulbuls. Regularly joins mixed-species foraging flocks of insectivores. Usually seen in lower and middle storeys along forest trails, especially in more open areas, but also ascends to canopy.
Breeding. Feb–Oct. Builds cup-shaped nest, using small twigs, creeper tendrils and rootlets; one individual in Borneo gathered cobweb into a ball and flew off with it, suggesting that cobweb sometimes used as binding for outer layers of nest; usually in thick undergrowth, either in upright fork or attached to vertical stems. Clutch 2 eggs; no information available on incubation and nestling periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common or very common across much of range. Has presumably suffered rapid decline in lowland Sumatra and Java, where forest has been cleared at an astonishing rate over recent decades. Because this species requires fairly well-developed forested habitats, it is more at risk than are many open-country bulbuls: its use of foothill and submontane heath-like habitats, however, suggests that it is unlikely to become seriously threatened.
Bibliography. Chasen & Kloss (1929), Danielsen & Heegaard (1995), Davison (1987), Deignan (1954), Dickinson & Dekker (2002b), Dickinson *et al.* (2002b), Dymond (1994), Fogden M.P.L. (1966), Ford & Davison (1995), Gibson-Hill (1949, 1950), Gregory-Smith (1997a), Holmes (1994, 1996), Hoogerwerf (1966), Jenkins *et al.* (1996), Jeyarajasingam & Pearson (1999), Kidd (1978), Lambert (1989b), Lekagul & Round (1991), Lim Boo Liat (1965), MacKinnon (1988), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Mayr (1938), McClure (1966), Medway & Wells (1976), Mees (1986), Oberholser (1912, 1932), Peh & Ling Ong (2002), Rajathurai (1996), Riley (1938), Robson (2000), Smythies (1957, 1999), Vowles & Vowles (1997), Wells (1976, 1990a, 1990b, 2005).

43. Asian Red-eyed Bulbul

Pycnonotus brunneus

French: Bulbul aux yeux rouges **German**: Rotaugenbülbül **Spanish**: Bulbul Ojirrojo
Other common names: Red-eyed (Brown) Bulbul, Brown Bulbul

Taxonomy. [*Pycnonotus*] *brunneus* Blyth, 1845, Melaka, Peninsular Malaysia.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. This species probably warrants placement with *P. erythropthalmos* in a separate genus; both appear rather distantly related to the "*P. capensis* complex" and "*P. cafer* complex". Race *zapolius* hardly distinguishable, and perhaps unworthy of taxonomic recognition; form on Tioman I (off E Peninsular Malaysia) previously misidentified as belonging to this race. Described race *zaphaeus* (from Pulau Matasiri, off SE Borneo) indistinguishable from nominate. Two subspecies recognized.
Subspecies and Distribution.
P. b. brunneus Blyth, 1845 – S Myanmar (Tenasserim S of c. 12·5° N), extreme S Thailand, Peninsular Malaysia (including Tioman I), Sumatra (including Banyak, Nias, Batu, probably also Bangka I) and Borneo (including Banggi, Karimata and Larot).
P. b. zapolius Oberholser, 1917 – Anamba Is.



Descriptive notes. 19 cm; 24–37 g. A nondescript bulbul, almost uniformly brown in colour. Nominate has head (except throat) and upperparts warm olive-brown, upperwing with faint lighter and brighter olive fringing on secondaries; flash of tawny underwing usually exposed at carpal joint; tail dark olive brown, outer webs of feathers with dull olive-green fringes (chiefly at bases); chin and throat whitish with distinct tawny tinge; breast to upper belly ashy brown, feathers edged pale buff, shading richer brown at side and on flanks; lower belly as breast but more uniform and paler, undertail-coverts dull tawny-yellow with pale brown shaft marks; iris red, sometimes cream-coloured; bill dark brown to dark reddish-brown, distinctly darker on upper mandible; legs brown or reddish-brown, variably darker or paler. Distinguished from very similar *P. erythropthalmos* mainly by lack of bright eyering, brighter (less grey) crown and mantle, no rufous tinge on rump, browner (less grey) breast. Sexes alike, male on average slightly larger than female. Juvenile has upperparts and wings slightly paler, warmer brown; iris light grey or brownish-grey, later dull orange, bill blackish-horn; legs pinkish-brown. Race *zapolius* is slightly larger than nominate (but extensive overlap), with slightly darker and more greenish upperparts. Voice. Series of high-pitched bubbling notes, the last ones rising sharply, "pri-pri-pri-pri-pri-pit-pit"; also brief trills, twitters, and short strident "chirrup" or "whit-it!".
Habitat. Broadleaf evergreen forest and peatswamp-forest (mature and disturbed), particularly at edges and in secondary growth, often venturing into adjacent scrub; one record from mangrove forest (Langkawi I, off W Peninsular Malaysia). Often occurs in riverside and trackside growth, and occasionally in mature tree plantations, e.g. rubber (*Hevea*), near forest. In standardized mist-netting efforts in Negeri Sembilan (Peninsular Malaysia), 14 individuals trapped in 20-year-old regenerating forest, compared with only one in mature forest. Plains level and slopes generally to c. 450 m, locally higher, to at least 1000 m, even into patches of low *Baeckia* heath-forest in highlands of Peninsular Malaysia.
Food and Feeding. Fruit, including berries, and seeds; also invertebrates. One adult seen to carry a lizard's tail, perhaps for nestlings. Fruit taken includes many figs (*Ficus*), e.g. banyans (*Ficus microcarpa*), *F. sumatrana*, and more than half (in mean minimum fruit-diameter range 5·4–27·4 mm) of 25 *Ficus* species in study at Kerau, in Peninsular Malaysia. Noted as feeding on berries and seeds of *Eurya acuminate*, *Acacia mangium*, *Dillenia suffruticosa*, *Pipturus*, *Licuala paludosa* (a palm), *Macaranga triloba*, *Trema tomentosa*, *Callicarpa albida*, *Gmelina*, and the melastome *Dissochaeta pallida*. Invertebrates in diet include grasshoppers (Orthoptera) and caterpillars; also many other insects, occasionally caught in flight during brief sallies. One individual in Sumatra had eaten a spider (Araneae). Observed as singles, pairs and small family parties; up to five may converge independently on a fruit source, but not known to form groups. At least occasionally joins mixed-species foraging flocks; of 135 individuals encountered at Gombak, in Peninsular Malaysia, 29 (21%) were in mixed-species flocks. Often forages together with *P. atriceps*, *P. erythropthalmos*, *Iole olivacea*, and leafbirds (*Chloropsis*). Forages mostly in lower and middle storeys; less often in canopy.
Breeding. Feb–Oct. Nest a deep open cup, external dimensions 10 cm across and 6·5 cm deep, cup diameter 7 cm and depth 3·6 cm, made of broad leaves, leaf stalks and midribs enclosing layer of dried strips of grass blade, threshed rice heads and some kapok cotton, the cup itself lined with layer of springy black fibres likely (but not confirmed) to have been horsehair fungal hyphae; placed 0·5–5 m up in variety of sites, e.g. leaflet axil of a ginger (Zingiberaceae) in scrub, dense crown of bush in grass-filled clearing or on forested reservoir bank, and tree-crown foliage; one nest on Borneo was 2 m up on jagged top of broken-off sapling. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally fairly common throughout range. Tolerant of fairly severe habitat disturbance, and unlikely to be at risk. Nevertheless, total numbers must have declined in recent decades because so much forest has been lost in lowlands of Sundaic region. Occurs in several protected areas, including Taman Negara National Park, in Peninsular Malaysia, and Bukit Barisan Selatan and Way Kambas National Parks, in Sumatra.
Bibliography. Chasen & Hoogerwerf (1941), Danielsen & Heegaard (1995), Davison (1987, 1997b), Davison & Chew Yen Fook (1996), Dickinson *et al.* (2002b), Dymond (1994), Ford & Davison (1995), Gibson-Hill (1949), Gregory-Smith (1995, 1997a), Holmes (1994, 1996), Hume & Davison (1878), Jenkins *et al.* (1996), Jeyarajasingam & Pearson (1999), Lambert (1989b), Lim Boo Liat (1965), MacKinnon (1988), MacKinnon & Phillipps (1993), van Marle & Voous (1988), McClure (1966, 1967), Medway & Wells (1976), Mees (1986), Oberholser (1917b, 1917c), Rheindt (2004), Riley (1938), Robson (2000), Smythies (1957, 1986, 1999), Vowles & Vowles (1997), Wells (1990b, 2005), Wilkinson, Dutson & Sheldon (1991).

44. Spectacled Bulbul

Pycnonotus erythropthalmos

French: Bulbul oeil-de-feu **German**: Salvadoribülbül **Spanish**: Bulbul de Anteojos
Other common names: Lesser Brown Bulbul

Taxonomy. *I*[*xos*]. *erythropthalmos* Hume, 1878, Pakchan estuary, Myanmar.
Genus as currently constituted probably polyphyletic; in-depth analysis of morphology, voice, behaviour and genetics required to redefine its limits. This species probably warrants placement with *P. brunneus* in a separate genus; both appear rather distantly related to the "*P. capensis* complex" and "*P. cafer* complex". Species name often misspelt as *erythrophthalmos* or *erythropthalmus*. Earlier names for this taxon (*simplex* and *pusillus*) are invalid, as either improperly instated or preoccupied within genus. Form on Borneo has been thought subspecifically distinct, and was initially named *pusillus*, then renamed *salvadorii*, but indistinguishable in larger series from other populations. Three other described races, *cyanochrous*, *isus* and *pammicrus* (all from W Sumatran islands), also treated as junior synonyms. Monotypic.
Distribution. S Myanmar (Tenasserim), S Thailand, Peninsular Malaysia, Sumatra (including Banyak, Nias, Batu, Lingga Archipelago, Bangka, Belitung) and Borneo.

Descriptive notes. 16–18 cm; 16–22 g. Lores, face down to gape, and ear-coverts are olive-brown with greyish cast; rest of cap to back warm olive-brown, rump and uppertail-coverts noticeably more rufescent; upperwings warm olive-brown, tertials and inner secondaries fringed slightly brighter and more rufescent; tail dark brown with faint rufous tinge, feathers fringed at bases with brighter rufous-brown; chin and throat pale smoky grey; breast grey, browner at side and on flanks, infused with pale creamy yellow; belly and undertail-coverts creamy white, tinged tawny; underwing-coverts yellow; iris deep red, orange to yellow-orange eyering, gape yellow-orange; bill blackish; legs dull pinkish-brown. Distinguished from very similar *P. brunneus* mainly by orange eyering (conspicuous at close range), duller and greyer crown and mantle, more rufescent rump and uppertail-coverts, whiter or buffier throat and belly (never tinged brown or olive), greyer breast and upper belly, also slightly smaller size, smaller, more sharply pointed and blacker bill. Sexes alike, female fractionally smaller than male. Juvenile has upperparts and wings slightly paler and warmer brown, iris light brown, grey or red-brown, off-white eyering, browner bill than adult. Voice. Usual song a distinctive, repeated, rather high-pitched mechanical phrase, also described as a hurried, musical jingle, or a "galloping trill", hard to transcribe but sounding like "pip-pippidi", "ke-pippidi" or "wip-wip-wi'i'i'i'i"; also a slower "pi-pi-di", without introductory grace note. Main calls short, rather airy little phrases, e.g. "willy-nilly" or "pippi-dippi", with occasional downswept extra note, "willy-nilly-no".
Habitat. Middle stratum and understorey of mature and regenerating broadleaf evergreen forest, peatswamp-forest, edges, roadsides, riversides, secondary growth, overgrown orchards, mature gardens, mangroves backed by woods; often ventures out into shrubby clearings. On average, prefers slightly less open habitats than those occupied by *P. simplex* and *P. brunneus*. In survey of Khao Nor Chuchi Wildlife Sanctuary, in Thailand, found only in mature forest; in contrast, in standardized mist-netting in Negeri Sembilan, in Peninsular Malaysia, many more trapped in 20-year-old regenerating forest than in nearby mature forest. Plains level and slopes, to recorded upper limit of c. 1000 m.
Food and Feeding. Fruit; some specimens had also consumed whole flowers and buds; a certain amount of insects (including caterpillars) also eaten. Nestling diet consists of both fruit and insects. As most of its forest-dwelling congeners, exploits the mass-produced small fruit of gap-colonizing trees, including *Macaranga*; also takes many figs (*Ficus*), including banyans, and 11 (all in fruit-diameter range 5·4–15·5 mm) of 25 *Ficus* species in study at Kerau, in Peninsular Malaysia. Other species visited include *Acacia mangium*, *Dillenia excelsa*, *Callicarpa albida* and *Gmelina*. Usually encountered singly, or in pairs; occasional single-figure parties may be families groups or individuals converged independently on a food source. Often attends fruiting trees and shrubs, with other bulbuls.
Breeding. Feb–Aug. Nest a deep open cup built of twigs, dead leaves, rootlets and vegetable fibres, lined with fine dry grass; one was 3 m up among crown twigs of sapling in forest clearing, sheltered under a leaf, another low down in thick undergrowth, and another at top of 10-m rubber (*Hevea*) sapling. Clutch 2 eggs; older nestlings fed by one or more adults every 15–20 minutes. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common in most of range; rare in S Myanmar. Generally less common than *P. simplex* and *P. brunneus* (and less often in groups). Extinct in Singapore owing to clearance of much habitat.
Bibliography. Chasen & Hoogerwerf (1941), Chasen & Kloss (1930), Danielsen & Heegaard (1995), Davison & Chew Yen Fook (1996), Dickinson & Dekker (2002b), Dickinson *et al.* (2002b), Dymond (1994), Gibson-Hill (1949), Gregory-Smith (1997a), Holmes (1994, 1996), Hume & Davison (1878), Jenkins *et al.* (1996), Jeyarajasingam & Pearson (1999), Lambert (1989b), Lekagul & Round (1991), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Mayr (1938), Medway & Wells (1976), Mitra & Sheldon (1993), Oberholser (1912), Riley (1938), Robson (2000), Round & Brockelman (1998), Smythies (1957, 1986, 1999), Strange (2002), Vowles & Vowles (1997), Wells (2005).

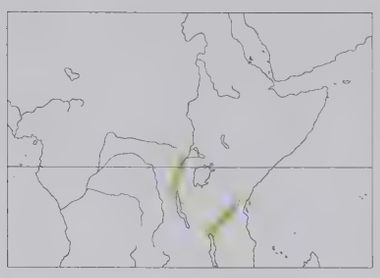
Genus *ANDROPADUS* Swainson, 1831

45. **Cameroon Montane Greenbul**

Andropadus montanus

French: Bulbul concolore **German**: Einfarbbülbül **Spanish**: Bulbul Montano
Other common names: Cameroon (Mountain) Greenbul, Mountain (Little) Greenbul

Taxonomy. *Andropadus montanus* Reichenow, 1892, Buea, 950 m, Mount Cameroon, Cameroon.
Genus formerly submerged in *Pycnonotus*. Has been suggested to form a superspecies with *A. masukuensis*, and in the past considered conspecific, but differs significantly in plumage and voice; also, while recent fieldwork and molecular evidence indicate that latter is more closely related to *A. tephrolaemus*, phylogenetic studies indicate that present species is sister-taxon to both. Monotypic.
Distribution. Extreme SE Nigeria (Mt Gangirwal, Gotel Mts and Obudu Plateau) and W Cameroon (Tchabal Mbabo and Bamenda Highlands S to Mt Cameroon).



Descriptive notes. 17–18 cm; male 30–34 g, female c. 30 g. A medium sized, uniformly plumaged montane greenbul. Head and entire upperparts, including wings and tail, are yellowish olive-green, slightly brighter on rump and uppertail-coverts; lores a little greyer, with inconspicuous, non-contrasting yellowish-olive eyering slightly paler than surrounding feathering; underparts also yellowish olive-green, somewhat brighter yellow on lower breast, belly and undertail-coverts; iris bright red or red-brown; bill black; legs grey or grey-black. Sexes alike, female on average smaller than male. Juvenile little known; probable immature had grey-brown eye and yellowish-grey feet. Voice. Song soft and unobtrusive, a somewhat subdued nasal, husky babble ending with faster, rather cheerful chuckling phrase, "churp-churp-churp-chipurchipurcherr". Calls include low "kerr" or "purr" (easily overlooked) and rapidly repeated nasal "chup".
Habitat. Mid-altitude and, particularly, montane forest, especially forest edge, clearings, secondary regrowth and adjacent scrub. Mainly 1000–2500 m, but recorded to 500 m on slopes of Mt Cameroon in non-breeding season.
Food and Feeding. Fruit, including *Harungana*, *Maesa* and probably *Myrica* and *Schleffera*; also seeds and insects. Usually occurs singly, sometimes in pairs; unobtrusive and shy. Forages generally low down in dense shrub layers, occasionally up to 10 m.
Breeding. Nesting recorded in Cameroon in Mar and May, birds in breeding condition in Jan–Feb and Nov, nest-building in Mar, and juveniles in Feb–Apr. No other information.
Movements. Little information. Probably largely resident, but some evidence of seasonal movements to lower altitudes during non-breeding season.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Cameroon Mountains EBA. Variously scarce to common in different parts of its range. Considered potentially threatened by unsustainable exploitation of timber, uncontrolled burning, and clearance of habitat for agriculture. Occurs in Gashaka-Gumti Reserve, in Nigeria, and in Banyang Mbo Wildlife Sanctuary and Rumpi Hills and Bali-Ngemba Forest Reserves, in Cameroon; other localities from which it is known are not formally protected in any way.
Bibliography. Bannerman (1936, 1953), Borrow & Demey (2001), Bowden (2001), Butchart & Stattersfield (2004), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1998b, 1999, 2000, 2001b), Eisentraut (1963, 1973), Elgood *et al.* (1994), Fishpool & Evans (2001), Fotso (1996), Hall & Moreau (1970), Keith *et al.* (1992), Larison *et al.* (2000), Louette (1981), Mackworth-Praed & Grant (1973), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stuart (1986).

46. **Shelley's Greenbul**

Andropadus masukuensis

French: Bulbul des Masuku **German**: Shelleybülbül **Spanish**: Bulbul de las Masuku
Other common names: Kakamega Greenbul (*kakamegae*)

Taxonomy. *Andropadus masukuensis* Shelley, 1897, Masuku Range, 7000 feet [c. 2140 m], northwest of Lake Nyasa, Malawi.
Genus formerly submerged in *Pycnonotus*. Has been suggested as forming a superspecies with *A. montanus*, and in the past considered conspecific, but differs significantly in plumage and voice. Recent molecular data, however, supporting similarities in vocalizations and aspects of behaviour (including scansorial foraging technique), indicate that it forms a superspecies with *A. tephrolaemus*, with *A. montanus* as sister-taxon to both. Race *kungwensis* originally described under *A. tephrolaemus*, when latter considered conspecific with *A. nigriceps*. Has been proposed that grey-headed races (*kakamegae*, *kungwensis*) and green-headed ones (*roehli*, nominate) represent two incipient species; genetic analyses support close relationship between last two taxa, and available data (although insufficient for proper assessment) reinforce the hypothesis that the relationship with the two other races may be more distant. Four subspecies recognized.
Subspecies and Distribution.
A. m. kakamegae (Sharpe, 1900) – E DRCongo (from SE edge of Ituri S to Mt Kabobo), SW Uganda (Kalinzu, Bwindi), SW Rwanda, W Burundi, W Tanzania (Kigoma) and W Kenya.
A. m. kungwensis (Moreau, 1941) – Kungwe-Mahari Mts, in W Tanzania.
A. m. roehli Reichenow, 1905 – NE, C & SW Tanzania (from South Pare Mts and Usambaras S in Eastern Arc range to Songea and Njombe).
A. m. masukuensis Shelley, 1897 – SW Tanzania (Rungwe, Ukinga) and extreme N Malawi (Misuku Hills).

Descriptive notes. 16·5–17 cm; male 22–28 g, female 20–25 g (*kakamegae*). A medium-sized, montane greenbul with distinctive foraging behaviour. Nominate race has top and side of head olive-green, narrow contrasting white broken eyering, some indistinct darker and paler streaking on ear-coverts; upperparts, including wings and tail, brighter greenish-olive, brightest on rump and uppertail-coverts; throat grey-olive; underparts dull olive-green, paler than upperparts, palest and washed yellow on centre of breast and belly; iris brown to red-brown or chestnut; upper mandible black or dark brown, lower mandible grey, blue-grey or slate; legs slaty blue to blue-grey to grey-green or green. Differs from *A. gracilis* and *A. ansorgei* in larger size, more empahatically grey head (*kakamegae*), more yellow underparts; from *A. milanjensis* in smaller size, duller underparts, less obviously pale-streaked ear-coverts. Sexes alike, female on average smaller thana male. Juvenile resembles adult, but duller above, breast and crown more olive. Race *roehli* has top of head somewhat duller than nominate, eyering wider, side of head greyer, throat grey, underparts more grey-olive; *kakamegae* has grey head, throat also grey, underparts brighter, more yellow-olive, than nominate; *kungwensis* is also grey-headed, top of head dark grey, throat paler grey than face, breast pale grey with greenish wash, greener on belly and flanks. Voice. Relatively little known. Race *roehli* has fairly loud, simple "ke-kew-ke-kew-ke", soft, nasal "kwew, kwa, kwew" and subdued "wit-wit-wit"; nominate has soft, lilting song of c. 8 notes, "chip, wa-da-tee, chee-tu, ti-wew", repeated with little variation; *kakamegae* largely silent.
Habitat. Montane and mid-altitude forest, also gallery forest; 1000–2300 m in DRCongo, 900–2300 in E Africa, 1600–2000 m in Malawi; commonest at 1300–1500 m in Eastern Arc Mts of Tanzania.
Food and Feeding. Arthropods and small fruits. Fruits recorded in diet include *Harungana*, *Maesa*, *Maesopsis*, *Renealmia*, *Trema*, *Urera*. Insects may form up to 90% of diet in wet season, falling to less than 60% in dry season. Usually occurs singly or in pairs, in larger numbers at fruiting trees. Regularly joins mixed parties, more so in dry season, and has been recorded as attending *Dorylus* ant swarms. Unobtrusive, but not particularly shy. Forages at all levels, from ground layer to canopy, most commonly between 4 m and 8 m; tends to forage higher in dry season. Feeds in dense tangles of lianes and shrubs and low thickets (e.g. of *Dracaena* and *Acanthopale*); regularly works over outer edges of foliage for berries and insects. Also has distinctive habit (nominate race, *roehli* and *kakamegae*, at least) of systematically gleaning from bark of large tree trunks and vertical branches and stems, by clinging to them while searching in crevices, behind loose bark, in epiphytic mosses and similar places; regularly does this by starting at base of a large tree, working up it in short hops for 6–10 m, then flying down to base of next tree and repeating process. Also gleans insects from sides and undersurfaces of horizontal branches. Occasionally flicks wings while feeding.
Breeding. Feb and Sept–Nov in DRCongo, in Jan–Feb, Jul–Aug and Oct–Dec in Tanzania, and in Oct–Nov in Malawi; birds in breeding condition in Mar and Oct–Nov in Uganda and in Jun in Kenya. Nest a shallow cup, external diameter 7·5–9 cm, internal diameter 5 cm, made of fibrous material such as vine tendrils, rootlets, flower stalks, veins from skeletonized leaves and moss, unlined or lined with black fibre (possibly *Marasmius* hyphae), placed 1·5–5 m above ground in fork of small sapling. Clutch 1–2 eggs; no information on incubation and nestling periods.
Movements. Largely resident; some movement to lower altitudes during cold/dry seasons recorded in Tanzania (Usambara, at 500 m), and record of an individual at 1250 m in riparian forest in Malawi may represent another instance of such movement.
Status and Conservation. Not globally threatened. Generally fairly common, and even locally abundant. Densities difficult to assess owing to this species' relative lack of vocalizations; in Eastern Arc range of Tanzania, up to c.35 individuals/km² reported in one study and 168 individuals/100 ha in Udzungwa Mts in another. Occurs in several national parks, including Virunga National Park, in DRCongo, Kibira National Park, in Burundi, Bwindi-Impenetrable Forest National Park, in Uganda, and Udzungwa and Mahali Mountain National Parks, in Tanzania; also in numerous forest reserves, including those of Nyungwe, in Rwanda, Kakamega, in Kenya, East and West Usambara and Uluguru Mountains, in Tanzania, and Misuku Hills, in Malawi.
Bibliography. Bennun (1994), Benson & Benson (1977), Britton (1972, 1980), Brown & Britton (1980), Burgess & Mlingwa (2000), Byaruhanga *et al.* (2001), Chapin (1953), Dinesen (1995, 1997), Dowsett (1990), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire (1989), Dowsett-Lemaire & Dowsett (2004), Hall & Moreau (1964, 1970), Jackson & Sclater (1938), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1960, 1963, 1973), Mann (1985), Moyer (1993), Prigogine (1971, 1978, 1984), Romdal (2001), Roy *et al.* (1998), Sclater & Moreau (1932), Stevenson & Fanshawe (2002), Svendsen & Hansen (1995), Turner & Zimmerman (1979), Willis (1983), Zimmerman (1972), Zimmerman *et al.* (1996).

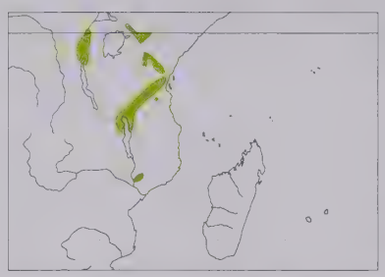
47. **Western Mountain Greenbul**

Andropadus tephrolaemus

French: Bulbul à gorge grise **German**: Bergwaldbülbül **Spanish**: Bulbul Pechioliva
Other common names: Grey-throated Greenbul

Taxonomy. *Trichophorus tephrolaemus* G. R. Gray, 1862, Mt Cameroon, 7000 feet [c. 2140 m], Cameroon.
Genus formerly submerged in *Pycnonotus*. Recent phylogenetic studies indicate that this species forms a superspecies with *A. masukuensis*; the two exhibit some similarities in vocalizations and behaviour (including scansorial foraging technique). Previously thought to form a superspecies with *A. nigriceps*, and often treated as conspecific, but differs in several aspects, including plumage and, especially, voice. Races vary clinally; birds nearer Mt Cameroon (e.g. on Mt Kupé) intermediate between nominate and *bamendae*. Two subspecies recognized.
Subspecies and Distribution.
A. t. tephrolaemus (G. R. Gray, 1862) – extreme SE Nigeria (Mambilla Plateau, Gotel Mts, Obudu Plateau) and W Cameroon (Tchabal Mbabo and Bamenda Highlands S to Rumpi Hills, Bakossi Mts and Mt Kupé).
A. t. bamendae Bannerman, 1923 – SW Cameroon (Mt Cameroon) and Equatorial Guinea (Bioko).

On following pages: 48. Eastern Mountain Greenbul (*Andropadus nigriceps*); 49. Stripe-cheeked Greenbul (*Andropadus milanjensis*); 50. Grey Greenbul (*Andropadus gracilis*); 51. Ansorge's Greenbul (*Andropadus ansorgei*); 52. Plain Greenbul (*Andropadus curvirostris*); 53. Slender-billed Greenbul (*Andropadus gracilirostris*); 54. Yellow-whiskered Greenbul (*Andropadus latirostris*).



Descriptive notes. c. 18 cm; 29–40 g (nominate), 32–47 g (*bamendae*). Medium-sized, distinctive, montane greenbul. Nominate race has head and neck slate-grey, with lores and ill-defined narrow stripe above eye a little darker; contrasting narrow white broken eyering; upperparts, including wings and tail, bright olive-green, brightest on uppertail-coverts; throat and top part of breast pale slaty grey, rest of underparts yellowish-olive, darkest across breast and on flanks, more yellow on belly; iris brown, hazel, red-brown or dark red; bill black; legs greenish, greenish-grey or blue-grey. Sexes alike, female on average smaller than male. Juvenile is duller, head washed olive, underparts darker, eye brown. Race *bamendae* is slightly larger, darker, duller, less yellow, than nominate, with dark olive wash on breast. Voice. Song a monotonous, steady dry series of notes, same form repeated continuously, "whup-wheep-whip-whupchipip" and "whup-weep-whup-wheep-whup-wheep", also faster series of nasal, chirruping notes. Call a nasal, scolding "whee-up" or "dzut-dzuwi", second note upslurred; low nasal "waa" in flight.
Habitat. Mid-altitude and, particularly, montane forest, including clearings, secondary regrowth and adjacent scrub. Occurs at 400–2850 m, but not common below 1000 m; juveniles recorded down to sea-level on Mt Cameroon, but exceptional.
Food and Feeding. Diet mainly fruit, particularly figs (*Ficus*) and *Maesa*; also some insects, including beetles (Coleoptera). Occurs singly, in pairs or in small family groups; large numbers may gather at fruiting trees. Joins mixed-species flocks. Forages at all levels, from low undergrowth to canopy. Gleans insects acrobatically from moss-clad branches, including undersides; also clings to bark of tree trunks, as *A. masukuensis*.
Breeding. Nesting recorded in Nov–Jun and Aug in Cameroon; mainly in dry season, but may breed in all months. Nest a well-knit cup of moss, tendrils, *Usnea* lichen, plant stems and cobwebs, lined with fine grasses and fibres, external diameter 9–9·5 cm, depth 3·5–6·5 cm, internal diameter 6–7·5 cm, cup depth 3–5 cm; placed 1–3 m above ground, slung between slender horizontal shoots or branches by strands of tendrils, moss or *Usnea*, and well concealed in undershrub or tree-fern. Clutch 1–2 eggs; no information on incubation and fledging periods.
Movements. Little information. Probably largely resident; some evidence of seasonal movements to lower altitudes, particularly by juveniles, during non-breeding season.
Status and Conservation. Not globally threatened. Restricted-range species: present in Cameroon Mountains EBA. Generally common, sometimes abundant, across most of its range, except at lower altitudes. Density estimated at 4–5 birds/ha on Mt Oku, in Cameroon. Occurs in Gashaka-Gumti Reserve, in Nigeria, and Banyang Mbo Wildlife Sanctuary, Rumpi Hills Forest Reserve and Bali-Ngemba Forest Reserve, in Cameroon; also in Basilé Peak National Park and Luba Caldera Scientific Reserve, on Bioko. Other localities from which it is known are not formally protected in any way.
Bibliography. Bannerman (1936, 1953), Borrow & Demey (2001), Bowden (2001), Chappuis (1975), Dowsett (1990), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1998b, 2001b), Eisentraut (1963, 1973), Elgood *et al.* (1994), Fishpool & Evans (2001), Forboseh *et al.* (2003), Fotso (1996), Hall & Moreau (1970), Keith *et al.* (1992), Larison *et al.* (2000), Louette (1981), Mackworth-Praed & Grant (1973), Pérez del Val (1996), Roy *et al.* (1998), Serle (1950b, 1954), Stattersfield *et al.* (1998), Stuart (1986).

48. **Eastern Mountain Greenbul**

Andropadus nigriceps

French: Bulbul à tête sombre **German**: Schwarzkappenbülbül **Spanish**: Bulbul Cabecioscuro
Other common names: Olive-breasted Mountain Greenbul; Green-throated/Greenish-throated Greenbul (*chlorigula*)

Taxonomy. *Xenocichla nigriceps* Shelley, 1889, Mount Kilimanjaro, 6000 feet [c. 1830 m], Tanzania.
Genus formerly submerged in *Pycnonotus*. Often treated as forming a superspecies with, or conspecific with, *A. tephrolaemus*, but differs in plumage and, especially, voice; recent studies, however, indicate that latter is more closely allied with *A. masukuensis*, race *kungwensis* of which was originally described under *A. tephrolaemus* (then considered conspecific with present species). Race *chlorigula* sometimes considered a separate species. Phylogenetic analysis suggests that N races (nominate, *kikuyuensis*, *usambarae*) form a clade only rather distantly related to S forms (*chlorigula*, *neumanni*, *fusciceps*) and, further, that relationships within latter group may not be very close; in addition, of the forms tested, the N races appeared to be more closely related to *A. milanjensis* (of race *striifacies*) than to S races of present species, although support for this relationship was not statistically significant. These findings, different from those inferred from morphological studies, have resulted in proposals for elevation of some or, indeed, all races to species level; the case for such treatment, however, not yet proven, and vocal differences between at least some of the races are small; more studies required. Six subspecies recognized.
Subspecies and Distribution.
A. n. kikuyuensis (Sharpe, 1891) – E DRCongo (Ruwenzoris S to Mt Kabobo), SW and SE Uganda, Rwanda, Burundi, and Mt Elgon and C Kenya Highlands.
A. n. nigriceps (Shelley, 1889) – S Kenya (Nguruman) and adjacent N Tanzania (Mt Kilimanjaro and Crater Highlands S to Mbulu and Mt Hanang).
A. n. usambarae (Grote, 1919) – SE Kenya (Taita Hills) and NE Tanzania (S Pare and W Usambara Mts).
A. n. chlorigula (Reichenow, 1899) – EC & S Tanzania (Kiboriani and Nguru Mts S to Iringa, Njombe and Songea).
A. n. neumanni (Hartert, 1922) – E Tanzania (Uluguru Mts).
A. n. fusciceps (Shelley, 1893) – SW Tanzania (Poroto Mts, Rungwe) S to extreme NE Zambia (Mafingas, Makuta and Nyika), NC & SE Malawi (S Viphya Plateau, also Zomba and Mt Mulanje) and WC Mozambique (Mt Namuli).
Descriptive notes. c. 18 cm; male 29–41 g, female 29–32·5 g (*kikuyuensis*). A medium-sized, variably but distinctively patterned montane greenbul. Nominate race has forehead and crown blackish, sharply demarcated lores and side of face (including ear-coverts) dark grey with some wide, contrasting paler streaking, also contrasting dirty white broken eyering; neck dark grey, upperparts, including wings and tail, olive-green, brightest on uppertail-coverts; grey below, paler and washed yellow in middle of belly, flanks washed olive-yellow, undertail-coverts yellow-olive; iris brown, hazel, red-brown or dark red; bill shiny black; legs blue-grey, greenish-grey, greenish or greenish-brown. Differs from *A. milanjensis* mainly in colour and pattern of head. Sexes alike, female on average smaller

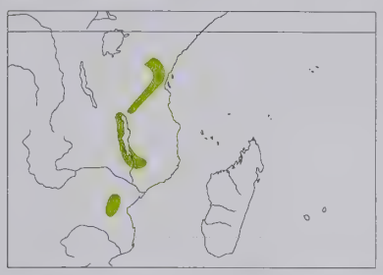
than male. Juvenile is duller, darker overall, eye brown or grey-brown. Race *kikuyuensis* has whole of head, neck and upper mantle slate-grey, except for variable ill-defined darker streak above eyering (indistinct superciliary stripe), fainter darkish line below eye and some lines on ear-coverts, brighter olive-green above, light grey throat and upper breast, rest of underparts bright olive-yellow, brightest on belly; race *usambarae* has top of head as previous, but more distinct narrow black supercilium from above lores to behind eye, narrow ill-defined dark line on rear ear-coverts at junction with olive-green neck side, underparts as nominate; *neumanni* has blackish crown like nominate, but lacks contrasting eyering and paler streaking on side of face; *fusciceps* has crown dull grey, washed olive, black superciliary stripe, little or no pale streaking on ear-coverts, broken white eyering broad, upperparts dull green, underparts dull grey, washed brownish, lower flanks grey-olive, undertail-coverts dull yellowish-olive with mottled appearance (pale tips); *chlorigula* has grey head washed brownish, broken white eyering broad, little or no pale streaking on head side but blackish preocular and postocular areas, chin pale grey, throat olive-yellow, becoming olive-green on breast side, rest of underparts grey, belly centre paler, lower flanks and undertail-coverts yellow-olive, latter appearing mottled (pale feather tips). Voice. Race *chlorigula* has 5-note song, "chip-chop-cho-chilly" (transliterated as "it's not so chilly"), first note short, increasing in volume at end, delivered at c. 10-second intervals; *fusciceps* similar but last 2 notes more extended, "chip-chop-wicho-weeyo", also a shortened phrase, "chop-wi-choda"; call a chattering, repeated "twuk", also "pichu" or "hor-pi-chu". In nominate and *usambarae* at least two types of song reported, one a deliberate "kwo, kwer-kwer, kwee, kwo" (recalling *chlorigula*), other a conversational "kwew-ki-kwew-ki-kwew"; *usambarae* also as "hee-her-hee". Song of *neumanni* "chipchuck, chuck choo-kweeo" (differs only slightly from *chlorigula*); that of *kikuyuensis* (in Rwanda) of two types, a fairly well-defined phrase of 6–8 distinct notes, "jur-jitjur-dajur-jur-jerry", repeated with minor variations and last note upslurred (recalling *nigriceps* and *chlorigula*), and a husky, low, nasal phrase lasting 1–2 seconds, notes all on one pitch, rich in harmonics, and lacking boisterous cheerful quality and distinct phrases of Tanzanian races. Call a loud, rapid, nasal "qwer-qwer-qwer-qwer", alarm in Kenya a short, grating "churr". Situation confused, as it is suspected that some earlier published descriptions of vocalizations now refer to other species.
Habitat. Montane forest of all types, both primary and secondary, including low-canopy forest, riparian forest, as well as montane shrubland, bracken-briar and bamboo. Common in secondary regrowth, edges and clearings and in recently deforested areas. At 1350–3300 m in E Africa and 1500–2450 m in Malawi; some regular wandering down to 700–1000 m, once to 500 m.
Food and Feeding. Fruit, also some flowers and parts of leaves; also arthropods, including beetles (Coleoptera) and spiders (Araneae). Extensive range of fruits taken, over 60 species recorded in Malawi; *Agalaea*, *Coccinia*, *Harungana*, *Ilex*, *Maesa*, *Polyscias*, *Rutidea*, *Schleffera*, *Trema* and *Urera* recorded as eaten in Rwanda, and *Euclea*, *Teclea* and members of Rubiaceae in Tanzania. Found singly, in pairs, or in family groups of up to six individuals; larger numbers may gather in fruiting trees, particularly figs (*Ficus*). Attends doryline ant swarms and joins mixed-species flocks. Conspicuous and inquisitive. A generalist that forages at all levels, from undergrowth to subcanopy. Gleans insects from leaves, tangles, epiphytes, branches etc.; also captures them in short aerial sallies.
Breeding. Recorded Mar–Aug and Oct–Nov (may breed all year, with peak during dry season) in DRCongo; Sept–Mar in E Africa, starting in Kenya Highlands before short rains, continuing through and into succeeding dry period, peak in Feb; Sept–Dec, avoiding coldest, wettest months, in Tanzania; Aug–Nov, i.e. end of dry season/start of rains (peak period of both fruit and insects), in Zambia and Malawi. Monogamous; territorial. Nest a neat cup of moss, tendrils, fine roots and grass stalks, lined with dark hyphae of *Marasmius* fungus, external diameter 13 cm, depth 5·5 cm, internal diameter 7 cm, cup depth 3 cm, built 1–2 m above ground among creepers and undergrowth; mean territory diameter in Malawi 80 m. Clutch 1–3, usually 2; incubation by female only; no information on incubation and fledging periods.
Movements. Mainly sedentary. Some regular downslope movement in at least parts of range, mostly during cool season in Tanzania (Usambaras, Ulugurus); in Malawi (Nyika and Mt Mulanje), recorded down to 700–1000 m, once 500 m, mainly Apr–Aug. For 59 birds ringed on Nyika, greatest recapture distance was 2·5 km, but most moved only 250–500 m.
Status and Conservation. Not globally threatened. Race *chlorigula*, often treated as a full species, a restricted-range taxon: present in Tanzania-Malawi Mountains EBA. Generally common to abundant across its range. Density estimates in Malawi 2–3 pairs/ha in fragmented forest, 1 pair/ha in larger forest blocks (1 pair/2 ha where it competes with *A. milanjensis*). In Eastern Arc mountains of Tanzania, maximum density c. 60 individuals/km². Occurs in numerous national parks, including those of Virunga, in DRCongo, Volcans, in Rwanda, Kibira, in Burundi, Bwindi-Impenetrable Forest, in Uganda, Aberdare and Mount Kenya, in Kenya, Arusha and Udzungwa, in Tanzania, and Nyika, in Malawi, as well as in many forest reserves across its range.
Bibliography. Benson & Benson (1977), Benson *et al.* (1971), Britton (1972, 1980), Brown & Britton (1980), Burgess & Mlingwa (2000), Byaruhanga *et al.* (2001), Chapin (1953), Cordeiro (1994a), Dinesen (1997), Dowsett (1985b, 1990), Dowsett & Dowsett-Lemaire (1984, 1993), Dowsett & Forbes-Watson (1993), Dowsett *et al.* (2004), Dowsett-Lemaire (1989), Dowsett-Lemaire & Dowsett (2004), Friedmann & Loveridge (1937), Fuggles-Couchman (1939), Hall & Moreau (1970), Jackson & Sclater (1938), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1960, 1963), Moreau & Sclater (1938), Prigogine (1971, 1978, 1984), Romdal (2001), Roy *et al.* (1998), Sclater & Moreau (1932), Stattersfield *et al.* (1998), Stevenson & Fanshawe (2002), Svendsen & Hansen (1995), Turner & Zimmerman (1979), Vincent (1935a), Willis (1983), Zimmerman *et al.* (1996).

49. **Stripe-cheeked Greenbul**

Andropadus milanjensis

French: Bulbul montagnard **German**: Olivbrustbülbül **Spanish**: Bulbul de las Milanji
Other common names: Olive-headed Greenbul (*striifacies* and *olivaceiceps*)

Taxonomy. *Xenocichla milanjensis* Shelley, 1894, Mulanje, south Malawi.
Genus formerly submerged in *Pycnonotus*. Recent molecular studies have suggested possibility of close relationship between race *striifacies* and N races of *A. nigriceps* (nominate, *kikuyuensis*, *usambarae*), although the data are not statistically significant. Has also been proposed, on basis of morphological differences (including eye colour), that *olivaceiceps* and *striifacies* together be given status of a separate species; eye colour within both is variable, however, and vocal differences among races appear not to support such treatment; further studies needed. Poorly marked race



disjunctus (described from E Zimbabwe) considered indistinguishable from nominate. Three subspecies recognized.

Subspecies and Distribution.

A. m. striifacies (Reichenow & Neumann, 1895) – highlands of SE Kenya S to SW Tanzania (S to Udzungwas).

A. m. olivaceiceps (Shelley, 1896) – highlands of SW Tanzania (Rungwe), Malawi (except Mt Mulanje) and NW Mozambique (Unangu).

A. m. milanjensis (Shelley, 1894) – highlands of SE Malawi (Mt Mulanje), extreme E Zimbabwe and WC Mozambique.

Descriptive notes. c. 19 cm; male 33–45·5 g, female 34·5–47·5 g. A medium-large, brightly coloured greenbul with conspicuously marked ear-coverts, notable for racial variation in eye colour. Nominate race has grey head and neck, conspicuous white shaft streaking beneath eye and, particularly, on ear-coverts, conspicuous white crescent above eye, remainder of eyering narrower, paler and less contrasting; upperparts, including wings and tail, olive-green; chin and upper throat pale grey, lower throat and rest of underparts dull greenish-olive, darker on breast and flanks, yellower on belly; iris pale grey or brown; bill black; legs grey, greyish-brown or brown. Sexes alike, female on average smaller than male. Juvenile is as adult, but greener on crown, eye grey-brown. Race *striifacies* has top of head and neck bright olive-green, uniform with rest of upperparts (brighter than nominate), side of face contrastingly blackish, streaked white on cheeks and ear-coverts, no white eyebrow, chin olive-washed pale grey, underparts olive-yellow (brighter than nominate), eye pale bluish-grey, reddish-brown or, rarely, yellow (juvenile with dull-streaked greenish cheeks and ear-coverts, duller greyish-washed underparts, sepia bill with yellow gape, dark brown or sepia eye, light dusky grey legs); *olivaceiceps* resembles previous but is somewhat darker and greener above (though not as dull as nominate), greener, less yellow, below, with eye yellow in S of range but chestnut in N. Voice. Song 8–12 dry, short notes of same pitch, with distinct rhythm that varies regionally. In Zimbabwe (nominate race) song 4 measured notes followed by 3 delivered rapidly, ending with short trill, "chop-chap-chip-chip, chipa-chip, prrrr"; in N Malawi (*olivaceiceps*) slower, of up to 4–5 measured notes, "cho, cha, chip, cho, chip", "cherp, cho, cher, chip", "cherp, chorp, chip" or merely "were-chop"; in E Africa (*striifacies*) 3 measured notes and then 3 run together, ending with double note rather than trill, "chip-chop-chop, peechopee, chochop", also prolonged monotonous "piku-piku-piku-piku-piku…" and slower "qua quee-qua, qua quee-qua". Contact call is a loud rapidly repeated "cha", and (*striifacies*) "ookeri" or "u-ki-rii".

Habitat. Montane and submontane forest, riverine forest, adjacent scrub and thicket and, locally, plantations; found in both forest interior and edge habitats. Mainly 900–2145 m in E Africa and 1100–2000 m (rarely 2250 m) in Malawi, commonest at 1500–1800 m in Eastern Arc forests of Tanzania; descends to lower elevations during cold periods, moving down to 150 m in Usambaras, to 250 m in Ulugurus (Tanzania), to 600 m on Mt Mulanje (Malawi) and to 350 m at Haroni-Rusitu (Zimbabwe).

Food and Feeding. Omnivorous. Fruits, seeds; also arthropods, worms; also small vertebrates, including chameleons (*Chamaeleo*) and frogs (of genus *Arthroleptis*). Large range of fruits recorded (25 species in Malawi), e.g. *Loranthus*, *Lantana*, *Ficus*, *Rapanea* and *Sapium*; in Tanzania *Euclea*, *Teclea* and members of Rubiaceae recorded as eaten. Arthropods taken include beetles (Coleoptera), earwigs (Dermaptera), butterflies and caterpillars (Lepidoptera). Occurs both singly and in small vocal parties; many may gather at fruiting trees. Occasionally joins mixed-species flocks; sometimes attends *Dorylus* ant swarms. Forages mostly in middle and upper strata, but can be found at all levels. Gleans insects from branches and foliage, also in short aerial sallies. Sometimes shy and skulking, but can be more bold; attracted to fruiting bushes at or shortly beyond forest margin.

Breeding. Recorded in Oct, Dec–Feb, May and Jul in E Africa (birds in breeding condition and dependent juveniles in Jul–Aug, nest-building in Nov, in Tanzania); Sept–Oct in Malawi, Nov–Dec (in breeding condition in Aug) in Mozambique, and Oct–Mar (mainly Nov–Dec) in Zimbabwe. Monogamous; territorial. Nest a thin, neat rounded cup made of roots, grass, tendrils, twigs, bark fragments, and dead and skeletonized leaves, decorated externally with moss, lichens and cocoons, lined with fine grass, plant fibres and roots of tree-ferns, external diameter 9–13 cm, depth 6·5–8 cm, internal diameter 6·5 cm and cup depth 2–3 cm; built 2–7 m above ground, usually in vertical fork at top of well-foliaged subcanopy sapling, or in horizontal fork near end of branch, or well hidden between creeper stems. Clutch 2 eggs, sometimes 1; incubation by female only; no information on incubation and fledging periods.

Movements. Mainly resident; seasonal movements to lower altitudes during cold or dry seasons in at least some parts of range, as in Tanzania (Usambaras and Ulugurus) and Zimbabwe. One record from Pugu Hills (at 300 m), in coastal Tanzania, c. 200 km from nearest known breeding population.

Status and Conservation. Not globally threatened. Generally rather common. In Malawi, at least, densities vary considerably, highest in N, where at least 5 pairs/10 ha recorded; abundance much lower in areas where *A. nigriceps* is also present. In Tanzania, maximum density in Eastern Arc mountains c. 30 birds/km², while another study recorded 138 individuals/100 ha in Udzungwa Mts. Found in Arusha and Udzungwa National Parks, in Tanzania, Nyika National Park, in Malawi, and Chimanimani National Park, in Zimbabwe, as well as in numerous forest reserves across its range.

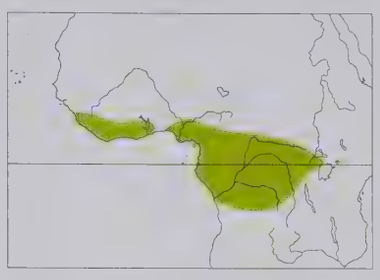
Bibliography. Benson & Benson (1977), Britton (1972, 1980), Brown & Britton (1980), Burgess & Mlingwa (2000), Chapin (1953), Clancey (1996), Cordeiro (1994a, 1994b), Cordeiro & Kiure (1995), Dowsett (1974), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire (1988, 1989), Dowsett-Lemaire & Dowsett (2004), Ginn *et al.* (1989), Hall & Moreau (1970), Harrison *et al.* (1997), Irwin (1981), Jensen & Brøgger-Jensen (1992), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louw (2005a), Mackworth-Praed & Grant (1960, 1963), Maclean (1993), Mlingwa (1996b), Moyer (1993), Romdal (2001), Roy *et al.* (1998), Sclater & Moreau (1932), Stevenson & Fanshawe (2002), Tarboton (2001), Turner & Zimmerman (1979), Vincent (1935a), Zimmerman *et al.* (1996).

50. Grey Greenbul

Andropadus gracilis

French: Bulbul gracile **German**: Zwergbülbül **Spanish**: Bulbul Grácil
Other common names: Little Grey Greenbul

Taxonomy. *Andropadus gracilis* Cabanis, 1880, Angola.



Genus formerly submerged in *Pycnonotus*. Sibling species of *A. ansorgei*. Similarities in appearance both to latter and to *A. curvirostris* have resulted in much confusion, historically and currently, which has obscured the status of each. Three subspecies recognized.

Subspecies and Distribution.

A. g. extremus Hartert, 1922 – W Guinea E to Togo and SW Nigeria.

A. g. gracilis Cabanis, 1880 – SE Nigeria (E of R Niger, also isolated population on Jos Plateau) E to C DRCongo and S to N Angola.

A. g. ugandae van Someren, 1915 – E DRCongo E to C Uganda and W Kenya.

Descriptive notes. c. 16 cm; male 18–23 g, female 19–28 g (*ugandae*). Small, short-tailed greenbul. Nominate race has top of head and neck olive-grey, lores and ear-coverts grey, slightly paler than crown, conspicuous contrasting white eyering; upperparts, including wings, olive-green, rump, uppertail-coverts and tail washed chestnut; throat and upper breast pale olive-grey, rest of underparts greyer with some yellowish-olive, undertail-coverts brown; iris brown, olive-brown or brownish-grey; bill black or dark brown; legs olive-green, brownish-horn or blue-grey. Distinguished from extremely similar *A. ansorgei* by yellow (not ginger) on underparts; from *A. curvirostris* by smaller size, more delicate bill, less contrasting throat, and much more visible eyering; from both of these also by voice. Sexes alike, female on average smaller than male. Juvenile is as adult, but brighter green above and yellow below, throat washed green, eyering yellowish, gape yellow, eye grey-brown, legs olive. Race *extremus* has breast and belly greenish-olive with yellow more extensive, almost pure yellow in centre of belly; *ugandae* is similar to previous, but yellow of underparts rather less bright. Voice. Song 4–5 rapid, jaunty notes, "wheet wu-wheet-wu-wheet", ascending at end, also quieter "tehu-tehee-tee", similar to that of *A. ansorgei* but with more syllables and more lively delivery. Call a short "tyuc tyuc".

Habitat. Primary and secondary evergreen and semi-deciduous forest, gallery forest, seasonal swamp-forest, and forest–savanna mosaic, with preference for edge habitats. Occupies many types of secondary habitat, including abandoned farmland, overgrown plantations, margins of logging roads, and similar; more common in secondary habitats than is *A. ansorgei*. Mostly lowlands, but to 1300 m in Cameroon, 1550 m in DRCongo and 1700 m in E Africa.

Food and Feeding. Fruits and seeds; also arthropods, including orthopterans, mantids, beetles (Coleoptera), moths and caterpillars (Lepidoptera), ants (Hymentoptera), spiders (Araneae); also small gastropods. Fruits taken include *Croton*, *Ficus*, *Macaranga*, *Musanga*, *Ochthocosmus*, *Rauwolfia*, *Trema*. Occurs singly, in pairs or in small family groups; occasionally joins mixed bird parties. Not shy. Forages at all heights, mainly in middle levels (8–15 m in Gabon, 10–25 m in Liberia), but also ranging on occasion up to canopy and down to bushes at 1–2 m in search of ripe fruit. Generally occurs lower down than *A. ansorgei* where the two sympatric. Also gleans from leaves, vegetation tangles, lianes, twigs, sometimes pursuing dislodged insects in short flights.

Breeding. Nesting recorded in May, birds in breeding condition in Nov–Dec and juvenile in Nov in Cameroon; in Jan and Aug, and in breeding condition in Nov–Dec (female soliciting copulation in Mar), in Gabon; elsewhere, birds in breeding condition Jun–Jul and Sept–Oct in Liberia, Jan and Jun in Ghana, Mar and Jul in Nigeria, Sept–Jun in DRCongo and Jan–Feb in Uganda; dependent juveniles seen in Jan in Ivory Coast. Monogamous; territorial. Nest an open cup of rootlets on base of dead leaves, bound together with thin, dry, twisted vines, smoothly lined with fine plant stems and fibres, green leaves incorporated in outer layer for camouflage, external diameter 10 cm, depth 7 cm, internal diameter 6·5 cm and cup depth 4 cm; built c. 2·5 m above ground in foliage at end of horizontal branch of isolated tree; one nest in early stages of construction, built by female alone, was a hammock of dead leaves bound together with cobwebs, base made of mycelium of *Marasmius* fungus, sited 8 m above ground inside bunch of leaves at junction of several twigs on horizontal branch in tree at edge of clearing. Clutch 2 eggs; incubation by female only; no information on incubation and fledging periods.

Movements. Little information; sedentary in Gabon.

Status and Conservation. Not globally threatened. Generally common, and widespread. Adaptable species. Estimated densities in Gabon 10–12 pairs/km² in old second growth and 5–6 pairs/km² in more disturbed habitat, such as farmland; estimated density in Nigeria 1 bird/3 ha. Occurs in numerous national parks, including those of Sapo, in Liberia, Taï Forest, in Ivory Coast, Kakum, in Ghana, Korup, in Cameroon, Lopé, in Gabon, Nouabalé-Ndoki, in PRCongo, Kahuzi-Biéga, in DRCongo, and Bwindi-Impenetrable Forest, in Uganda.

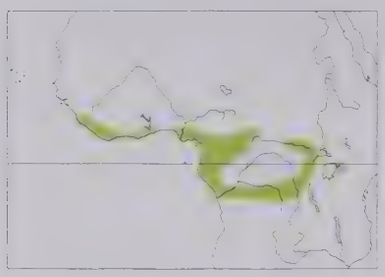
Bibliography. Bannerman (1936, 1953), Bennun (1994), Borrow & Demey (2001), Britton (1972, 1980), Brosset (1971a), Brosset & Érard (1986), Byaruhanga *et al.* (2001), Carswell (1986), Chapin (1953), Chappuis (1975), Cheke & Walsh (1996), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dean (2000), Demey & Fishpool (1994), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire (1996), Dowsett-Lemaire & Dowsett (1991), Elgood *et al.* (1994), Érard (1981), Fishpool & Evans (2001), Fishpool *et al.* (1994a), Gatter (1997), Grimes (1987), Hall & Moreau (1970), Jackson & Sclater (1938), Johnson, D.N. (1989), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1960, 1963, 1973), Mann (1985), Prigogine (1971, 1978, 1984), Rodewald *et al.* (1994), Sargeant (1993), Schouteden (1957), Stevenson & Fanshawe (2002), Thiollay (1985), Turner & Zimmerman (1979), Zimmerman (1972), Zimmerman *et al.* (1996).

51. Ansorge's Greenbul

Andropadus ansorgei

French: Bulbul d'Ansorge **German**: Ansorgebülbül **Spanish**: Bulbul de Ansorge

Taxonomy. *Andropadus ansorgei* Hartert, 1907, Degama, southern Nigeria.



Genus formerly submerged in *Pycnonotus*. Sibling species of *A. gracilis*. Similarities in appearance both to latter and to *A. curvirostris* have resulted in much confusion, historically and currently, which has obscured the status of each; consequently, distribution of nominate race uncertain in many areas. Two subspecies recognized.

Subspecies and Distribution.

A. a. ansorgei Hartert, 1907 – W Guinea E to Togo, SC Nigeria E to W Central African Republic and S PRCongo, NE, E & C DRCongo; also extreme SW Uganda.

A. a. kavirondensis (van Someren, 1920) – W Kenya.

Descriptive notes. c. 16 cm; male 19–21 g, female c. 20 g (nominate), male 17–19 g, female 17–23 g (*kavirondensis*). Small, short-tailed greenbul. Nominate race has top of head and neck olive-grey, lores and ear-coverts grey, slightly paler than crown, conspicuous white eyering; mantle, back and wings olive-green, rump, uppertail-coverts and tail reddish-brown; throat pale brownish-

grey, underparts olive-grey, becoming warm ginger on flanks and lower belly; undertail-coverts rufous-brown; iris dark brown, brown or chestnut; bill black to dark horn, paler cutting edges; legs dark olive or greyish-olive. Distinguished from very similar *A. gracilis* by lack of any visible yellow tones on underparts, from *A. curvirostris* by contrasting grey head, from both also by voice. Sexes alike, female on average smaller than male. Juvenile is as adult, but head and breast somewhat greyer, underparts below breast paler and buffy, gape yellow, legs pale olive. Race *kavirondensis* has grey of head tinged brown, olive-green upperparts also tinged brownish, slightly greyer breast and flanks, centre of belly with faint yellowish wash (visible only in the hand), undertail-coverts yellowish-brown. VOICE. Song "wheet-whuut-whit", "tiu-wheet-tweet" or "hweet tyu-hoo hweet", similar to that of *A. gracilis* but lacking its sprightliness; third syllable sometimes dropped. Also distinctive harsh, rapid, flat trill, "rititttitititit" or "tchitchitchithcithci", not given by *A. gracilis*.

Habitat. Primary and mature secondary evergreen and semi-deciduous forest. Common in dry inselberg forests in Liberia; absent from or very rare in similar habitat in Gabon. Less often in secondary habitats than is *A. gracilis*. Mainly lowlands; occasionally at middle altitude, e.g. 1400 m in Liberia and 1450 m in DRCongo.

Food and Feeding. Fruits, including *Allophylus*, *Macaranga* and *Musanga*, and seeds; also insects, including orthopterans, beetles (Coleoptera), moths and caterpillars (Lepidoptera). Usually seen in pairs, sometimes in small family parties; sometimes joins mixed-species flocks. Not shy. Often forages in crown of low trees, particularly in smaller branches. Mainly in upper middle stratum (25–45 m in Liberia), tending to occur at higher levels than *A. gracilis*, but does descend lower to attend small fruiting trees beside tracks, sometimes with latter species.

Breeding. Nesting recorded in May, birds in breeding condition in Jul and Oct and dependent fledgling seen in Jan in Liberia; in May, Jul and Oct–Dec in Nigeria; birds in breeding condition in Mar, Jul and Nov and juveniles in Nov in DRCongo, where species is suspected to breed through whole rainy season in NE (Ituri). One observation of a nest being built 30 m above ground. No other information available.

Movements. Little information; believed to be sedentary.

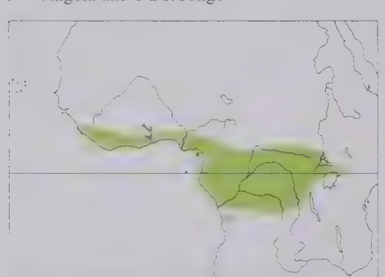
Status and Conservation. Not globally threatened. Status uncertain; considered uncommon to locally common, but situation unclear owing to continuing confusion with *A. gracilis*. Occurs in numerous national parks, including those of Sapo, in Liberia, Taï Forest, in Ivory Coast, Kakum, in Ghana, Korup, in Cameroon, Lopé, in Gabon, Nouabalé-Ndoki, in PRCongo, Salonga, in DRCongo, and Bwindi-Impenetrable Forest, in Uganda.

Bibliography. Bannerman (1936), Bennun (1994), Borrow & Demey (2001, 2002), Britton (1972, 1980), Brosset & Érard (1986), Chapin (1953), Chappuis (1975), Cheke & Walsh (1996), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Demey & Fishpool (1994), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1991), Elgood *et al.* (1994), Fishpool & Evans (2001), Fishpool *et al.* (1994a), Gatter (1997), Grimes (1987), Hall & Moreau (1970), Halleux (1994), Jackson & Sclater (1938), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1960, 1973), Prigogine (1971, 1978, 1984), Rainey & Lachenaud (2002), Rodewald *et al.* (1994), Sargeant (1993), Schouteden (1957), Stevenson & Fanshawe (2002), Thiollay (1985), Turner & Zimmerman (1979), Zimmerman (1972), Zimmerman *et al.* (1996).

52. Plain Greenbul

Andropadus curvirostris

French: Bulbul curvirostre **German**: Alexanderbülbül **Spanish**: Bulbul Piquicurvo
Other common names: Cameroon (Sombre) Greenbul



Taxonomy. *Andropadus curvirostris* Cassin, 1859, Camma River, Gabon.

Genus formerly submerged in *Pycnonotus*. May be most closely related to *A. gracilis* and *A. ansorgei*; similarities to both in appearance and behaviour have resulted in much confusion in the field, historically and currently, which has obscured its status. It has recently been suggested that vocal differences between the two races, and the fact that *leoninus* does not react to playback of song of nominate, may imply that they are isolated at the species level. Two subspecies currently recognized.

Subspecies and Distribution.

A. c. leoninus Bates, 1930 – Sierra Leone and SE Guinea E to C Ghana.

A. c. curvirostris Cassin, 1859 – C Ghana E, including Bioko I, to S Sudan and W Kenya, S to N & NW Angola and S DRCongo.

Descriptive notes. c. 17 cm; male 22–29 g, female 22–28 g. A medium-sized, almost featureless greenbul, difficult to identify by plumage characters alone. Nominate race has top of head dark olivaceous brown, side of face and ear-coverts olivaceous grey-brown, lores slightly darker, dirty white or grey broken eyering variable in width and degree of contrast; upperparts dark olivaceous brown, as crown, uppertail-coverts and tail reddish-brown; flight-feathers dark brown, edged olive-green; throat light olive-grey, contrasting somewhat with olive-brown breast; flanks olive-brown, belly yellow-olive, becoming pale yellow in centre of lower belly, undertail-coverts pale brownish-yellow; iris red-brown or chestnut-brown; bill black, paler cutting edges; legs olive, olive-green, dark green or dark greenish-grey. Distinguished from very similar *A. gracilis* and *A. ansorgei* by larger size, less conspicuous eyering, no obvious contrast between head and mantle, also by voice and habits; from *A. virens* by eyering, leg colour and voice. Sexes alike, female on average smaller than male. Juvenile is as adult, but belly more yellow, gape also yellow. Race *leoninus* is slightly darker above than nominate, less reddish on tail, greyer with less yellow below, no visible contrast between throat and breast. VOICE. Song of nominate race a 3-note "wheet-tiuwhee-tuu" or "wheet-tu-wheeu"; also has harsh trill, "trriiiii". Race *leoninus* has unobtrusive but distinctive "tiuwhee-tiu triiiii" or "su-hioo triiii", with stress on final, harsh upslurred trill, which also often given separately. Pitch lower than that of *A. gracilis* and *A. ansorgei*. Also a hard "wrrrrit" and a longer "wrrrrrititit".

Habitat. Primary and secondary evergreen and semi-deciduous forest, gallery forest, old regrowth, clearings and edge habitats. Mainly lowlands, locally at middle altitude, to 1800 m in DRCongo, 1600 m in Sudan and 2300 m in E Africa.

Food and Feeding. Fruits, seeds; also insects, and gastropods. Fruits taken include particularly *Rauwolfia*, also *Allophylus*, *Agelaea*, *Heisteria*, *Harungana*, *Musanga*, *Macaranga*, *Trema*, *Urera*. Insects especially caterpillars, also orthopterans, mantids, moths (Lepidoptera). Usually seen singly, in pairs or in small groups; frequently joins other bulbuls at fruiting trees or in mixed-species flocks. Unobtrusive and fairly shy, preferring to remain concealed in foliage; also perches silently for lengthy periods on low bare branches. Territorial, forages mainly in lower-middle levels, at tops of understorey shrubs and in lianes; mainly at 2–15 m (sometimes higher) in Gabon, 10–30 m in Liberia, 3–10 m in Kenya. Gleans insects from foliage, sometimes while hovering.

Breeding. Nesting recorded in Feb in Ghana and in Jan, Aug and Oct in Sudan; birds in breeding condition in May–Oct and independent young in Dec–Mar and Jun in Liberia; juveniles in Apr in Ivory Coast, and in Aug–Oct and Dec–Jan in Cameroon; increased vocal activity in Sept–Feb and females soliciting copulation Dec–Jan (short dry season) in Gabon; breeding condition in Sept–May in DRCongo, Feb–Mar (and immature in Feb) in Angola, and Jan–Feb, Apr and Jul in E Africa. Territorial. No other information.

Movements. Little information; thought to be sedentary in Gabon and Congo.

Status and Conservation. Not globally threatened. Status somewhat uncertain; considered not uncommon to common. Density in Gabon estimated tentatively at 10–12 pairs/km². Occurs in numerous national parks, including those of Sapo, in Liberia, Taï Forest, in Ivory Coast, Kakum, in Ghana, Korup, in Cameroon, Lopé, in Gabon, Nouabalé-Ndoki, in PRCongo, Salonga, in DRCongo, and Bwindi-Impenetrable Forest, in Uganda.

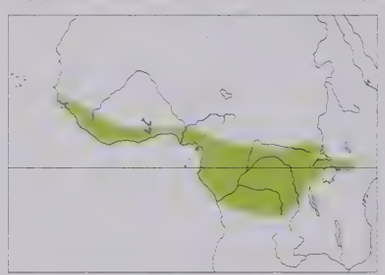
53. Slender-billed Greenbul

Andropadus gracilirostris

French: Bulbul à bec grêle **German**: Schmalschnabelbülbül **Spanish**: Bulbul Picofino



Taxonomy. *Andropadus gracilirostris* Strickland, 1844, island of Bioko (Fernando Póo), Equatorial Guinea.

Genus formerly submerged in *Pycnonotus*. Old name "*Stelgidillas poensis*" is a synonym of present species. Affinities unclear; recent molecular data suggest that this species is remote from all other members of genus and would be better placed in a separate genus. Proposed races *congensis* (Cameroon E to DRCongo and Tanzania) and *chagwensis* (Uganda) exhibit barely perceptible and inconstant differences in colour tone from nominate, and not satisfactorily distinguishable. Two subspecies recognized.

Subspecies and Distribution.

A. g. gracilirostris Strickland, 1844 – SW Senegal and Guinea-Bissau E, including Bioko I, to S Sudan, C Uganda and W Kenya, S to NW Angola, SC DRCongo, Rwanda and N Burundi, also W Tanzania.

A. g. percivali (Neumann, 1903) – C Kenya Highlands.

Descriptive notes. c. 18 cm; male 24–37 g, female 26–40 g. A medium-sized, two-toned, slender, relatively long-tailed greenbul. Nominate race has top of head olive-brown, lores and ear-coverts grey, the latter with some paler streaking, inconspicuous narrow grey eyering; upperparts, including uppertail-coverts and tail, olive-brown; flight-feathers dark olive-brown, edged greenish; pale brownish-grey below, paler than side of face, with throat, centre of belly and undertail-coverts even paler, greyish-white, breast and flanks sometimes washed olive; iris deep red, brick-red or red-brown; bill black; legs black or dark brown. Sexes alike, little difference in size. Juvenile resembles adult, but upperparts browner, breast and flanks washed brown, undertail-coverts cinnamon. Race *percivali* has upperparts more olive-green, less brown, than nominate, underparts paler, more whitish-grey, pale buff towards rear. VOICE. Clear, distinctive, downslurred, extended whistle, "tseeeeu" or "peeuuu", repeated frequently; also has more rarely used song of 4–5 whistled notes, "whee-ti-twheew-ti-whee" or "whuut-héét whuut-héét whuut-héét". Contact call a soft "frue" or "fu-wuwu"; alarm call an agitated "chewi" or "chew-chew".

Habitat. Primary and secondary evergreen and semi-deciduous forest, gallery forest, regenerating farmbush, large trees in farmland, patches of dense woodland in savanna, large gardens. Often in edge habitats, e.g. beside roads and in clearings. Lowlands, up to 1500 m in Liberia and Cameroon, to 2300 m in DRCongo, 2500 m in Rwanda and 2400 m in E Africa.

Food and Feeding. Fruits, including berries, and arils, also seeds; also arthropods, including orthopterans, mantids, bugs (Hemiptera), moths (Lepidoptera), caterpillars, ants (Hymenoptera) and spiders (Araneae). Fruits and arils include, in Gabon and PRCongo, those of *Allophylus*, *Croton*, *Ficus*, *Heisteria*, *Macaranga*, *Morinda*, *Musanga*, *Ochthocosmus*, *Rauwolfia*, *Xylocopia* and, in Rwanda, *Agalaea*, *Bridelia*, *Harungana*, *Ilex*, *Ocotea*, *Podocarpus*, *Syzygium*, *Polyscias*, *Rutidea*, *Sapium*, *Schleffera*, *Trema*, *Urera*. Usually occurs in pairs or small family groups, sometimes singly; large numbers may gather with other bulbuls in fruiting trees and lianes. Also joins mixed-species flocks, usually keeping to highest levels. Very much a species of tree canopies, usually above 25 m in lowland forest; infrequently comes lower, and then staying within crown of smaller trees and bushes. Forages through leaves and inflorescences for insects and fruit. Unobtrusive and quiet, rather than shy, but often calls while sitting upright in canopy. Estimated size of foraging territory in Gabon 8–12 ha.

Breeding. Nesting recorded in Jun and Sept–Jan in Sierra Leone, Oct and Dec in Liberia, Sept, Nov and Jan–Feb (juveniles early Sept) in Cameroon, Nov–Dec in Rwanda, Aug in Sudan; birds in

breeding condition in Feb in Ghana, Jun (young being fed in Jul) in Nigeria, in most months (suspected to breed all year) in DRCongo, Jun in Central African Republic, May and Nov in Uganda, and Jun (fledglings Nov) in Kenya; females soliciting food from males in Dec, Mar and Apr, also copulation observed in Apr, in Gabon. Territorial. Detailed observations only from one site in Sierra Leone. Nest constructed by one individual only, presumably female, accompanied by partner, latter sang at intervals and very occasionally carried nesting material, outer layer of nest built of dead or green leaves, lichens and cobwebs (but no moss), thin lining of petioles, placed in terminal fork of tree (*Dalium*, *Rauwolfia*, *Tecoma*) 6–7 m tall in partial shade, or isolated tree in garden, a little way from scrubby secondary forest. Elsewhere in Sierra Leone, nests often built at 15–20 m; in Gabon, female carrying dead leaves and plant fibres to canopy of tall forest tree, escorted by singing male; in Liberia, observations of nest construction at 7 m, 30 m and 38 m in trees. Clutch 2 eggs; incubation and provisioning, possibly also brooding, by both sexes; no information on incubation and fledging periods. Of four nesting attempts in Sierra Leone study, only one successful, with single young fledged; other three preyed on, possibly by vine snake (*Thelotornis kirtlandii*).

Movements. Little information; thought to be sedentary in Gabon.

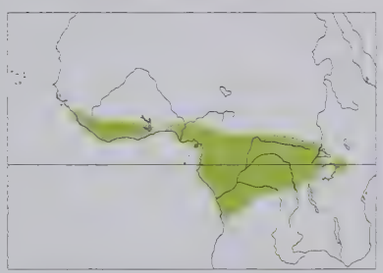
Status and Conservation. Not globally threatened. Generally common and widespread. Density in Gabon estimated at 7–9 pairs/km². Adapts well to secondary habitats. Well represented in protected areas.

Bibliography. Bannerman (1936, 1953), Barlow *et al.* (1997), Bennun (1994), Borrow & Demey (2001), Britton (1972, 1980), Brosset & Érard (1986), Brown & Britton (1980), Carswell (1986), Chapin (1953), Chappuis (1975), Cheke & Walsh (1996), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dean (2000), Demey & Fishpool (1994), Dowsett (1990), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire (1996), Dowsett-Lemaire & Dowsett (1991, 2001a), Elgood *et al.* (1994), Field (1993), Fishpool *et al.* (1994a), Gatter (1997), Grimes (1987), Hall & Moreau (1970), Halleux (1994), Heyman & Morlion (1980), Jackson & Sclater (1938), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1960, 1973), Mann (1985), Morel & Morel (1990), Nikolaus (1987, 1989), Pérez del Val (1996), Prigogine (1971, 1978, 1984), Rodewald *et al.* (1994), Rodwell (1996), Roy *et al.* (1998), Sargeant (1993), Schouteden (1957), Stevenson & Fanshawe (2002), Thiollay (1985), Turner & Zimmerman (1979), Waltert & Mühlenberg (1999), Zimmerman (1972), Zimmerman *et al.* (1996).

54. Yellow-whiskered Greenbul

Andropadus latirostris

French: Bulbul à moustaches jaunes **German**: Gelbbartbülbül **Spanish**: Bulbul Sibá



Taxonomy. *Andropadus latirostris* Strickland, 1844, island of Bioko (Fernando Póo), Equatorial Guinea.

Genus formerly submerged in *Pycnonotus*. Isolated population on Ufipa Plateau, in Tanzania, named as *australis*, is considered a synonym of nominate; conversely, has been proposed as a sibling species on basis of its paler underparts and, in particular, vocal differences. Other described races are *saturatus* (R Honi, in Kenya) and *eugenius* (W shore of L Victoria, in NW Tanzania), both poorly differentiated and also synonymized with nominate. Two subspecies recognized.

Subspecies and Distribution.

A. l. congener Reichenow, 1897 – SW Senegal and W Guinea E to SW Nigeria (W of R Niger).

A. l. latirostris Strickland, 1844 –SE Nigeria and Bioko I E to extreme S Sudan and C Kenya, S to N Angola, SC DRCongo and N Burundi, also N, NW & W Tanzania (Loliondo; Kigoma S to Kungwe-Mahare Mts; Ufipa Plateau).

Descriptive notes. c. 17 cm; male 25–35 g, female 23–32 g (nominate), male 24–31 g, female 12·5–25 g (*congener*). Medium-sized greenbul with distinctive yellow throat stripes. Nominate race has head and upperparts dark olive-green, bright yellow stripe on each side of throat; uppertail-coverts and tail dark reddish-brown, wings dark greenish-olive; centre of throat yellowish olive-green, underparts dull olive-green, flanks somewhat browner, centre of lower breast and belly pale yellow, undertail-coverts pale brown; iris dark brown, brown or grey-brown; bill black or dark brown, yellow cutting edges, tip and gape; legs distinctively orange-brown, yellow-brown or brownish-flesh. Sexes alike, female smaller (virtually no overlap in wing-length measurements of sexes in Kenyan Highlands). Juvenile resembles adult, but upperparts washed reddish, underparts dull brown, no malar stripes, basal half of lower mandible yellow, legs pinkish, bright orange or orange-yellow; malar stripes develop progressively, narrow at first, area of full extent intially dark. Race *congener* is slightly smaller than nominate, darker and greyer above, tail very dark, duller and greyer below, centre of belly whitish-yellow. Voice. Song a monotonous series of c. 12 "chruk" notes, slightly increasing in volume, repeated seemingly incessantly with pause of 5–30 seconds pause between each repetition; otherwise rendered "chuk, chik, chuk, chup, chik, tsup, chik-chik-chik tsuk, chik-chik-tsuck". Calls include repeated "chuk", rapid scolding "ditditditditdit" or "tip-tyip-tyip-tyip". Vocalizations of isolated Ufipa Plateau (Tanzania) population apparently highly distinctive, "zik, zik, zik, zik, zik, zik, zik" and monosyllabic "djeurr".

Habitat. Occupies both interior and edge of all types of primary and secondary forest, gallery forest, forest–savanna mosaic, thicket and large gardens; readily enters dense regrowth of abandoned cultivation, overgrown plantations, and regenerating logged forest. Sea-level to 1500 m in Liberia, to 1600 m on Bioko, 2200 m in Cameroon, 2300 m in DRCongo, 2700 m in Sudan, 3000 m in E Africa.

Food and Feeding. Fruit, including berries, and arils, also many arthropods; gastropods and small vertebrates (frogs, geckoes) also recorded as eaten. Fruit, berries and arils include those of *Agalaea*, *Allophylus*, *Bridelia*, *Capsicum*, *Cissus*, *Coelocaryon*, *Dacryodes*, *Ficus*, *Galiniera*, *Harungana*, *Heisteria*, *Ilex*, *Pycnanthus*, *Maesa*, *Morinda*, *Musanga*, *Ocotea*, *Sapium*, *Schleffera*, *Solanum*, *Trema*, *Tricalysia*, *Urera*, *Vitis*. Arthropods taken include orthopterans, mantids, flies (Diptera), beetles (Coleoptera), moths (Lepidoptera), caterpillars, ants (Hymenoptera), alate termites (Isoptera), spiders (Araneae), woodlice (Isopoda). Generally solitary, but will congregate with others, as well as with other pycnonotids, at fruiting trees; regularly attends *Dorylus* ant swarms, but otherwise rarely joins mixed-species parties. Usually shy and hard to see. Forages at all strata, but mainly at lower levels, below 5 m, ascending to lower canopy to visit crowns of fruiting trees. Prefers thin horizontal perches. Gleans insects from the ground, among fallen logs, etc., sometimes digging; frequently makes horizontal sallies to take insects from foliage, trunks and stems and lianes, and from the air. Hovers to pluck fruit. In intraspecific disputes, rivals raise the yellow malar stripes, make buzzy notes and chase each other.

Breeding. Nesting recorded in Oct–Mar (mainly Nov–Dec, in early dry season) in Liberia, May in Nigeria, May–Aug (and birds in breeding condition Feb–Oct) in Cameroon, Dec–Apr in Gabon, Jan, Mar and Sept–Nov in Rwanda, Jan–Feb and May–Jul in Sudan, Jan, Apr–May, Jul and Sept–Nov in Uganda, and Oct and Dec in Kenya; birds in breeding condition in Jun in Central African Republic, throughout year (peak in rains) in DRCongo, and Oct (immature seen in Feb) in Angola. System varies regionally: in some areas (usually where densities high) polygamous and non-territorial, uses leks and may be co-operative breeder; in parts of range where less abundant, e.g. Kenya, monogamous and territorial, remaining on territory in successive years, mean territory size 1·3 ha. In Gabon, males assemble during singing period (Sept–Apr) and sing in chorus at "traditional lekking sites" 100–200 m long, 40–50 m wide, often along roads or rivers, distance between leks 600–1200 m; male chooses songpost in dense undergrowth (from near ground level to canopy), space between singers may be only 10–20 m, males at centre of lek tend to large and heavy (perhaps dominant individuals); male defends area of c. 20 m in diameter, if intruder is female he displays towards her, with yellow moustaches prominent, rapidly beating wings drooped and somewhat curved, tail lowered and spread; females non-territorial, nests to within 2–3 m and in full view of each other, such nests often synchronized, several males may together defend a threatened nest. Nest constructed in 14 days (can be rebuilt in 5 days for second brood), a loosely built cup, outer layer of twigs, rootlets, strips of bark and plant fibres, inner layer of dry leaves, often bound together with cobwebs and hyphae of *Marasmius* fungus, lining of fine rootlets, dry grass or *Marasmius*, external diameter 9–12 cm, internal 5–8 cm, external depth 4–7 cm and cup depth 3–4 cm; placed 0·3–1·9 m above ground in dense undergrowth, often in fork of small bush or sapling and attached by means of vine tendrils. Clutch 1–4 eggs, usually 2; incubation by female only, period not documented; chicks fed by female alone in lek system, otherwise by both parents, nestling period 12–15 days; young largely independent on leaving nest, do not follow parents. Breeding success varies widely, with 45–85% (mean 75%) lost to predation annually; in Gabon, after two years in which no reproduction took place (possibly as anti-predator strategy), predation levels in third year (when breeding resumed) fell to 46% and population increased by 50%, but in succeeding four years nest predation rose to 78%.

Movements. Sedentary in some areas, nomadic in others. Mainly nomadic in areas where lek system used; in Gabon, 90% of population wanders and, of 791 individuals ringed, only 82 were retrapped. Recapture rates higher in other areas, e.g. Ogba Forest (Nigeria), where considered sedentary; sedentary individuals appear to have very small ranges, mostly recaptured where ringed. Reasons for sedentary behaviour by minority unclear; not thought related to age, sexual activity or physical condition. An altitudinal migrant on Mt Kupé, in Cameroon; absent above 1300 m in Apr–Sept, but occurs to 1950 m in dry season, though always less common above 1300 m.

Status and Conservation. Not globally threatened. Generally common to abundant throughout its wide range; often the most numerous bulbul, and sometimes the most abundant bird species, in many forests. Total population in Liberia thought to number at least 1,000,000 pairs. Density very variable, e.g. in Gabon estimated at up to 500 birds/km², in Nigeria at 1 bird/0·7 ha. Recently recorded for first time in Benin. Occurs in numerous national parks and other protected areas throughout its range, from Sapo National Park, in Liberia, E to Bwindi-Impenetrable Forest National Park, in Uganda, and S to Lopé National Park, in Gabon, and Kahuzi-Biéga National Park, in DRCongo.

Bibliography. van den Akker (2003), Bannerman (1936, 1953), Barlow *et al.* (1997), Bennun (1994), Borrow & Demey (2001), Bowden (2001), Britton (1972, 1980), Brosset (1971a, 1981a, 1981b, 1981c, 1982), Brosset & Érard (1986), Brown & Britton (1980), Carswell (1986), Chapin (1953), Chappuis (1975), Cheke & Walsh (1996), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dean (2000), Dowsett (1990), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1991), Elgood *et al.* (1994), Fishpool *et al.* (1994a), Gatter (1997), Grimes (1987), Hall & Moreau (1970), Heyman & Morlion (1980), Jackson & Sclater (1938), Johnson, D.N. 55. Little Greenbul

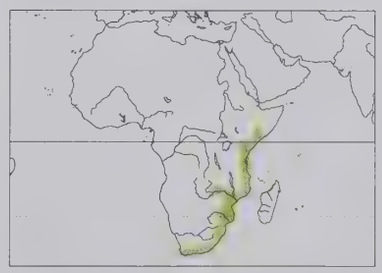
Andropadus virens

French: Bulbul verdâtre **German**: Grünbülbül **Spanish**: Bulbul Verde
Other common names: Little Green Bulbul; Hall's Greenbul ("*A. hallae*")

Taxonomy. *Andropadus virens*, Cassin, 1857, Cape Lopez and River Muni, West Africa.
Genus formerly submerged in *Pycnonotus*. Affinities unclear; may be closest to *A. latirostris*, to which it bears some resemblance in several aspects of behaviour. Described taxon *A. hallae*, known only from the single type specimen (from E DRCongo), now considered a melanistic form of present species. Race *amadoni* originally named as *poensis*, but that name preoccupied by "*Stelgidillas poensis*", a synonym of *A. gracilirostris*. Proposed race *holochlorus* (from R Sezibwa, in Uganda) is on average yellower below and slightly larger than nominate, but much individual variation and intergradation, and considered better merged with latter; similarly, *marwitzi* (Mt Kilimanjaro, in Tanzania) is poorly differentiated, merged with *zombensis*. Five subspecies currently recognized.
Subspecies and Distribution.
A. v. erythropterus Hartlaub, 1858 – Gambia E to E Nigeria.
A. v. amadoni Dickerman, 1997 – Bioko I.
A. v. virens Cassin, 1857 – W Cameroon E to extreme S Sudan and W Kenya, S to N Angola and S DRCongo.
A. v. zombensis Shelley, 1894 – SE DRCongo, N Zambia, N & SE Malawi, SE Kenya, Tanzania (Eastern Arc mountains, also Mafia I) and CN Mozambique.
A. v. zanzibaricus (Pakenham, 1935) – Zanzibar.



Descriptive notes. c. 16·5 cm; male 21–32 g, female 22–30 g. A small, uniformly plumaged greenbul, lacking any contrasts in plumage. Nominate race has head and upperparts, including wings, dark olive-green, uppertail-coverts and tail brown with brownish wash; eyering very indistinct or absent; throat pale olive-green, breast and flanks dark olive, centre of belly pale yellow, undertail-coverts pale brown; iris dark brown or grey-brown; bill black or dusky, yellow gape (sometimes lacking); legs yellowish-brown or yellowish-orange. Distinguished from *A. curvirostris* by lack of contrasting eyering, also by voice. Sexes alike, female on average smaller than male. Juvenile differs from adult in having wings browner, upperwing-coverts and secondaries with rusty wash, yellow of belly paler and less extensive, lower mandible, tip of upper mandible and gape yellow. Race *erythropterus* is greyer and darker above than nominate, with browner flight-feathers, less yellow on belly; *amadoni* is greener above and somewhat brighter yellow below than nominate; *zombensis* is more grey-green above and paler overall, including olive of underparts and yellow of belly; *zanzibaricus* is less green and darker above than previous, also greyer and less yellow below. Voice. Song, from well-concealed perch 2–3 m above ground, given relentlessly all day and for most of year, starts with a few subdued chuckling notes, succeeded by rapidly ascending series, forming pleasant bubbling warble, increasing in volume, ending on high, clear, rising note, "kwirk kwirk kwirk…chwukawuk-cherchickalee-chuck-chuk-chuk-tuwerrtlii-tuk-tuk-twee". Call a dry "kuk-kuk-kuk".
Habitat. Forest of all types, including primary and secondary evergreen and semi-deciduous forest, gallery forest, forest–savanna mosaic, swamp-forest, mangroves and riparian thicket, even gardens. Shows marked preference for secondary and edge habitats; in many places does not penetrate far inside high forest, and where it does may be in areas where *A. latirostris* less common (e.g. parts of Gabon). Sea-level to 1500 m in Liberia, to 2200 m in Cameroon, 1830 m in DRCongo, 1850 m in E Africa and 2050 m in Zambia.
Food and Feeding. Fruit, including berries, also many arthropods; may be largely frugivorous only seasonally. Fruits taken include those of *Allophylus*, *Asparagus*, *Cleistochlamys*, *Clidemia*, *Ficus*, *Lantana*, *Macaranga*, *Maesopsis*, *Musanga*, *Ochthocosmus*, *Polysphaeria*, *Rhus*, *Solanum*, *Sorindea*, *Tapinanthus*, *Trema*, *Xylotheca*. Arthropods taken include orthopterans, mantids, neuropterans, dipterans, beetles (Coleoptera), bugs (Hemiptera), ants (Hymenoptera), alate termites (Isoptera), spiders (Araneae). Found singly or in pairs; not gregarious, although several may gather at a fruiting tree, including with other bulbul species. Rarely joins mixed-species parties. Shy and skulking; forages mainly within thick cover, usually below 10 m, and down to ground level, particularly when attending *Dorylus* ant swarms. Will catch insects in flight over short distances, sometimes hovering briefly; also gleans from bark and leaves.
Breeding. Nesting recorded in Jun–Jul in Senegambia, Sept–Oct and Dec in Liberia, Feb and Apr–May in Ghana, Jan–Mar in Cameroon, Oct–Mar (especially Jan–Feb short dry season) and occasionally Jul–Aug (when short dry season late) in Gabon, Nov–Dec in PRCongo; in DRCongo, all year near equator and all months except Jun–Aug (short dry season) at Itombwe; Aug–Sept in Sudan, Jan–May and Sept–Oct in Uganda and W Kenya, Oct–Nov in Malawi, and May and Jul–Nov in Zambia; birds in breeding condition May–Jun and Sept in Nigeria, Mar–Sept (also juveniles Feb–Jul, breeding throughout year suspected) in Cameroon, Jan and Aug (juveniles in May) in Angola and Nov–May in coastal Tanzania. Territorial. Groups of 6–10 singing males recorded as collecting seasonally in small areas, may be related to breeding behaviour, but these areas (in contrast to leks of *A. latirostris*) differ from year to year; singing male beats wings, lowers tail and head, and puffs out feathers of throat and body; in probable pre-copulatory behaviour, presumed male sang from perch while presumed female flew silently between adjacent branches, and rapidly fluttered her wings while perched. Nest a shallow cup of dead leaves, twigs and bark fragments, sometimes bound with cobwebs and strips of bark, lined with plant fibres, fine rootlets and grasses and hyphae of *Marasmius* fungus, external diameter 10–11·5 cm, internal 6·5 cm, external depth 7 cm and cup depth 2–3·5 cm; placed low down, from just above ground to 1·5 m, in small shrub or fern tangle or under large leaves, suspended from twigs. Clutch 2 eggs, sometimes 3; incubation by female only, period at least 13 days; fledging period 11–12 days. In Gabon, 60% of nests preyed on.
Movements. Resident; some local wandering, e.g. of 114 birds ringed in Gabon only one retrapped (twice, after 8 and 23 months). Some evidence of altitudinal migration in Cameroon; during wet season on Mt Kupé, absent above 1400 m and scarce above 1100 m.
Status and Conservation. Not globally threatened. Extremely common across almost all of its extensive range. Total population in Liberia thought to be at least 4,000,000 pairs. Densities vary greatly; estimated 1 bird/2·5 ha in Nigeria, 2–6 pairs/10 ha locally in Malawi; in Tanzania, 444 individuals/100 ha in Udzungwa Mts, and in another study in Eastern Arc mountains reported maximum density c. 150 birds/km². Occurs in numerous national parks and other protected areas throughout its range, from Sapo National Park, in Liberia, E to Bwindi-Impenetrable Forest National Park, in Uganda, and S to Lopé National Park, in Gabon, and Kahuzi-Biéga National Park, in DRCongo. Given this species' preference for secondary habitats, its future seems assured.

56. Sombre Greenbul

Andropadus importunus

French: Bulbul importun **German**: Schlichtbülbül **Spanish**: Bulbul de Zanzibar
Other common names: Southern Sombre Greenbul (*importunus*); Zanzibar Sombre Greenbul (*insularis*); Frick's Sombre Greenbul ("*A. fricki*")

Taxonomy. *Turdus importunus* Vieillot, 1818, Outeniekwa Forest, Western Cape, South Africa.
Genus formerly submerged in *Pycnonotus*. Affinities of this species uncertain; no obvious close relatives, and generic placement by no means certain. Proposed taxon *A. fricki* (described from C Kenyan Highlands), resembling race *insularis* but with yellow eyering, now considered to be immature of that race. Size (weight) increases clinally from Kenya S to South Africa. Several proposed races too poorly differentiated to be safely distinguishable: thus, *somaliensis* (S Somalia) and *subalaris* (coastal Kenya) merged with *insularis*, *loquax* (SC Mozambique) with *hypoxanthus*, and *noomei* (NE South Africa) and *errolius* (E South Africa) with nominate. Four subspecies recognized.
Subspecies and Distribution.
A. i. insularis Hartlaub, 1861 – extreme S Ethiopia and S Somalia S to coastal C Tanzania (including Zanzibar).
A. i. hypoxanthus Sharpe, 1876 – coastal SE Tanzania (including Mafia I) S to Mozambique (N of R Save), and SC Zambia and Malawi S to Zimbabwe (except along R Limpopo).
A. i. oleaginus W. K. H. Peters, 1868 – S Zimbabwe (along R Limpopo), S Mozambique (S of R Save) and lowland N South Africa (S to N KwaZulu-Natal) and E Swaziland.
A. i. importunus (Vieillot, 1818) – highlands of N South Africa and W Swaziland S along coast to Western Cape.

Descriptive notes. 15–17·5 cm; male 25–30 g, female 22–27·5 g (*insularis*), male 26–40 g, female 24–33 g (other races). A medium-small, plain, pale-eyed greenbul. Nominate race has head and entire upperparts, including wings and tail, dark olive-green; throat and underparts uniform olive-grey, slightly paler on belly; iris white or pale yellow; bill black or slaty; legs black, slaty, grey or dark olive-brown. Sexes alike, female on average smaller than male. Juvenile is as adult, but brighter yellow below, olive-green wash across breast, richer olive-green above; bare-part development gradual, orange gape, brown iris and yellow eyering for first 3 months, by 6–9 months these all yellowish, at 9–12 months very faint yellowish gape, yellow iris and vestigial eyering, at 12–24 months as adult. Race *insularis* is slightly smaller than nominate, paler overall, with brownish-olive upperparts, tail somewhat darker, pale brownish-olive below, belly pale yellow, undertail-coverts pale yellow-brown; *oleaginus* has upperparts somewhat paler than nominate, throat, upper breast and flanks yellowish olive-grey, lower breast to undertail-coverts deeper, richer yellow; *hypoxanthus* resembles previous, but greener above, brighter yellow below. Voice. Loud and persistent vocalizations given throughout year, during breeding season virtually throughout day. Race *insularis* (Kenya) song includes short, rapid, slurred "chwelee-tuweeueet-tuweeuleet", rising at end, also "we-up-tchup-cheu-tew-wééa"; usual call note "cheeerurip" or "wheerúp" with emphasis on final syllable. In nominate race (South Africa), contact call a penetrating, rather ringing "willie"; song consists of "willie" call note followed by rapid jumble of equally loud notes, ending with either wheezing note or, more usually, downslurred whistle, transliterated as "willie, come and have a fight, sca-a-a-ared". Loud, excited "plee-plee-plee-plee" possibly an alarm call.
Habitat. Dense coastal scrub, thicket and forest, extending inland in riverine bush and forest; also occupies other types of bush, scrub and woodland, e.g. thickets in thornveld. In South Africa ascends mountain slopes along wooded valleys to reach evergreen forest in mist belt; in Mozambique in riparian reedbeds; in Kenya penetrates to 1220 m in the Chyulus and to 2000 m in S fringes of C Highlands; in Zambia to 1300 m, mainly below 600 m. Prefers natural vegetation, but occurs in various parts of its range in overgrown cultivation, woodlands of exotic trees, and gardens in well-wooded suburbs.
Food and Feeding. Mostly berries and other fruit, including *Bryoscarpus*, *Chassalia*, *Commiphora*, *Cyphostemma*, *Englerina*, *Ficus*, *Harrisonia*, *Hoslundia*, *Landolphia*, *Lantana*, *Ozoroa*, *Passiflora*, *Phyllanthus*, *Polysphaeria*, *Premna*, *Protea*, *Rhus*, *Securinega*, *Uvaria*. Arthropods and small gastropods also taken. Found singly or in pairs; sometimes larger flocks in non-breeding season. For-

Yellow-bellied Greenbul (*Chlorocichla flaviventris*); 64. Falkenstein's Greenbul (*Chlorocichla falkensteini*); 65. Simple Greenbul (*Chlorocichla simplex*); 66. Yellow-throated Greenbul (*Chlorocichla flavicollis*); 67. Swamp Palm Bulbul (*Thescelocichla leucopleura*).

ages by clambering through foliage in canopy, occasionally feeding in undergrowth or on the ground among leaf litter in low scrub. Shy and inconspicuous, keeping to dense cover, usually in canopy of forest or thicket, but inquisitive, emerges at intervals to sing from top of bush or exposed branch; dives quickly into cover when alarmed. Occasionally hawks aerial insects.
Breeding. Nesting recorded in Apr–Oct and Dec in Kenya, Jan, Mar, May and Oct (birds in breeding condition Nov–Dec and Feb) in Tanzania, in Zanzibar mainly Sept–Jan but also May–Jun; Aug–Feb and Apr in Malawi, Sept, Nov and Mar in Zambia, Sept–Apr (mainly Nov–Dec) in Zimbabwe and KwaZulu Natal; in South Africa, Jul–May in Eastern Cape and Sept–Apr in Western Cape, but mainly Oct–Nov in both provinces; at least some females double-brooded. Monogamous. Solitary nester, territorial. During pre-mating courtship display, partners faced each other on horizontal branch, male rapidly raising and lowering head in elliptical arc, periodically rotating slowly in complete turn while still head-bobbing, all the time with feathers of crown and nape raised, rapidly quivering slightly opened wings, and uttering soft keening call, female also bobbed head (out of phase with male), uttering same call. Nest built by female alone, usually a rather flimsy and thin-walled, shallow open cup made of fine stems of dry grass, twigs, rootlets, lichen and other plant fibres, lined with finer grasses, rootlets, other fine plant fibres, sometimes hair, external diameter 10–11 cm, depth 5–8 cm, internal diameter 5–6 cm and depth 3·7–4 cm; placed 1–4 m, usually 1·5–2·5 m, up and attached by cobwebs in fork of main stem of thickly foliaged slender tree or shrub, or at end of branch (then supported by foliage), often one somewhat isolated from others. Clutch 1–3 eggs, usually 2; incubation by female, male seen to bring food to her, period 12–17 days; chicks fed by both parents, at some nests brooded only by female, at others by both adults, nestling period 10·5–16 days; young fed for c. 3 weeks after leaving nest. Average of 1·73 chicks fledge per successful nest.
Movements. Sedentary; in S Africa, most ringed individuals have been recovered at original ringing sites for up to 10 years, with greatest movement 34 km. Flocks may wander locally in search of fruit during non-breeding season.
Status and Conservation. Not globally threatened. Generally common to abundant through much of its extensive range. Estimated densities of 21 birds/100 ha in acacia (*Acacia*) woodland in S Mozambique, where population for the region thought to exceed 100,000 individuals; densities in Swaziland estimated at 2 birds/100 ha in acacia savanna, 38 birds/100 ha in broadleaf woodland and 92 birds/100 ha in riverine forest. Adaptable; able to thrive in variety of habitats, including secondary ones. Well represented in protected areas.

Genus *CALYPTOCICHLA* Oberholser, 1905

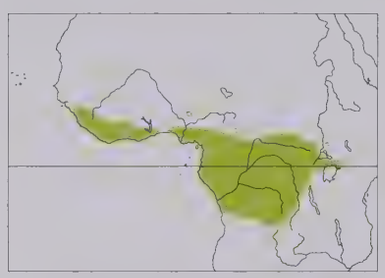
57. **Golden Greenbul**

Calyptocichla serina

French: Bulbul doré **German**: Goldbülbül **Spanish**: Bulbul Dorado
Other common names: Serine Greenbul

Taxonomy. *Criniger serinus* J. Verreaux and E. Verreaux, 1855, Gabon.
Distinctive species, with no obvious close relatives. Monotypic.
Distribution. Sierra Leone and SE Guinea E to Togo, and SW Nigeria E to SW Central African Republic and S, including Bioko I, to W PRCongo and N Angola (Cabinda), also extreme W and parts of NC, NE & E DRCongo.

Descriptive notes. c. 18 cm; male 36·4–42 g, female 35–42·5 g. A medium-sized greenbul with distinctive golden coloration and pale bill. Plumage is wholly yellowish olive-green above, including tail and wings, brightest on rump; lores and ear-coverts yellowish-olive, some indistinct paler streaking on ear-coverts; chin and upper throat whitish, lower throat yellow, breast and flanks yellowish-green with some paler yellow shaft streaking, lower breast, belly and undertail-coverts bright golden-yellow; iris dark grey, brown or pale grey-brown; bill pale pinkish or light brown, tip darker, base of lower mandible whitish; legs grey, olive-grey, dark blue, greenish-blue or dull dark red. Sexes alike, female on average smaller than male. Juvenile resembles adult but duller below, throat pale yellow. Voice. Song, given only during nesting period, a short, clear "tiup-chiweew", stress on last syllable; many variations, some introducing third note, "wep-chep, wep-chep", "whit-tu-tiup", "tiu-tu-tip", "tchu tchi-tyu" and similar. Calls include short "tsip" or "tyip" and, in flight, thin, high-pitched "see".
Habitat. Evergreen and semi-deciduous forest, both primary and secondary, isolated forest patches; often in edge habitats. Enters cacao plantations and forest in later stages of regeneration on abandoned farmland; favours young secondary *Sarcophyrnium* forest and secondary growth of Burseraceae and Myristicaceae in Gabon. Sea-level to 1200 m in Liberia, to 1300 m in Cameroon.
Food and Feeding. Fruit, including *Ficus*, *Heisteria*, *Macaranga*, *Morinda*, *Ochthocosmus*, *Rauwolfia*, *Xylopia*, and small seeds. Also insects, including orthopterans, alate termites (Isoptera) and caterpillars. Occurs singly, in pairs or in small family parties; sometimes joins mixed-species flocks. Forages largely in emergent trees, in canopy and subcanopy, usually above 20 m, occasionally coming lower to fruiting bushes; often calls from canopy while sitting erect. Often seen in fruiting trees with *A. gracilirostris*. Gleans insects from leaves; makes aerial sallies after alate termites.
Breeding. Nesting recorded in Mar and Apr in Cameroon, Dec–Feb (and birds in Breeding condition in Sept) in Gabon, and Jan and Nov in DRCongo; in breeding condition in Aug in Nigeria; fledgling being fed by adults in Mar in Liberia, and begging juveniles in Mar and immature in May in Ivory Coast. Territorial; displays of aggressive behaviour during nesting season. Nest built by female, attended by singing male, made of dry leaves and plant fibres, placed in fork surrounded by leaves at end of horizontal branch 30–40 m above ground in tree crown. Clutch size unrecorded; incubation by female only, young fed by both parents.
Movements. Highly mobile, thought to be nomadic over large areas.
Status and Conservation. Not globally threatened. Widespread, but nowhere particularly common. Density in Gabon estimated at 10–12 individuals/km². Occurs in numerous national parks, including those of Sapo, in Liberia, Taï Forest, in Ivory Coast, Kakum, in Ghana, Cross River, in Nigeria, Korup, in Cameroon, Lopé, in Gabon, Nouabalé-Ndoki, in PRCongo, and Salonga, in DRCongo.
Bibliography. Bannerman (1936, 1953), Borrow & Demey (2001), Britton (1972), Brosset (1971a), Brosset & Érard (1986), Chapin (1953), Chappuis (1975), Chappuis & Érard (1993), Cheke & Walsh (1996), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dean (2000), Demey & Fishpool (1994), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire (1996), Dowsett-Lemaire & Dowsett (1991), Elgood *et al.* (1994), Fishpool & Evans (2001), Fishpool *et al.* (1994b), Gatter (1997), Grimes (1987), Hall & Moreau (1970), Halleux (1994), Keith *et al.* (1992), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1960, 1973), Pérez del Val (1996), Prigogine (1971, 1978, 1984), Rainey & Lachenaud (2002), Rodewald *et al.* (1994), Sargeant (1993), Schouteden (1957), Thiollay (1985).



Genus *BAEOPOGON* Heine, 1860

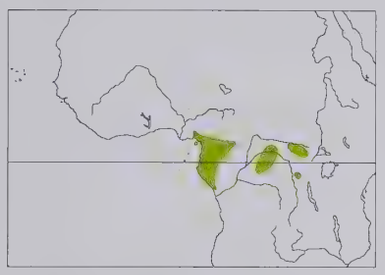
58. **Honeyguide Greenbul**

Baeopogon indicator

French: Bulbul à queue blanche **German**: Weißchwanzbülbül **Spanish**: Bulbul Indicador

Taxonomy. *Criniger indicator* J. Verreaux and E. Verreaux, 1855, Gabon.
Proposed race *togoensis* (E Ghana and Togo) considered not satisfactorily distinguishable from *leucurus*. Two subspecies recognized.
Subspecies and Distribution.
B. i. leucurus (Cassin, 1855) – W Guinea E to Togo.
B. i. indicator (J. Verreaux & E. Verreaux, 1855) – SW & C Nigeria (including isolated population on Jos Plateau) E to extreme S Sudan and W Kenya, S to N Angola, S DRCongo and extreme NW Zambia.

Descriptive notes. c. 19 cm; male 44–53 g, female 40–48 g. A stocky, medium-sized greenbul with pale eyes, mostly white outer tail feathers (flashed conspicuously in flight, possibly as intraspecific recognition signal). Male nominate race has lores, cheeks and ear-coverts uniform grey, washed olive; top of head and upperparts, including wings, greenish-olive, slightly darker on crown and greyer on nape; central two pairs of tail feathers blackish, third pair (T3) blackish on inner web and on terminal 2 cm or so of outer web, remainder of outer web white, outer rectrices (T4–T6) white with creamy edges and dark tips, latter becoming progressively narrower outwards (down to c. 7 mm on outermost); throat grey, breast and flanks dark olive-grey, lower breast, centre of belly and undertail-coverts creamy buff; iris white, creamy or greyish-white; bill black or dark grey; legs grey or slate. Differs from *B. clamans* in having grey (not buffy) breast, throat concolorous with breast, white outer tail feathers tipped dark, pale eye. Female is on average smaller than male, differs also in having eyes brown to grey. Juvenile resembles adult, but duller above, belly grey-white, outer three pairs of tail feathers wholly white, dark tip of T3 much less extensive, eyes of young male dull greyish-buff. Race *leucurus* is greyer, less olive, below than nominate, belly and undertail-coverts brighter, creamy white, and (contrary to published statements) both sexes have eyes creamy white. Voice. Distinctive; main song a clear, vigorous turdid-like whistle comprising a series of 8–10 melodious notes, the last extended and descending, "keerriup keeup kuileep turee tzeeeeew", often abbreviated to rapid "vik-vik-viiieew" or "tiu-liuuw". Also single mewing note, "teeueeep" or "squeeeeueee".
Habitat. Evergreen and semi-deciduous forest, both primary and secondary, gallery forest; fond of edges and clearings, treefall gaps, second growth with *Musanga* along logging roads, isolated forest patches, and strips left beside swampy areas in cultivation, cacao plantations, etc. Mainly lowlands, but recorded to 1000 m in Liberia, 1700 m in DRCongo, 1460 m in Zambia and 2000 m in E Africa.
Food and Feeding. Berries and other fruit, including *Ficus*, *Croton*, *Heisteria*, *Macaranga*, *Musanga*, *Rauwolfia*, *Trema*, *Xylopia*. Also arthropods, including beetles (Coleoptera), caterpillars, ants (Hymenoptera), alate termites (Isoptera) and spiders (Araneae). Found singly, in pairs, or in small family groups of up to seven individuals; sometimes joins mixed-species flocks. Forages mainly in upper strata, from 10 m to canopy, occasionally lured down to 5 m by fruiting bushes, and sometimes to isolated trees and bushes some way from forest edge. Restless, active and often vocal for much of day. Seeks insects in tree canopies, leafy tangles, lianes and similar, sometimes gleaning them from leaves by hovering. Infrequently attends doryline ant swarms, then catching prey on the wing or snatching items from stems and trunks.
Breeding. Nesting observed in Jun (but thought to breed most of year) in DRCongo and Nov in Gabon; nest-building recorded in Mar in E Africa; birds in breeding condition in Feb in Sierra Leone, Nov–Dec and Feb (and independent juvenile in Mar) in Liberia, Feb (and nest-building in Aug) in Ghana, Sept–Mar in Nigeria, and Dec in Central African Republic; in breeding condition Aug–Nov in Zambia. Territorial, in Gabon defending area estimated at 15–18 ha with displays and vocalizations; territory in Kenya at least 4 ha. Male seen to feed female with berries. Only one nest described, a loosely built cup of dead leaves and twigs, lined with thin yellow plant stems (contrasting with drab colour of exterior), external diameter 7·5 cm, depth 5 cm, internal diameter 5·5 cm and cup depth 4 cm, placed c. 8 m above ground and secured to two small twigs of branch of orange tree near road (and c. 20 m from a building). Clutch presumed 2 eggs, as two chicks recorded in the nest; incubation by female only. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Fairly common and widespread across its range. Estimated densities 4–10 pairs/km² in Liberia and 6–8 pairs/km² in Gabon, and 1 bird/10 ha in Nigeria. Recorded in numerous national parks, including those of Sapo, in Liberia, Taï Forest, in



Ivory Coast, Kakum, in Ghana, Korup, in Cameroon, Lopé, in Gabon, Nouabalé-Ndoki, in PRCongo, Salonga, in DRCongo, and Kibale Forest, in Uganda.
Bibliography. Bannerman (1936, 1953), Bennun (1994), Benson *et al.* (1971), Borrow & Demey (2001), Britton (1972, 1980), Brosset (1971a), Brosset & Érard (1986), Brown & Britton (1980), Carswell (1986), Cave & MacDonald (1955), Chapin (1953), Chappuis (1975), Chappuis & Érard (1993), Cheke & Walsh (1996), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dean (2000), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett *et al.* (2004), Dowsett-Lemaire (1996), Dowsett-Lemaire & Dowsett (1991), Elgood *et al.* (1994), Fishpool & Evans (2001), Fishpool *et al.* (1994b), Gatter (1997), Germain & Cornet (1994), Grimes (1987), Hall & Moreau (1970), Herroelen (1955), Jackson & Sclater (1938), Johnson, D.N. (1989), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1960, 1963, 1973), Nikolaus (1987, 1989), Prigogine (1971, 1978, 1984), Rodewald *et al.* (1994), Sargeant (1993), Schouteden (1957), Stevenson & Fanshawe (2002), Thiollay (1985), Turner & Zimmerman (1979), Zimmerman (1972), Zimmerman *et al.* (1996).

59. Sjöstedt's Greenbul

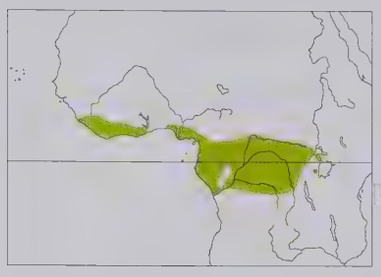
Baeopogon clamans

French: Bulbul bruyant **German**: Sjöstedtbülbül **Spanish**: Bulbul Chillón
Other common names: White-tailed Greenbul, Sjöstedt's Honeyguide Greenbul

Taxonomy. *Xenocichla clamans* Sjöstedt, 1893, Ekundu, Cameroon.
Monotypic.
Distribution. Extreme SE Nigeria S to S PRCongo and E, apparently patchily, to E DRCongo.

Descriptive notes. c. 19 cm. Medium-sized greenbul with conspicuous white outer tail feathers. Forehead is grey-olive, crown to neck olive-green with narrow darker fringed (scaly appearance); lores and ear-coverts grey; upperparts, including wings, bright yellowish-green; central two pairs of tail feathers blackish-brown, third pair (T3) dark on inner web, outer web white except for dark final centimetre or so, three outer pairs wholly white, outer webs broadly edged yellow; chin and upper throat grey, lower throat and side of neck buff (this colour sometimes extending up side of upper throat); breast and upper belly greyish-buff, washed yellowish, flanks grey-olive, lower belly and undertail-coverts rich buff; iris dark reddish-brown or dull red; bill black or dark grey, paler cutting edges and tip; legs grey or blue-grey. Differs from *B. indicator* in having throat colour contrasting with breast, buffy (not grey) breast, no dark tips on white outer tail feathers, eyes dark. Sexes alike, female on average smaller than male. Juvenile is duller than adult, with buffy areas paler. Voice. Emphatic, far-carrying, harsh, nasal "whéw" or "chyaa", or "pyow", much repeated (up to 15 minutes on end) and often running into rapid nasal babble, "teeturuteetutwhee".
Habitat. Primary forest and old secondary forest, particularly near water, along riverbanks and beside small forest streams; mainly in lowlands, reaching 1500 m in DRCongo. Prefers forest interior rather than edge habitats, in contrast to *B. indicator*.
Food and Feeding. Berries and other fruit, including *Heisteria* and *Musanga*. Also insects, such as moths and caterpillars (Lepidoptera), but particularly the immature stages of the small black wasp *Polybioides melaina* and other hymenopterans; young fed exclusively with larvae, pupae and wax from nests of these. Found singly, in pairs or in small groups; sometimes joins mixed-species flocks. Forages from middle level to subcanopy, occasionally lower, gleaning insects from leaves and searching for fruit. Tears apart nests of hymenopterans in order to reach contents.
Breeding. Nesting recorded in Nov–Dec in Cameroon; in Feb (and carrying nest material in Jan) in Gabon, where breeding season suspected as spanning two rainy seasons and intervening dry season; birds in breeding condition in Feb–Mar and Jul in DRCongo. Territorial all year; territory 8–10 ha, defended with song and aggressive displays. Spreads tail to display white outer feathers when calling. Nest a loosely built cup of dead leaves bound together with rootlets and vine stems, suspended hammock-like between small branches and attached by cobwebs, with camouflaging leaves and twigs hanging from underside, attached by hyphae of *Marasmius* fungus; one built 15 m above ground in leaves at end of branch of 25-m tree beside river in small clearing, another at 10 m in a 20-m understorey tree. Clutch size not documented; two young, fully feathered at 15–16 days, fed by female, male watched from nearby and started singing as she approached with food, he approached nest while still singing (female sometimes answered) and waited a few metres from nest while female fed young.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Locally fairly common. Estimated density in Gabon 6–8 pairs/km², similar to that of *B. indicator*. Distribution partially related to that of the wasp *Polybioides melaina*; often found in vicinity of this hymenopteran's large paper nests, which often built close to watercourses. Occurs in a number of national parks, including those of Cross River, in Nigeria, Korup, in Cameroon, Dzanga-Ndoki, in Central African Republic, Lopé, in Gabon, Odzala, in PRCongo, and Salonga, in DRCongo.
Bibliography. Bannerman (1936, 1953), Borrow & Demey (2001), Brosset & Érard (1986), Chapin (1953), Chappuis (1975), Christy & Clarke (1994), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1991), Elgood *et al.* (1994), Érard (1977), Fishpool & Evans (2001), Hall & Moreau (1970), Keith *et al.* (1992), Lippens & Wille (1976), Louette (1981, 1984), Mackworth-Praed & Grant (1973), Prigogine (1971, 1978, 1984), Rodewald *et al.* (1994), Sargeant (1993), Schouteden (1957).

Genus *IXONOTUS*



J. Verreaux & E. Verreaux, 1851

60. Spotted Greenbul

Ixonotus guttatus

French: Bulbul tacheté **German**: Fleckenbülbül **Spanish**: Bulbul Moteado

Taxonomy. *Ixonotus guttatus* J. Verreaux and E. Verreaux, 1851, Gabon.
Proposed race *bugoma* (upper DRCongo E to Bugoma Forest, in Uganda), with forehead on average browner, less grey, is considered not satisfactorily distinguishable. Monotypic.
Distribution. Sierra Leone and SE Guinea E to Ghana, and SW Nigeria E to WC & S Uganda and extreme NW Tanzania, S to S PRCongo, N Angola (Cabinda) and SC DRCongo (S as far as Kwango, Kasai, Maniema and Kivu).

Descriptive notes. c 17 cm; male 31–40 g, female 34–38 g. Small greenbul, distinctive in plumage and behaviour. Lores are whitish, periorbital area and ear-coverts grey-brown with some ill-defined paler streaking; top of head and neck greyish-olive with dark feather tips (appearing scaly), mantle and upper back olive; lower back, rump, uppertail-coverts, scapulars, upperwing-coverts and tertials dark olive-brown with large white or yellowish spots at tips; flight-feathers brownish-olive; central two pairs of tail feathers blackish, third pair (T3) with outer web white, inner web blackish, three outer pairs wholly white; chin and throat white, separated from lores by narrow blackish line extending back from gape; underparts, including underwing-coverts, creamy white, tinged yellow, particularly on lower belly and flanks; eye of male brown, red-brown, grey-brown or creamy; upper mandible dark grey, lower mandible grey, pinkish-grey or grey-brown; legs greyish, variable. Female is on average smaller than male, differs also in having eyes pale brown, greyish-white or pale yellow. Juvenile resembles adult. Voice. Distinctive dry chirping or "ticking" call, resembling noise made by electric spark, repeated incessantly; also has double note, "tsi-tsirit", sometimes 3–4 notes together, sometimes single "tsit".
Habitat. Evergreen and semi-deciduous forest, both primary and, less commonly, secondary, also gallery forest, forest–savanna mosaic and cacao plantations. Found both in forest interior and in edge situations, around clearings, etc. Mainly lowlands, but to 1250 m in Uganda and to 1300 in DRCongo.
Food and Feeding. Fruit, particularly figs (*Ficus*), also *Heisteria*, *Macaranga*, *Musanga*, *Ochthocosmus*, *Rauwolfia*; also insects, including caterpillars, alate termites (Isoptera) and ants (Hymenoptera), collected from bark. Nestlings fed with fruit and caterpillars. Most gregarious African bulbul, occurs in monospecific groups of 5–50 (usually 7–15) individuals throughout year. Groups restless, constantly on move, never spending long in one tree, continuously making contact calls; sometimes briefly join other species at fruiting trees, but very rarely with mixed-species flocks. Forages mainly between 10 m and canopy, sometimes lower. Gleans insects energetically from leaves and, especially, from underside of horizontal branches 1–10 cm in diameter; works over branches methodically, peering over one side, then bounding forwards to peer over other side a little way ahead, twisting through c. 70 degrees each time. Will also hover to take prey from beneath a branch. Has distinctive habit, particularly while foraging, of rapidly raising and lowering first one wing and then the other, lifting it towards vertical, bent at "elbow" (white underwing-coverts conspicuous); also flicks tail and fluffs out rump feathers. Several foraging individuals may come together briefly, pausing in groups of up to five, sitting closely side by side, pressed together, each peering around, stretching, flicking tail and one wing, before moving off independently, only to reassemble with same or other individuals farther on.
Breeding. Nesting recorded in Mar–May, Jun and Aug (young in Oct) in Cameroon, and in Dec–Feb, Apr, Jun–Jul and Oct (probably all year) in DRCongo; birds in breeding condition in Aug and dependent young in Sept in Liberia; nest-building in Nov and begging juveniles in Jul–Aug and Oct–Nov in Ivory Coast, and nest-building in Jun–Sept in Nigeria; flying young in Feb and Oct in Gabon. Co-operative breeder, nestling and fledglings fed by group of 4–6 birds. Nest an open, shallow, rounded or oval cup, somewhat frail and crudely constructed from dry leaves, petioles, rootlets and bark fragments, bound together with cobwebs, lined with thin layer of rootlets, external walls decorated with tiny pellets of regurgitated seeds (perhaps for camouflage or strengthening); diameter of round nests 7–7·5 cm externally, 6–6·5 cm internally, oval nests 7·5 × 8·5 cm externally, 6 × 7 cm internally, external depth 2·5–6 cm, cup depth 2–2·5 cm; placed 2·5–8 m above ground in fork of small tree or bush (wild or cultivated), sometimes near a road, once within knot-hole on upper surface of horizontal branch 10 m high in kola nut tree in farmland choked with second growth. Clutch 2 eggs; no information on incubation and nestling periods.
Movements. Uncertain; thought to be sedentary for part of year, nomadic at other times. Largest groups in Gabon in long dry season, when fruiting trees more scattered; groups roam over areas of at least several dozen ha.
Status and Conservation. Not globally threatened. Locally common to scarce across its wide range. Estimated density 1 bird/2 ha in Nigeria. Occurs in numerous national parks, including those of those of Sapo, in Liberia, Taï Forest, in Ivory Coast, Kakum, in Ghana, Cross River, in Nigeria, Korup, in Cameroon, Lopé, in Gabon, Nouabalé-Ndoki, in PRCongo, and Salonga, in DRCongo; also in Budongo Forest, in Uganda.

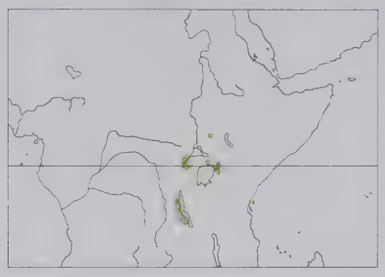
Genus *CHLOROCICHLA* Sharpe, 1882



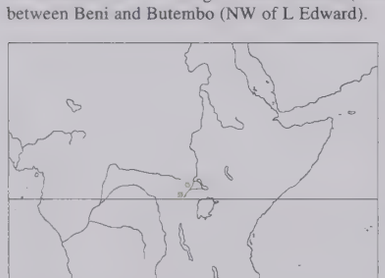
61. Joyful Greenbul

Chlorocichla laetissima

French: Bulbul joyeux **German**: Dotterbülbül **Spanish**: Bulbul Alegre

Taxonomy. *Andropadus laetissimus* Sharpe, 1899, Nandi, Kenya.
May form a species pair with *C. prigoginei*. Two subspecies recognized.

Subspecies and Distribution.
C. l. laetissima (Sharpe, 1899) – extreme S Sudan (Imatong Mts), NE DRCongo (Lendu Plateau S to highlands W of L Edward), W Uganda and SW Kenya.
C. l. schoutedeni Prigogine, 1954 – E DRCongo (Mt Kabobo, Marungu Highlands) and extreme N Zambia (Kasangu).

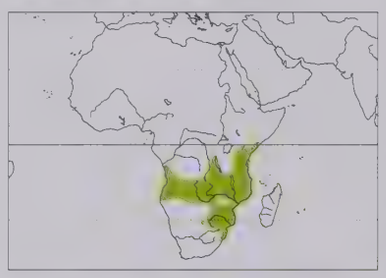


Descriptive notes. 20–21 cm; male 47–54 g, female 43–55 g. A large, distinctive golden-olive greenbul. Nominate race has lores and short stiff feathering around base of upper mandible brownish-yellow, indistinct yellow supercilium and yellow upper eyelid, yellowish-olive cheeks and ear-coverts, rest of head and whole of upperparts bright yellowish-olive, crown feathers dark-centred (appearing scaly at close range); wings feathers dark brown with yellowish olive-green outer webs; tail olive-green, edged yellowish; chin and throat bright yellow, breast and flanks yellow, tinged greenish, belly and undertail-coverts bright yellow; iris bright chestnut, reddish-brown or brown; bill black, cutting edges and tip brown; legs black, blue-grey, greenish-grey or grey-brown. Differs from *C. prigoginei* in larger size, yellow (not white) chin, yellow (not grey) lores and preocular area, absence of contrasting pale eyering. Sexes alike, female on average smaller than male. Juvenile is browner above, greener below. Race *schoutedeni* is darker above than nominate, particularly on neck and side of head, also darker, more olive, on breast and flanks. Voice. Song a boisterous, cheerful, bubbling chatter lasting 4–5 seconds, "chuck-chuck-chweek-kweek-kuardl-chuker-erk-querk"; during courtship, "chukliskéékseu, chwukiliskéékskew" repeatedly. Call a sharp "chik" or "chak".
Habitat. Mid-altitude and montane evergreen primary and secondary forest, gallery forest and isolated forest patches, at 1050–2300 m. Favours more open areas, clearings and edge habitats.
Food and Feeding. Berries and seeds. Nestling of captive pair fed with fruit and "live food", including moth (Lepidoptera). Occurs in monospecific flocks of 4–12 individuals; occasionally joins mixed-species flocks. Forages mainly within lower and middle strata, sometimes in canopy, rarely in undergrowth. Groups vocal and conspicuous; flicks wings while foraging. Two records of flocks accompanied by single *C. prigoginei*.
Breeding. Nesting recorded in Mar in Sudan and Jul in Kenya. Displaying bird pumps tail, droops wings and puffs out throat feathers when singing. No other information from wild. Following details from one pair in captivity: nest an open cup of Spanish moss, rootlets and fine grasses, external depth 6·5 cm; chick almost fully feathered 7 days after hatching, fed by both parents, fully independent by 31 days (but already feeding itself by then).
Movements. No information; probably sedentary.
Status and Conservation. Not globally threatened. Uncommon to locally common; distribution patchy, absent from many seemingly suitable areas. Known from a number of protected areas, including Imatong Mountains Forest Reserve, in Sudan, Okapi Faunal Reserve and Virunga National Park, in DRCongo, Kibale Forest and Mount Elgon National Parks, in Uganda, and Kakamega Nature Reserve, in Kenya.
Bibliography. Bennun (1994), Benson *et al.* (1971), Britton (1972, 1980), Byaruhanga *et al.* (2001), Carswell (1986), Cave & MacDonald (1955), Chapin (1953), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett *et al.* (2004), Everitt (1964a), Hall & Moreau (1970), Jackson & Sclater (1938), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1960, 1963, 1973), Mann (1985), Nikolaus (1987, 1989), Stevenson & Fanshawe (2002), Turner & Zimmerman (1979), Zimmerman (1972), Zimmerman *et al.* (1996).

62. Prigogine's Greenbul
Chlorocichla prigoginei

French: Bulbul de Prigogine **German**: Prigoginebülbül **Spanish**: Bulbul de Prigogine
Other common names: Congo/Butembo Greenbul

Taxonomy. *Chlorocichla prigoginei* de Roo, 1967, Maboya, on Upper Luhule River, Kivu, DRCongo.
May form a species pair with *C. laetissima*. Monotypic.
Distribution. NE DRCongo: Lendu Plateau (between Nioka and Djugu) and scattered localities between Beni and Butembo (NW of L Edward).



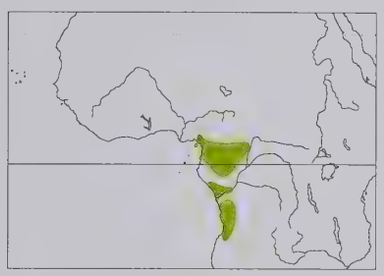
Descriptive notes. 19–20 cm. A medium-sized golden-olive greenbul. Lores and preorbital area are pale grey, feathers short, stiff and forward-pointing; eyering greyish-white, broad and somewhat contrasting; rest of head and whole of upperparts yellowish olive-green, wing feathers dark brown with yellowish olive-green outer webs, tail olive with yellowish olive-green margins; chin white, throat bright yellow; underparts greenish-yellow, side of breast and flanks darker and greener, undertail-coverts yellowish-brown; iris dark red; bill black; legs dull bluish-grey, dark horn or blackish. Differs from similar *C. laetissima* in smaller size, white (not yellow) chin, grey (not yellow) lores and preocular area, pale grey eyering. Sexes alike, female on average smaller than male. Juvenile undescribed. Voice. No information.
Habitat. Isolated forest patches in savanna, gallery forest along upper courses of rivers and thicket, at 1350–1800 m; not found in mature lowland forest.
Food and Feeding. Little information. Stomach of one individual contained seeds, fruit pulp and a caterpillar. One observed alone in understorey. On two occasions, single individual seen with group of *C. laetissima*, once a party of a dozen or so of latter foraging at 1–3 m beside a track, the second a group beside a small stream; on both occasions present species, in contrast to its relative, was silent and undemonstrative, with no wing-flicking. Noted to perch frequently on large leaves of unidentified bush.
Breeding. No information.
Movements. No information.
Status and Conservation. ENDANGERED. Restricted-range species: present in Albertine Rift Mountains EBA. Estimated to number fewer than 10,000 individuals, and to have a range size of only 870 km². Known solely from skins, except for some observations made over a two-day period in 1994 in a forest patch at Djugu (Lendu Plateau). Current status of forest in the Beni–Butembo area is unknown, but likely to be under serious threat from logging and agricultural encroachment. In 1997 only c. 20 ha of forest estimated to remain on the Lendu Plateau, and it is thought that even this may now have gone as a result of encroachment from surrounding villages. None of the localities from which the species has been recorded has any formal protection.
Bibliography. Butchart & Stattersfield (2004), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Demey *et al.* (2000), Dowsett (1985a), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Keith *et al.* (1992), Mackworth-Praed & Grant (1973), Pedersen (1997), Prigogine (1985), do Roo (1967), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

63. Yellow-bellied Greenbul
Chlorocichla flaviventris

French: Bulbul à poitrine jaune **German**: Gelbbauchbülbül **Spanish**: Bulbul Pechiamarillo
Other common names: Yellow-bellied Bulbul, Yellow-breasted Greenbul

Taxonomy. *Trichophorus flaviventris* A. Smith, 1834, near Durban, South Africa.
Has in the past been suggested as forming a superspecies with *C. falkensteini*, but subsequent studies have not supported such a relationship. Poorly differentiated race *ortiva* (described from S Mozambique) treated as a synonym of *occidentalis*. Three subspecies recognized.
Subspecies and Distribution.
C. f. centralis Reichenow, 1887 – S Somalia and SC & W Kenya S to E Tanzania and NE Mozambique.
C. f. occidentalis Sharpe, 1882 – NW Angola E to SE DRCongo and W Tanzania, S to extreme NW Namibia, N & E Botswana, N South Africa (S to Northern Province and Mpumulanga) and SC Mozambique.
C. f. flaviventris (A. Smith, 1834) – coastal S Mozambique S to E South Africa (S to KwaZulu-Natal and extreme N Eastern Cape).

Descriptive notes. 20–21·5 cm; male 34·5–52 g, female 32–41 g. A large, dark-headed greenbul with prominent white eyelids; crown feathers often erected into low shaggy crest. Nominate race has lores, cheeks and side of head dull olive-brown, contrasting white upper eyelid, narrower and less conspicuous pale lower eyelid; top of head and upperparts olive-brown, uppertail-coverts tinged rusty; wings olive-brown, flight-feathers edged yellowish-olive; tail olive-brown, sometimes tinged reddish; throat and underparts pale yellow, breast and flanks washed olive-grey; iris dark brown, red-brown or red; bill horn, blackish-horn or purplish-slate, paler cutting edges; legs grey or blackish. Sexes alike, female on average smaller than male. Juvenile is duller and paler than adult, eye grey or brownish; eyes become red after c. 6 months. Race *centralis* is duller and darker brown above than nominate, particularly on head, which contrasts with back; *occidentalis* is brighter overall, light olive-green above, greyer ear-coverts, top of head rather browner and darker, contrasting somewhat with back, rump paler, tail and flight-feathers edged green, brighter yellow below, breast washed brownish. Voice. Song of *centralis* a querulous, nasal "qui quaaa quer qua queree qwa", delivered slowly, notes evenly spaced and sometimes preceded with few low, quiet introductory notes; also "rrreek, rrreek, rrreek, yarr", alternating with continued chattering. Song of other races has similar buzzy quality but different rhythm, 4–6 notes on same pitch, also delivered slowly, "jit-jar-jeer-jeer-jar", "jit-jeer-jar-jui-jeeo", "jit-jeer-jui-jeeo" or "pao-pao-pao-pao", likened to yapping of small dog. Scolding a loud, repeated "pow", "paa" or "neh"; contact call a repeated "quar-tooa, quar-toar", changing to "kerr quar, kerr quar" or "thwank thwank" when summoning mate to food source. Two may call together asynchronously. During display a soft "chaacha".
Habitat. Evergreen and semi-deciduous forest of various types, including coastal forest, *Cryptosepalum* forest, gallery forest, dune forest, as well as riverine bush, coastal scrub, dense bush in wooded savanna; locally, in anthill thicket in miombo and mopane (*Colophospermum mopane*) woodland, drier thickets on hillsides, and even gardens. In forested areas favours thick undergrowth in edge habitats and dense second growth; rarely penetrates interior. Mainly found at low and medium elevations, but reaching 1700 m in Zambia and Malawi, and 2100 m in E Africa.
Food and Feeding. Fruit, including berries, and seeds and flowers; also insects. Nestling diet insects for first 3 days, then also berries and other fruit with hard seeds removed; fruits of *Allophylus*, *Carissa*, *Cissus*, *Clausena*, *Ficus*, *Lantana* and *Teclea* fed to young. Found in pairs or in groups of up to six individuals. Accompanies other bulbul species at fruiting trees; often joins mixed-species parties, and has been recorded as attending doryline ant swarms. Usually noisy, but often retiring and hard to see; will emerge early in morning to sun-bathe. Forages at all levels, but mainly in middle stratum and canopy in Zambia and Malawi; more often in lower strata in South Africa. Hawks insects in flight. Also perches on antelopes and grooms head, ears and eyes, presumably for ectoparasites; usually tolerated by antelope. Has also been recorded as pecking at preorbital glands of klipspringer (*Oreotragus oreotragus*), possibly seeking to ingest secretions.
Breeding. Nesting recorded in Mar–Aug in Kenya, Oct–Jan in W Tanzania, all months in DRCongo, Oct–Mar (mainly Nov–Jan) in Malawi, Sept–Feb in Zambia, Sept–Mar (mainly Oct–Dec) in Zimbabwe, Nov in Botswana, Oct–Jan in Mozambique, and Sept–Jan (mainly Oct–Dec) in South Africa; birds in breeding condition in Jan and Aug–Sept (and juvenile in Jun) in Angola and Mar in Mozambique. Monogamous. Solitary, territorial. In pre-copulatory behaviour following initial chase, female crouches and fans wings, male facing, both make soft calls, erect crown feathers, open bill, and rotate head asynchronously on elliptical course. Nest built by both sexes, in one instance completed in 7 days (in Kenya), a small, shallow, thin, loosely built cup of twigs, pieces of vine, tendrils, plants stems and grass, lined with tendrils, fine rootlets, grass blades and dead leaves, external diameter 8·5–10 cm and depth 4·5–5 cm, internal diameter 5·5–7·5 cm, cup depth 2·5–3·5 cm; placed 1–4 m above ground in fork in middle or canopy of small leafy shrub or near end of horizontal branch or among creepers, sometimes attached to support with cobwebs, usually (not always) well concealed by foliage. Clutch usually 2 eggs, sometimes 1 or 3; incubation by female only, fed at nest by male, period 14 days; chicks fed by both parents, male also broods, nestling period c. 16 days.
Movements. Little information. Thought to be sedentary.
Status and Conservation. Not globally threatened. Widespread and generally common. Population in S Mozambique thought to exceed 40,000 individuals; 4 pairs in 16 ha in C Kenya. Well represented in protected areas.



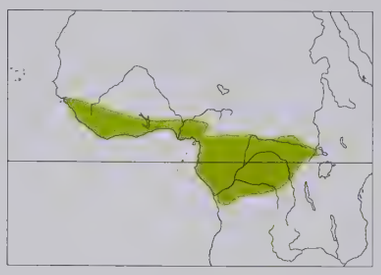
Bibliography. Ash & Miskell (1983, 1998), Benson & Benson (1977), Benson *et al.* (1971), Britton (1972, 1980), Brown & Britton (1980), Buchan *et al.* (2000), Chalton (1976), Chapin (1953), Clancey (1964, 1996), Dean (2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett *et al.* (2004), Dowsett-Lemaire (1989), Dowsett-Lemaire & Dowsett (2004), Frost (1979), Ginn *et al.* (1989), Hall & Moreau (1970), Hanmer (1978), Irwin (1981), Jackson & Sclater (1938), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louw (2005b), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993), Mlingwa (1998), Mlingwa & Bairlein (1998), Oatley *et al.* (1997), Parker (1999), Penry (1994), Roberts (1993, 1995), Skinner (1995), van Someren (1956), Stevenson & Fanshawe (2002), Steyn (1975), Tarboton (2001), Turner & Zimmerman (1979), Vernon (1972b), Vincent, A.W. (1947), Vincent, J. (1935a), Willis (1983), Zimmerman *et al.* (1996).

64. Falkenstein's Greenbul

Chlorocichla falkensteini

French: Bulbul de Falkenstein **German**: Falkensteinbülbül **Spanish**: Bulbul de Falkenstein
Other common names: Yellow-necked/Yellow-throated Greenbul

Taxonomy. *Criniger Falkensteini* Reichenow, 1874, Chinchoxo, Loango Coast, Cabinda, Angola.
Has in the past been suggested as forming a superspecies with *C. flaviventris*, but subsequent studies have not supported such a relationship. Monotypic.
Distribution. Three apparently disjunct populations: SW Cameroon E to W Central African Republic and S to SC Gabon; S PRCongo, N Angola (Cabinda) and extreme SW DRCongo; and W Angola (Uige S to Huíla).



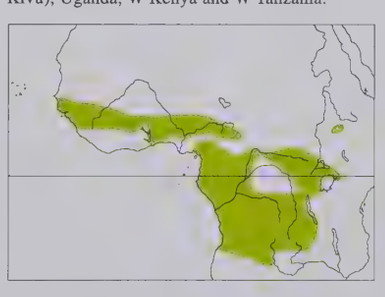
Descriptive notes. 18–20 cm; male 37–41 g, female 29–37 g. A medium-sized greenbul with conspicuous yellow throat. Has lores and fore cheeks darkish grey; rest of head, including rear cheeks and ear-coverts, side of neck and whole of upperparts, including wings and tail, bright olive-green; carpal area yellow; chin and throat bright lemon-yellow, this colour extending a little way onto side of neck; underparts pale grey, becoming creamy on belly, washed yellowish-olive on undertail-coverts and thighs; underwing-coverts and axillaries sulphur-yellow; iris dark red, crimson or orange-red; bill black or dark greenish-grey; legs blue or blue-grey. Distinguished from *C. flaviventris* by being grey (not yellow) below, and by lacking eyering; from *C. flavicollis* by smaller size, green (not brown) upperparts, red (not pale) eyes. Sexes alike, female on average smaller than male. Juvenile resembles adult, but gape yellow, eyes light brown. Voice. Song a string of 6–10 nasal notes, "kik-kuk-ku-kwéé-uk-wik-e-wik-kup", or "kip-kop-ko-kwéé-ko-witawit-kup", with some variations; reminiscent of songs of *C. flaviventris* and *C. simplex* in quality. Chattering calls similar.
Habitat. Isolated forest patches, dense secondary growth, riparian woodland and thicket; avoids forest proper. Favours secondary and anthropogenic habitats, such as clearings and other edge situations, abandoned farmland, fallows, banana plantations, regenerating coffee plantations, deserted villages and gardens.
Food and Feeding. Berries and other fruit, including *Ficus*, *Rauwolfia*, *Solanum*, *Trema* and small peppers; also insects, such as alate termites (Isoptera) and caterpillars. Occurs in pairs or small family parties; occasionally joins mixed-species flocks. Forages in vegetation of small and medium-sized trees and bushes. Often stays hidden, when presence revealed by frequent vocalizations; at other times, will frequently jump out on to exposed perches and call while raising each wing alternately (yellow underwing-coverts) and flicking tail. Territorial all year; in Gabon, present species, *C. flavicollis* and *C. simplex* seem to exclude one another locally.
Breeding. Nesting recorded in May and Jul in Cameroon; Nov in Gabon, where flying young seen Jun, nest-building Jan and Mar, and most vocal Sept–Feb; birds in breeding condition in Oct and juveniles with traces of down in Jan in Angola. Territorial. Only one nest described, built by presumed female, accompanying mate singing, a shallow cup of bark fragments and leaf stems, lined with fine grasses, internal diameter 5·5 × 6·5 cm, in fork of bush. Clutch 2 eggs; incubation by female only; no information on inclubation and nestling periods; fledglings fed with caterpillars by both parents.
Movements. Sedentary, at least in Gabon.
Status and Conservation. Not globally threatened. Locally common to rare. Density in Gabon up to 12–15 birds/ha in places, but often much lower. Occurs in a number of protected areas, including Campo Ma'an National Park, in Cameroon, Dzanga-Ndoki National Park, in Central African Republic, Lopé National Park, in Gabon, Odzala National Park, in PRCongo, Bombo-Lumene Game Reserve, in DRCongo, and Quiçama National Park, in Angola.
Bibliography. Borrow & Demey (2001), Brosset (1971a), Brosset & Érard (1986), Chapin (1953), Chappuis (1975), Christy & Clarke (1994), Dean (2000), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1991), Fishpool & Evans (2001), Germain & Cornet (1994), Hall & Moreau (1970), Keith *et al.* (1992), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1963, 1973), Sargeant (1993), Schouteden (1957).

65. Simple Greenbul

Chlorocichla simplex

French: Bulbul modeste **German**: Hartlaubbülbül **Spanish**: Bulbul Sencillo

Taxonomy. *Trichophorus simplex* Hartlaub, 1855, River Boütry, Ghana.
Monotypic.
Distribution. SE Guinea-Bissau E to extreme S Sudan and W Uganda, S to N Angola and C & NE DRCongo.
Descriptive notes. c. 21 cm; male 41–54·5 g, female 40–49 g. A large greenbul with conspicuous white throat and white eyering. Has blackish lores, some indistinct paler streaking on cheeks and ear-coverts, contrasting white broken eyering broader above eye than below it; rest of head and whole of upperparts, including wings and tail, dark brown, tail and flight-feathers edged olive; throat and malar region white, breast and flanks light olive-brown, lower flanks washed buffy, centre of belly creamy white or yellowish-buff, undertail-coverts buff; iris dark brown or reddish-brown; bill black, paler cutting edges; legs dark grey or bluish-slate. Distinguished from *C. flavicollis* (of race *soror*) by contrasting eyering, dark eyes, overall darker coloration above, also by voice. Sexes alike, female on average smaller than male, with redder iris. Juvenile undescribed. Voice. Song a subdued nasal chattering of 8–12 notes, starting quietly and increasing in volume, third note from last typically highest and loudest, "wido, wida-wit-do, wida-kwít-to-kwair". Chattering, burry "kurra-kurra-kurra" thought to be contact call; also has scolding, nasal "churrk-churrk" or "wherr", and short, clipped "kwit!".



Habitat. Thick bush of various sorts, including orchard-bush, dense shrubs in savanna, thickets, gallery forest, farmbush and forest edge in the forest zone and forest–savanna mosaic; avoids forest proper. Readily adapts to secondary growth around farmland, fallows, cassava fields, large clearings, village margins and other degraded habitats, but not along edges of logging roads in forest. Mainly lowlands, but recorded to 1500 m in Liberia.
Food and Feeding. Fruit, including particularly *Solanum*, also *Rauwolfia*, *Trema*, palms and red peppers; also seeds; also arthropods, such as alate termites (Isoptera), caterpillars, spiders (Araneae). Typically in pairs or small family groups; occasionally joins mixed-species flocks. Generally rather shy and skulking, staying within thick vegetation, and revealing its presence by its voice; will perch in the open at times. Territorial throughout year; defends area of 1–2 ha in Gabon, where present species, *C. flavicollis* and *C. falkensteini* seem to exclude one another locally.
Breeding. Nesting recorded in Mar in Sierra Leone, Feb and Apr (also nest-building Jul, Dec) in Ghana, Jan and Jun–Sept in Nigeria, Jan, Mar, Jun–Sept and Dec in Cameroon, Sept–Feb (peak Jan, once Jul in unusual year) in Gabon, and Aug and Oct–Mar in DRCongo; birds in breeding condition Feb and Jun–Nov (fledglings Oct–Nov, independent young Dec–Feb) in Liberia and Sept–Dec and Feb in Central African Republic. Territorial. Nest a small, shallow cup, thin and compact but strong, made of twigs, rootlets, plant stems, dry grasses, vines and other fibrous matter, bound together with cobwebs and unlined, external diameter 8–11 cm, depth 8–11 cm, internal diameter 5–7 cm and cup depth 4 cm, placed 0·9–2 m above ground in fork of dense clump of bushes or saplings (native or introduced); of twelve nests in Gabon, eight built in *Solanum* and one each in *Trema*, *Harungana*, in middle of cassava crop and in ornamental hedge; elsewhere, nests recorded in *Triumfetta*. Clutch 2 eggs, sometimes 1; incubation by female only; no information on incubation and fledging periods. In Gabon, three eggs of 24 laid were infertile, and seven of eleven nests were robbed.
Movements. Sedentary, at least in Gabon.
Status and Conservation. Not globally threatened. Widespread, and locally common to abundant. This species' propensity for occupying anthropogenic habitats means that it is unlikely to become of conservation concern. Occurs in numerous national parks, including those of Sapo, in Liberia, Taï Forest, in Ivory Coast, Kakum, in Ghana, Cross River, in Nigeria, Korup, in Cameroon, Lopé, in Gabon, Nouabalé-Ndoki, in PRCongo, Virunga, in DRCongo, and Semliki, in Uganda.
Bibliography. 66. Yellow-throated Greenbul

Chlorocichla flavicollis

French: Bulbul à gorge claire **German**: Gelbkehlbülbül **Spanish**: Bulbul Gorgiamarillo
Other common names: Yellow-throated Leaflove

Taxonomy. *Haematornis flavicollis* Swainson, 1837, West Africa.
Despite generic placement, appears on basis of voice and behaviour to be closest to *Thescelocichla leucopleura* and *Pyrrhurus scandens*. Has been suggested that nominate race and *soror* may represent two different species, as the two occur to within 50 km of each other in Cameroon, but with no intergrades known; in addition, some vocal differences exist, and nominate in Mali recently shown not to respond to playback of song of *soror*; further study needed. Racial identity of population in NW Central African Republic uncertain, tentatively placed in nominate. Proposed race *simplicicolor* (E Cameroon) considered not safely distinguishable from *soror*; *pallidigula* (described from Entebbe, in Uganda) on average rather darker overall than *flavigula*, but not satisfactorily separable from it. Three subspecies recognized.
Subspecies and Distribution.
C. f. flavicollis (Swainson, 1837) – Senegambia and SW Mali E to Nigeria, N Cameroon (Adamaoua Plateau) and NW Central Africa Republic, S to Sierra Leone, N Ivory Coast, SE Ghana and S Benin.
C. f. soror (Neumann, 1914) – NC Cameroon (Tibati) E to S Central African Republic and SW Sudan, S to PRCongo and C DRCongo (S to N Kasai and N Maniema); also WC Ethiopia.
C. f. flavigula (Cabanis, 1880) – Angola, SE & E DRCongo (S from S Kasai, S Maniema and Kivu), Uganda, W Kenya and W Tanzania.

Descriptive notes. c. 22·5 cm; male 46–60 g, female 37–47 g (*flavigula*). A large, noisy non-forest bulbul with conspicuous, contrastingly coloured throat and pale eyes. Male nominate race has lores, cheeks and ear-coverts olive-brown; top of head dark greyish olive-brown with dark feather centres (appearing scaly, most obviously so on forehead and forecrown); upperparts, including wings and tail, dark olive-brown, flight-feathers and tail feathers edged greenish-olive; throat bright sulphur-yellow; underparts greyish olive-brown, paler than upperparts, some scattered yellowish streaking, breast feathers with grey tips, lower belly and undertail-coverts brown; iris dull yellow, creamy-buff, grey-buff or pale brown; bill black; legs grey or dark grey. Female is on average smaller than male. Juvenile is darker overall than adult, but throat whitish. Race *soror* distinctive, has throat white with only a trace of yellow, underparts somewhat greyer, also upperparts on average greyer in N parts of range, browner in S; *flavigula* has paler yellow throat than nominate (brighter in E of range), underparts brownish or

greenish-olive in E, greyer in W, but with whitish shaft streaking throughout, belly centre paler than nominate, pale brown, creamy or pale yellowish, undertail-coverts pale brown. Voice. Song a string of harsh, nasal, grating "chow" or "kio" notes interspersed with shorter notes, similar in quality to that of *Pyrrhurus scandens* and *Thescelocichla leucopleura*; some racial variation, e.g. "kion-kio-kio-kio-kio" (nominate), "chow, chow, ch-ch-chow", "chow, chi-chu-chu, chow, chow" (*soror*) or "skyow-skyow-chyow-chyow, ch-ch-ch-ch-ch-ch" (*flavigula*). Contact calls include loud, rasping, nasal "chow", and "tchwaa, tchwaa" and shorter "kyip", given by group-members while foraging.

Habitat. Wooded and bushy habitats away from forest, including open woodland, gallery forest, orchard-bush, thickets, riparian bushes and scrub. In forested areas may occur in clearings and some drier types of second growth, but does not penetrate interior. Readily adapts to anthropogenic habitats such as abandoned cultivation, *Lantana* thicket, plantations, orchards, parks, wooded gardens and mango trees. Also found at edges of *Papyrus* swamps, sometimes entering them. Lowlands and medium elevations, but to 1800 m in Cameroon, 2000 m in DRCongo; to 2300 m, but mainly below 1500 m, in E Africa.

Food and Feeding. Fruit, including *Rauwolfia*, *Solanum*, *Trema*, guava, mango, red pepper; also some insects, including beetles (Coleoptera) and caterpillars. Almost always found in small family parties, less often in pairs or alone. Members of group often move in close succession, one landing on perch just vacated by another. Forages mostly at low levels, including on ground, but rises to middle and upper middle levels in taller trees. Rather shy, but will emerge on to vantage points periodically to look around. Highly vocal while foraging; scolds frequently, often accompanied by puffing-out of crown and throat feathers and wing-flicking. In Gabon, present species, *C. simplex* and *C. falkensteini* seem to exclude one another locally.

Breeding. Nesting recorded in Jul and Nov–Dec in Gambia, Nov in Mali, May–Aug in Nigeria, Dec in PRCongo, Dec–Jul (breeding condition Sept–Oct) in DRCongo, Oct–Dec in Rwanda, Sept in Sudan, Dec–Jun and Aug–Sept (peaks in long rains and dry season) in Uganda and W Kenya, and Sept–Feb (peak Oct–Nov) in Zambia; birds in breeding condition in Aug–Sept and Jan and juvenile in Jun in Angola. Thought to be co-operative breeder; in Gabon, groups of three individuals, believed not necessarily to comprise a pair and young, jointly defend territory. Nest built by only one of pair, presumed female, while mate watched, construction took 10 days (first egg laid 2 days later), presumed male subsequently drove off all birds approaching site; nest a cup of small twigs, rootlets, leaf stems and dry leaves, bound together with cobwebs, in one case lined with *Casuarina* leaves, placed 2–10 m above ground in tree fork formed by small branches or junction of palm leaves, or suspended between fork twigs of horizontal branch, usually in tree with dense foliage (e.g. mango); frequently in suburban location such as garden or compound, often close to buildings. Clutch 2 eggs; no information on incubation and nestling periods. Known host of Red-chested Cuckoo (*Cuculus solitarius*).

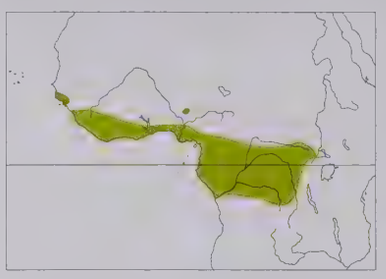
Movements. Sedentary, at least in Gabon.

Status and Conservation. Not globally threatened. Status varies; considered scarce, not uncommon, common or locally abundant in different parts of its extensive range. Given this species' habitat preferences, and the fact that it does not require undisturbed forest, its future seems assured. Well represented in protected areas.

Bibliography. Ash (1973a, 1977), Bannerman (1936, 1953), Barlow *et al.* (1997), Benson *et al.* (1971), Borrow & Demey (2001), Britton (1972, 1980), Brosset (1971a), Brosset & Érard (1986), Brown & Britton (1980), Carswell (1986), Cave & MacDonald (1955), Chapin (1953), Chappuis (1975), Cheke & Walsh (1996), Christy & Clarke (1994), Dean (2000), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett *et al.* (2004), Dowsett-Lemaire & Dowsett (1991), Elgood *et al.* (1994), Fishpool *et al.* (1994b), Gore (1990), Grimes (1987), Hall & Moreau (1970), Jackson & Sclater (1938), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1960, 1963, 1973), Morel & Morel (1990), Nikolaus (1987, 1989), Prigogine (1971, 1978, 1984), Rand (1958), Rodwell (1996), Sargeant (1993), Schouteden (1957), Stevenson & Fanshawe (2002), Thiollay (1985), Turner & Zimmerman (1979), Urban & Brown (1971), Zimmerman *et al.* (1996).

Genus *THESCELOCICHLA* Oberholser, 1905

67. **Swamp Palm Bulbul**



Thescelocichla leucopleura

French: Bulbul des raphias **German**: Raphiabülbül **Spanish**: Bulbul de las Rafias
Other common names: White-tailed/Swamp Greenbul

Taxonomy. *Phyllostrophus* [*sic*] *leucopleurus* Cassin, 1855, Moonda River, Gabon.

A distinctive species; on basis of bill shape, voice and behaviour, appears closest to *Pyrrhurus scandens* and *Chlorocichla flavicollis*. Monotypic.

Distribution. S Senegal, Guinea-Bissau and E Guinea E, including isolated population in C Nigeria (Jos Plateau), to extreme W Uganda, S to PRCongo, N Angola (Cabinda) and E DRCongo.

Descriptive notes. c. 23 cm; male 61–67 g, female 58–60 g. A large, conspicuous and distinctive bulbul. Lores, cheeks and ear-coverts are olive-brown with conspicuous white centres and shaft streaking, giving speckled and streaked effect to side of head, eyering whitish; top of head and entire upperparts, including wings, olive-brown, crown feathers fringed dark (scaly appearance); tail olive-brown, outer four pairs of feathers broadly tipped white, white increasing from c. 15 mm on T3 to 30 mm on T6; throat off-white, upper breast pale grey-buff with white shaft streaking, rest of underparts creamy white; iris brown, red-brown or reddish; bill black, lower mandible paler, tinged greyish or bluish; legs dark grey-brown, grey or bluish-grey. Sexes alike, female on average smaller than male. Juvenile is browner above, throat and breast pale yellow. Voice. Most common vocalization a raucous nasal cackling made by foraging flock, begins quietly, in fairly low register, but rapidly increases in volume and becomes higher and more shrill, "kokoko...eeko-rít-toto-tréé-tu-trít-toro", likened to a tape-recorded conversation played too fast; as one bird starts, it immediately provokes other flock-members to join in; these outbursts end abruptly, but are repeated after silence of c. 10–20 seconds. Song similar, given by single individual, often in two parts, increasing in volume, "ti-tu-to-trít-to...ti-to-réé-to-ráá". Call a penetrating, nasal chattering on even pitch, "cha-cha-cha-cha".

Habitat. Swampy forest areas with palm trees, particularly *Raphia*, to lesser extent, *Elaeis*, in lowland forest zone; also areas outside forest but with palms, less often in drier forest, such as around clearings; sometimes in *Pandanus*. Penetrates forest–savanna mosaic and gallery forest in some places; also cacao plantations, as well as cultivation with mature fruit trees, where close to forest. Sea-level to 800 m in Liberia, to 1050 m in Cameroon and 1100 m in DRCongo.

Food and Feeding. Fruit, including *Ficus*, *Heisteria*, *Macaranga*, *Morinda*, *Musanga*, *Schleffera*, *Trichilia*, peeled palm nuts, bananas, and seeds; also insects such as caterpillars, alate termites (Isoptera), ants (Hymenoptera). Occurs in voluble monospecific groups of 3–10 individuals, sometimes more. Rarely joins multi-species flocks; occasionally follows *Dorylus* ant swarms. Forages at all levels, from ground (occasionally) to tops of palms, and up to 20 m in high forest. Moves rapidly, using vertical to horizontal perches, gleaning items from foliage, tangles of dead leaves, epiphytic plants, lianes, etc., working over bark, often clinging to trunks, or taking prey items off them while hovering.

Breeding. Nesting recorded in Feb in Ghana, Feb, May and Jul (and in breeding condition in Sept–Oct) in Cameroon, and Jan, Mar–Apr and Aug–Sept in Gabon; birds in breeding condition in Jun–Jul in Liberia and Nov in DRCongo. Thought to be a co-operative breeder; in Gabon, 3–4 birds gave alarm calls simultaneously at presence of intruder, and two young leaving nest observed to be fed by four different adults. Territory defended by loud chorusing by all group-members, and displays involving spreading of wings and tail. Only one nest described, made of long strips of half-rotten leaves, built 2 m above ground in banana tree in abandoned plantation; known also to nest in swamp palms; territory a few hectares in palm swamps, 12–15 ha in suboptimal habitat (e.g. edges of cultivation in Gabon). Clutch 2 eggs; incubation by female only, young fed by both parents, no information on duration of incubation and nestling periods.

Movements. Largely sedentary; some nomadism recorded.

Status and Conservation. Not globally threatened. Widespread and, in suitable habitat, common. Recorded in numerous protected areas including Marahoué National Park, in Ivory Coast, Kakum National Park, in Ghana, Okomu National Park, in Nigeria, Mbam-Djerem National Park, in Cameroon, Lopé National Park, in Gabon, Odzala National Park, in PRCongo, Salonga National Park, in DRCongo, and Semliki National Park, in Uganda.

Bibliography. Genus *PYRRHURUS* Cassin, 1859

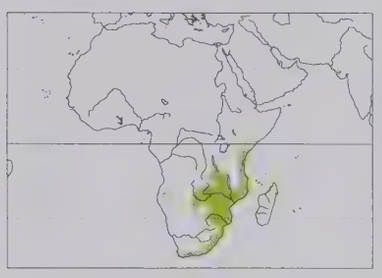
68. **Leaf-love**

Pyrrhurus scandens

French: Bulbul à queue rousse **German**: Uferbülbül **Spanish**: Bulbul Colirrojizo
Other common names: African/Common Leaflove

Taxonomy. *Phyllastrephus scandens* Swainson, 1837, West Africa.
Often included in *Phyllastrephus*, and has even been suggested as forming a superspecies with two members of that genus (*P. fischeri* and *P. cabanisi*), but relationship seems remote and, further, it differs in plumage and colour pattern. On basis of bill shape, voice and behaviour, appears more closely allied to *Thescelocichla leucopleura* and *Chlorocichla flavicollis*. Until more is known of its affinities, it seems preferable to retain present species in its own, monotypic genus. Proposed races *acedis* (described from R Ogobai, in Gabon) and *upembae* (S DRCongo) considered not satisfactorily distinguishable from *orientalis* (former on average darker above with more rufous tail, latter with paler browner tail). Two subspecies recognized.
Subspecies and Distribution.
P. s. scandens (Swainson, 1837) – Gambia and SW Senegal, E Guinea-Bissau and W Guinea E to N Cameroon.
P. s. orientalis (Hartlaub, 1883) – N Cameroon E to extreme S Sudan, and S to S PRCongo and W & S DRCongo (scattered localities in Kwango, Kasai and Katanga); also C Uganda, extreme NE Rwanda and extreme W Tanzania.

Descriptive notes. c. 22 cm; male 61–67 g (nominate), male 43–53 g, female 33–51 g (*orientalis*). Large, handsome distinctively coloured bulbul, feathers of lower back and rump long and loose. Nominate race has pale grey-olive lores, non-contrasting and rather inconspicuous creamy-white eyering, light brownish-grey ear-coverts with indistinct paler shaft streaking; top of head and neck olive-grey, mantle, back, scapulars and lesser wing-coverts brownish olive-green, rump paler and more chestnut, uppertail-coverts brighter chestnut; wings brown, edged rufous on flight-feathers; tail pale rufous-chestnut ; throat white, breast and flanks dirty buff, lower flanks washed cinnamon, lower breast and belly creamy buff; iris reddish-brown, greyish-brown or bluish-grey; upper mandible dark horn, olive-green or bluish-grey, lower mandible whitish or pale grey, cutting edges and tip whitish to yellowish; legs blue-grey, pale pinkish-grey or pale olive-green. Sexes alike, female on average smaller than male. Juvenile resembles adult, but upperparts washed russet, throat washed grey, underparts white. Race *orientalis* is smaller than nominate, greyer above, slightly paler below. Voice. Song begins with a few subdued nasal notes, "kawp, kawpa", then bursts into loud, rapid, exuberant, pleasing, conversational cackling, "kyop-kee-kyop-kyop-ke-kyop", is uttered repeatedly by family groups in chorus. Variations include sharp, high-pitched "chip-chip-chip-chip-chip" repeated by one or more individuals, others joining occasionally with hoarse "karp" or "koko".
Habitat. Marked preference for waterside habitats; forest fringing rivers, gallery forest and thicket, also forest patches in savanna and orchard-bush. In forest zone proper, normally found only in areas of *Raphia* swamp; absent from wetter forest types in some areas (e.g. Upper Guinea and parts of DRCongo). From sea-level to 1200 m; to 1500 m on Mt Nimba, in Liberia.
Food and Feeding. Arthropods, including grasshoppers (Orthoptera), beetles (Coleoptera), caterpillars, termites (Isoptera); also small gastropods, berries and seeds. Occurs in pairs or, more usually, small groups; regularly joins mixed-species parties. Forages energetically and acrobatically at all levels, but mainly in middle and upper strata. Gleans from foliage, clumps of dead leaves, crevices, tree trunks, lianes, etc., and makes short aerial sorties to catch flushed prey and alate termites; also explores leaf litter and exposed roots on ground. Flicks and shivers tail.
Breeding. Nesting recorded in Oct in Sudan, Jan in Liberia, Dec–Feb in Ghana, Dec–Jan in Cameroon and Oct–Nov in DRCongo; carrying nesting material in Mar in Togo; birds in breeding condition in Oct–Nov in Nigeria, Jun in Central African Republic and Apr and Jul in Uganda. Territorial. Nest cup-shaped, made of dry leaves, grass and strips of palm frond, unlined, one had internal dimensions of 6 × 7 cm; suspended from small branches of bush or tree overhanging stream, attached by cobwebs and black hair-like fibres which form net around exterior of nest. Clutch 2–3 eggs; incubation by female only; no information available on incubation and nestling periods.
Movements. Resident, so far as known.
Status and Conservation. Not globally threatened. Locally common; has large range, but distribution fragmented. At least some gaps in its distribution are real, as it is not an easy species to overlook. Density estimated at 1 group/3 ha of gallery forest in Semliki (Uganda). Occurs in numerous national parks, including those of Haute Niger, in Guinea, Marahoué, in Ivory Coast, Kakum, in Ghana, Okomu, in Nigeria, Mbam-Djerem, in Cameroon, Lopé, in Gabon, Odzala, in PRCongo, Salonga, in DRCongo, and Semliki, in Uganda.
Bibliography. Bannerman (1936, 1953), Barlow *et al.* (1997), Borrow & Demey (2001), Britton (1972, 1980), Brosset (1971a), Brosset & Érard (1986), Carswell (1986), Cave & MacDonald (1955), Chapin (1953), Chappuis (1975), Cheke & Walsh (1996), Christy & Clarke (1994), Claffey (1995), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1991), Elgood *et al.* (1994), Fishpool & Evans (2001), Fishpool *et al.* (1994b), Gatter (1997), Gore (1990), Grimes (1987), Hall & Moreau (1970), Keith *et al.* (1992), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1960, 1973), Morel & Morel (1990), Nikolaus (1987, 1989), Rossouw (2001), Sargeant (1993), Schouteden (1957), Stevenson & Fanshawe (2002), Thiollay (1985).



Genus *PHYLLASTREPHUS* Swainson, 1831

69. **Terrestrial Brownbul**

Phyllastrephus terrestris

French: Bulbul jaboteur **German**: Laubbülbül **Spanish**: Bulbul Terrestre
Other common names: Terrestrial Bulbul, Bristle-necked Brownbul

Taxonomy. *Phyllastrephus terrestris* Swainson, 1837, Outeniekwa Forest, Western Cape, South Africa.
Race *suahelicus* intergrades clinally with *intermedius* in Malawi and N Mozambique. Poorly marked race *bensoni* (described from lower Meru Forest, in Kenya) is treated as a synonym of *suahelicus*; similarly, *katangae* (extreme SE DRCongo) synonymized with *intermedius*. Three subspecies currently recognized.
Subspecies and Distribution.
P. t. suahelicus Reichenow, 1904 – S Somalia and C & E Kenya (Meru and Chuka forests, Mt Kenya, coast) S to N Mozambique.
P. t. intermedius Gunning & Roberts, 1911 – SE DRCongo, Zambia, Malawi and N Mozambique S to N Botswana, Zimbabwe and NE South Africa (S to E KwaZulu-Natal); isolated population in SW Angola.
P. t. terrestris Swainson, 1837 – Swaziland and E & S South Africa (W KwaZulu-Natal S along coastal fringe to Western Cape).

Descriptive notes. 20–22 cm, 33–47 g (nominate); 17–19 cm, male 29·5–44 g, female 24·5–38 g (*intermedius*); 17–19 cm, male 31–40 g, female 25–34 g (*suahelicus*). A large brown and white bulbul. Nominate race has ill-defined blackish line from lores to behind eye, olive-brown cheeks and ear-coverts with some paler streaking, narrow, relatively inconspicuous whitish broken eyering; top of head and upperparts, including wings, dark olive-brown, lower back to uppertail-coverts and tail warm gingery brown; throat white, upper breast and flanks olive-brown, lower breast and belly creamy, lower flanks and undertail-coverts buffy olive; iris red, red-brown or golden-brown; bill blackish-horn, paler lower mandible and cutting edges; legs slate-grey to silvery grey or brownish-horn. Differs from *P. strepitans* in duller, more olive-tinged upperparts, lacking reddish tones, and paler legs. Sexes alike, female on average smaller than male. Juvenile is somewhat paler and brighter. Race *intermedius* is smaller than nominate, has paler, brownish-olive upperparts, rusty-tinged brown rump, uppertail-coverts and tail, paler below, side of breast and flanks less contrasting, lower breast and belly white; *suahelicus* is same size as previous, but differs in having flanks browner, less grey, white underparts with faint buffy wash, upperparts with slight reddish wash, rump and tail slightly darker red, legs pale greyish-lavender, greyish-pink or light purplish-grey. Voice. Song a rough chattering of 4–10 low, burry, husky notes, all on one pitch (lower than that of *P. strepitans*), e.g. "chrrrrk, chrrk-chrrk, chrrrrk", "tchr tchr tcheerr tcheerr tchr tchr", or similar; intervals between phrases 4–10 seconds, sometimes punctuated by quiet, conversational "chut" or "chudut". When foraging, a continuous chattering of harsh churring notes, e.g. "prrrp-prrrp-prrrp-prrrrp", "warrarak-warra" or "wark-wark wárk"; foraging pair may from time to time break into rough duet, the churring notes speeding up and rising in pitch to become a short, harsh trill interspersed with some pure, shrill notes.
Habitat. Variety of thickly vegetated habitats, including evergreen forest (mostly lowland and coastal, occasionally montane), riparian forest, riverine bush, thickets, thick scrub, dense woodland and abandoned cultivation. From sea-level to 1500 m in South Africa (KwaZulu Natal); to 1750 m, exceptionally 2050 m, in Malawi, and 1400 m in Kenya.
Food and Feeding. Arthropods, particularly ants (Hymentoptera), grasshoppers (Orthoptera), beetles (Coleoptera), termites (Isoptera); also gastropods, small lizards; some fruit and seeds. Usually found in small groups; attends *Dorylus* ant swarms, and joins mixed-species flocks. Skulking and often hard to see, generally staying within cover; members of group cross open spaces reluctantly, one by one. Generally at or near ground level, where scratches about in leaf litter with the bill and feet and probes into vegetable debris. Also forages in bunches of dead leaves in creeper tangles to height of 7–12 m. Frequently flicks both wings together, combined with rapid tail-pumping. Has been recorded as gleaning ticks off red duiker (*Cephalophus natalensis*).
Breeding. Nesting recorded in Jan and Aug in Kenya, Oct–Apr (mainly Nov–Jan) in Zambia, Sept and Dec–Apr (mainly Dec–Feb) in Malawi, Oct–Apr in Mozambique, Sept–Feb and Apr (mainly Nov–Dec) in Zimbabwe, Oct and Dec in Botswana and Oct–Jan in South Africa; birds in breeding condition in Nov–Dec in Angola; possibly double-brooded. Monogamous. Solitary nester; territorial. Nest, reportedly built by both sexes, a shallow, flimsy and untidy cup of dark twigs, skeletonized leaves, dark stringy tendrils, roots, bark, moss and lichen, lined with rootlets, fine fibres and a few leaves, external diameter 8·5–9 cm, depth 3·5–6 cm, internal diameter 5–6·5 cm, depth 2–3 cm; usually 1–2 m above ground on branch or slung in fork, usually in dark tangle near edge of bush or thicket; nests in successive years built within c. 1–2 m of previous year's site. Clutch 1–4 eggs, usually 2; incubation by both sexes, period 13 days; chicks fed by both parents, at one nest only one adult seen to brood very young chicks (for periods of up to half an hour between foraging trips); no information on duration of nestling period.
Movements. Thought to be largely sedentary; of 62 individuals ringed in Zimbabwe, 38 recaptured at same place c. 7–8 times. Suspected that birds at highest altitudes in Malawi (2050 m) and Zimbabwe are wanderers.
Status and Conservation. Not globally threatened. Generally common, but local in parts of its range. Estimated densities in Swaziland 3 birds/100 ha in acacia (*Acacia*) savanna, 19 birds/100 ha in broadleaf woodland and 330 birds/100 ha in riverine forest; in Knysna Forest, in South Africa,

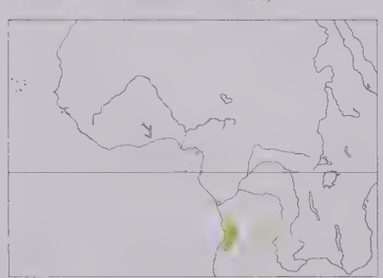
70. **Northern Brownbul**

Phyllastrephus strepitans

French: Bulbul brun **German**: Schillingsbülbül **Spanish**: Bulbul Pardo

Taxonomy. *Criniger strepitans* Reichenow, 1879, Malindi, Kenya.
Monotypic.
Distribution. SE Sudan, S Ethiopia, S Somalia, N & NE Uganda, Kenya and NE Tanzania; isolated population in W Sudan (Jebel Marra).



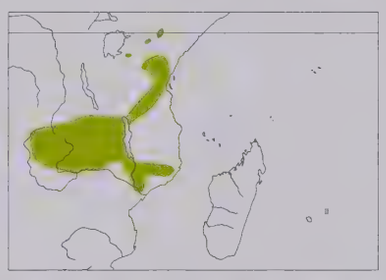
Descriptive notes. 15–18 cm; male 19–29 g, female 17–24 g. A medium-sized, predominantly brown pycnonotid, undistinguished in appearance, tail rather more graduated than that of most congeners. Lores and cheeks are pale grey-brown, ear-coverts pale brown with ill-defined narrow paler streaking; obscure darker line immediately in front of and behind eye, contrasting narrow white broken eyering; top of head and upperparts warm reddish-brown, rump and uppertail-coverts bright rufous, tail reddish brown; wings rufous-brown; throat white or pale buff, breast and flanks grey-brown, variably washed buff, lower breast and belly white, lower flanks, undertail-coverts and thighs buff; iris brown, red-brown or pale stone; bill black, paler lower mandible, cutting edges and tip; legs bluish-black or bluish-grey. Differs from *P. terrestris* in smaller size, brighter and more reddish-brown upperparts lacking olive tones, duller throat, darker legs; from *P. cerviniventris* also in warmer reddish upperparts, paler underparts, dark bill, legs and eye; from *P. cabanisi* in concolorous tail and back, dark eyes; from *P. fischeri* in dark eyes. Sexes alike, female on average smaller than male. Juvenile has top of head and back duller, eye dull brown. Voice. Song a harsh, rapid chatter, penetrating and insistent, "skrrrk-skrrrk-kk-kk-kk-kk-kk…" or "chichichichichichi-chk, chik-chik-chik…", often by pair in duet or by several together, often preceded and concluded by some slower, softer notes; reminiscent of *Turdoides* babbler, higher-pitched and faster than that of *P. terrestris*, often extended, interrupted with brief pauses every 10 seconds or so. Quieter contact calls when foraging.
Habitat. Forest edge, open woodland, wooded grassland, evergreen and deciduous thicket, riverine bush and scrub; from sea-level to 1600 m, mainly below 1000 m.
Food and Feeding. Insects and fruit, including *Lantana* and *Rhus*. Occurs in pairs or small groups; members of group cross open spaces one after the other. Has been recorded in mixed flocks with *P. cerviniventris*. Shy, forages low down in undergrowth; mean height of 1·2 m recorded in study in Kenya. Gleans from leaves, plant stems, the ground; also makes aerial sallies. Flicks wings tail constantly, both when foraging and when perched.
Breeding. Nesting recorded in Jan–Feb in Sudan, May in Ethiopia, Jan and Jun in Kenya; birds in breeding condition in May in Uganda and in Aug and Oct–Mar in coastal Tanzania. One nest reported as in "an acacia". No other information.
Movements. No information.
Status and Conservation. Not globally threatened. Common to locally abundant. Across much of its range inhabits dry scrub, a habitat under little threat. Well represented in protected areas, including Kidepo Valley National Park, in Uganda, and Meru and Tsavo National Parks, in Kenya.
Bibliography. Ash & Miskell (1983, 1998), Britton (1972, 1980), Cave & MacDonald (1955), Cordeiro *et al.* (1995), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Hall & Moreau (1970), Jackson & Sclater (1938), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960), Mlingwa (1993), Nikolaus (1987, 1989), Stevenson & Fanshawe (2002), Turner & Zimmerman (1979), Urban & Brown (1971), Wilson & Wilson (1994), Wood (1989), Zimmerman *et al.* (1996).

71. **Pale Olive Greenbul**

Phyllastrephus fulviventris

French: Bulbul à ventre roux **German**: Angolabülbül **Spanish**: Bulbul Ventrirrufo

Taxonomy. *Phyllostrephus* [*sic*] *fulviventris* Cabanis, 1876, Chinchoxo, Loango Coast, Cabinda, Angola.
Forms a superspecies with *P. cerviniventris*. Monotypic.
Distribution. Extreme W DRCongo and NW & W Angola (Cabinda, and from Uíge and Cuanza Norte S to W Huíla and N Namibe).



Descriptive notes. c. 19 cm; male 32–38 g, female 27–30 g. Undistinguished-looking greenbul. Head is olive-grey, palest on forehead, lores pale, conspicuous white broken eyering merging with area of pale feathering above and behind eye; ear-coverts light olive-brown with whitish streaking; upperparts slightly paler than head, brown-tinged olive, uppertail-coverts and tail rufous; wings olive brown; throat creamy white; underparts pale yellow-brown, washed more olive-brown on breast and, especially, lower flanks, undertail-coverts pale yellowish-tawny; iris light brown, reddish-brown or dark brown; upper mandible blackish, lower mandible whitish-horn, pinkish-grey or grey, cutting edges pale, tip darker; legs pale purplish, flesh, bluish-grey or greenish-grey. Distinguished from similar *P. cabanisi* by being less green both above and below. Sexes alike, female on average smaller than male. Juvenile is as adult, but head concolorous with upperparts, more ginger on tail and uppertail-coverts, tail feathers more pointed, brighter yellow below, including throat. Voice. Burry, nasal chattering; alarm call said to be loud, sharp "tsik-tschirr-tschirr".
Habitat. Gallery forest, riparian thicket in dry *Croton* woodland, forest patches in savanna, secondary forest patches and coffee forest.
Food and Feeding. Little information; eats insects, including orthopterans. Forages mostly at low levels, including on ground, where searches in dead leaves; also recorded higher, including into canopy.
Breeding. Birds in breeding condition recorded in Aug–Sept. No other information.
Movements. No information.
Status and Conservation. Not globally threatened. Poorly known; considered not uncommon overall, but its status is unclear. Reports that it occurs in coastal SW Gabon are unconfirmed. Known to to present in Quiçama National Park, in Angola, but not recorded in other protected areas. Despite its relatively small range, this species' habitat preferences and apparent ability to adapt to secondary habitats suggest that it is unlikely to become threatened in the near future.
Bibliography. Borrow & Demey (2001), Chapin (1953), Dean (2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Hall & Moreau (1970), Keith *et al.* (1992), Lippens & Wille (1976), Mackworth-Praed & Grant (1960, 1963, 1973), Sargeant (1993).

72. **Grey-olive Greenbul**

Phyllastrephus cerviniventris

French: Bulbul vert-olive **German**: Fahlbauchbülbül **Spanish**: Bulbul Verdioliva

Taxonomy. *Phyllostrophus* [*sic*] *cerviniventris* Shelley, 1894, Zomba and Tschiromo, Malawi.
Forms a superspecies with *P. fulviventris*. Birds from SE DRCongo described as race *schoutedeni* on basis of darker and greyer underparts and less rufous tail feathers, but considered not satisfactorily distinguishable. Monotypic.
Distribution. Scattered localities across C & S Kenya, N & E Tanzania, extreme SE DRCongo, N & C Zambia, extreme E Angola, much of Malawi and parts of N Mozambique.

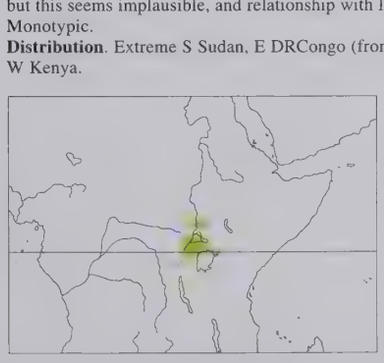
Descriptive notes. c. 18 cm; male 28·5–33 g, female 23·5 g. Medium-sized greenbul with striking orange or yellow eyes and pale legs. Lores are pale grey, side of face and ear-coverts brownish olive-grey with some indistinct paler streaking; indistinct pale broken eyering, darker line on lores and extending behind eye on some individuals; top of head and upperparts olive-grey, tinged brown, paler on lower back and rump; uppertail-coverts and tail rufous; wings olive-brown; throat pale whitish-buff, breast brownish olive-grey, flanks washed tawny, belly creamy buff, undertail-coverts pale tawny; iris orange, orange-yellow, golden-brown, salmon-pink or yellow, red rim; upper mandible dark horn, horn-grey, brownish or pinkish, lower mandible pale horn or whitish, pale cutting edges; legs pinkish-flesh, greyish-white or brownish-white. Distinguished from *P. strepitans* and *P. terrestris* by eye and leg colours; from *P. cabanisi* and *P. fischeri* by smaller size, duller throat, pale legs. Sexes alike; female on average smaller than male, possibly also with eye paler and lacking darker (red or reddish) outer ring of male. Juvenile is browner, less olive, above, secondary coverts edged tawny; eye pale grey, becoming greenish-grey. Voice. Calls include rasping, nasal "yekk-yekk-yekk", "ke-wek, wek wek wark" or continuous "zer-zer-zer-zer", a repeated "cherkiyeck" and a rapid "chewki-chiki-chew-chew".
Habitat. Riparian thicket, gallery forest, groundwater forest, bamboo thicket and moist evergreen forest; from 400 m to 1900 m.
Food and Feeding. Arthropods, including beetles (Coleoptera) and grasshoppers (Orthoptera); also some fruit. Occurs in pairs or small groups; has been recorded in mixed flocks with *P. strepitans*. Shy and unobtrusive. Forages in low tangles of dense vegetation, up to 4 m; gleans from leaves and bark, particularly of fallen logs, from the ground and, occasionally, in aerial sallies. Flicks wings and tail.
Breeding. Nesting recorded in Dec in Kenya, Sept–Nov and Apr (and in breeding condition in Oct) in Zambia, and Apr–May, Aug and Oct–Nov in Malawi; birds in breeding condition and juvenile in Apr in Mozambique. Nest an untidy, fairly deep cup, made of fine rootlets, dead leaves and moss, lined with rootlets, external diameter 10 cm, external depth 5·5 cm. Clutch 2 eggs; no information available on incubation and nestling periods; fledged young out of nest fed by both parents.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally scarce; may be locally fairly common. Known to occur in a number of protected areas.
Bibliography. Benson & Benson (1977), Benson *et al.* (1971), Britton (1972, 1980), Brooks *et al.* (1998), Chapin (1953), Cordeiro *et al.* (1995), Dean (2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett *et al.* (2004), Dowsett-Lemaire & Dowsett (2004), Hall & Moreau (1970), Jackson & Sclater (1938), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1960, 1963, 1973), Mallalieu (2001), Nalianya (2000), Stevenson & Fanshawe (2002), Turner & Zimmerman (1979), Vincent (1935a), Zimmerman *et al.* (1996).

73. **Baumann's Greenbul**

Phyllastrephus baumanni

French: Bulbul de Baumann **German**: Baumannbülbül **Spanish**: Bulbul de Baumann
Other common names: Baumann's Olive Greenbul

Taxonomy. *Phyllostrephus* [*sic*] *baumanni* Reichenow, 1895, Misahohé, Togo.
Has been thought possibly to form a superspecies with *P. hypochloris*, and sometimes considered conspecific, but morphological and vocal differences suggest that they are better treated as distinct species. Also, both sometimes considered to form a superspecies with *P. poensis* and *P. lorenzi*, but this seems implausible, and relationship with latter, at least, of these two does not seem close. Monotypic.
Distribution. NW Sierra Leone and SE Guinea E, apparently discontinuously, to SE Nigeria.



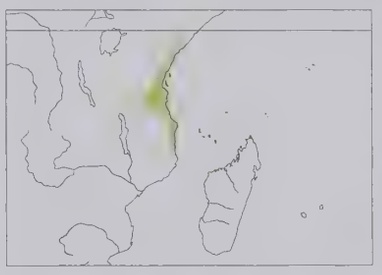
Descriptive notes. c. 18 cm; male 27·5–33 g, female 23·5–26·5 g. Plain bulbul with stout bill, few distinguishing features. Side of head is grey-brown with narrow pale shaft streaking, weakly contrasting indistinct darkish eyestripe from lores to rear of ear-coverts; top of head and upperparts dark olive-brown, rump, uppertail-coverts and tail rather more rusty brown (at most, only weakly contrasting); entirely pale olive-grey below, sometimes washed brownish on breast; iris dark brown, yellow-brown or reddish; bill dark brown above, greyish-horn below, pale cutting edges; legs greyish. Distinguished from *P. albigularis* by brown (not grey) head, olive-brown (not olive-green) upperparts, no contrasting white throat, no yellow tones below. Sexes alike, female on average somewhat smaller than male. Juvenile undescribed. Voice. Calls include series of "week" or "wik" notes, some loud, others fainter, and scolding "cherrr" note. Songs consists of 2–4 slightly nasal, rising notes, "whu whee wheew", followed by some harsh "wik" or "chewik" notes.
Habitat. Habitat preferences appear to be narrow; apparently tied to forest–savanna ecotone across much of its range, entering more deeply into lowland rainforest–secondary grassland mosaic only in far W. Mid-altitude forest and associated clearings and farmbush at 500–1100 m, often on hill and mountain slopes both within and beyond limits of lowland forest zone; also at lower altitudes, down to sea-level, in gallery forest and thicket, including in particular exotic *Lantana* and *Chromolaena*, on fringes of forest zone. Despite reports in the literature, no evidence that it occurs in lowland rainforest.
Food and Feeding. No information on diet; likely to be essentially insectivorous. Usually found in pairs or in small groups of 3–6 individuals; joins mixed-species feeding flocks. Very skulking and shy; forages mainly at or near ground level, occasionally up to 12–15 m. Depresses tail and flicks wings; raises crown feathers when agitated.
Breeding. No information.
Movements. No information; likely resident.
Status and Conservation. Not globally threatened. Data-deficient. Very poorly known; apparently rare, or rarely reported, throughout its wide range. Situation confused by published statements based on incorrect field identification. Known from relatively few localities; given its habitat requirements, however, likely to be more common and widespread than records suggest. Often overlooked or misidentified owing to its skulking behaviour, lack of obvious field characters, and frequent occurrence in degraded habitats. Occurs in some protected areas, including Mont Sangbé National Park, in Ivory Coast, and Bia and Digya National Parks, in Ghana. It is known from the Liberian section of Mt Nimba, and its presence in the newly created Nimba Nature Reserve is likely; expected to occur also in the protected parts of the mountain in Guinea and Ivory Coast. Occurs in Tingi Hills Non-hunting Forest Reserve, in Sierra Leone, Misahöhe Forest Reserve, in Togo, and IITA Forest Reserve, Ibadan, in Nigeria; has recently been found in Pic de Fon and Mont Béro Forest Reserves, in Guinea.
Bibliography. Allen (1930), Bannerman (1921, 1923, 1932, 1936, 1953), Bannerman & Lowe (1923), Bates & Bannerman (1931), Borrow & Demey (2001), Britton (1972), Butchart & Stattersfield (2004), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Demey (2001, 2002), Demey & Rainey (2004), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood (1977), Elgood & Sibley (1964), Elgood *et al.* (1994), Fishpool (1999, 2000), Fishpool *et al.* (1994b), Gatter (1997), Grimes (1987), Hall & Moreau (1970), Karr (1976), Keith *et al.* (1992), Lowe (1937), Mackworth-Praed & Grant (1973), Marchant (1953), Rand (1951), de Roo (1970), de Roo, de Vree & van der Straeten (1972), de Roo, de Vree & Verheyen (1969), Serle (1950a, 1957), Thiollay (1985).

74. Toro Olive Greenbul

Phyllastrephus hypochloris

French: Bulbul du Toro **German**: Torobülbül **Spanish**: Bulbul de Toro

Taxonomy. *Stelgidillas hypochloris* Jackson, 1906, Kibirau, Toro, Uganda.
Has been thought possibly to form a superspecies with *P. baumanni*, and sometimes considered conspecific, but morphological and vocal differences suggest that they are better treated as distinct species. Further, both sometimes considered to form a superspecies with *P. poensis* and *P. lorenzi*, but this seems implausible, and relationship with latter, at least, of these two does not seem close. Monotypic.
Distribution. Extreme S Sudan, E DRCongo (from Beni area S to Itombwe), W & S Uganda and W Kenya.



Descriptive notes. c. 17 cm; male 19–30 g, female 17–24 g. Smallish sombre greenbul with few distinguishing features. Entire head, including lores and ear-coverts, is brownish olive-green, appearing flecked (narrow dark fringes), ear-coverts with little streaking, indistinct pale broken eyering; upperparts olive-green, uppertail-coverts and tail dull rufous; wing feathers olive brown; throat pale grey, washed yellow, breast and flanks pale olive-green or yellowish-olive with faint greenish-yellow streaking, belly pale creamy yellow, undertail-coverts dull olive; iris brownish-orange, female rust-brown (Kenya); bill black, pale cutting edges and underside of lower mandible, yellowish gape; legs greenish-grey or bluish-grey. Distinguished from *P. cabanisi* by dark eye, duller plumage above and below, more uniformly olive on breast, pale throat less contrasting. Sexes alike, female on average smaller than male. Juvenile has head and underparts paler, light rufous undertail-coverts, bill dark brown. Voice. Song begins with several emphatic, raspy "whee-oo whéé" notes, usually followed by loud, scolding, descending "shree-shree-shree-shree".
Habitat. Evergreen and semi-deciduous forest. Usually in dense undergrowth and scrub at forest edge, beside rivers, and around clearings and adjacent farmbush, rather than deep within forest. Lowlands and middle altitudes, up to 1440 m in DRCongo, to 1600 m in Sudan, and to 2400 m in Uganda.
Food and Feeding. Largely insectivorous, but also some fruit. Found in pairs or in small (family?) groups; occasionally joins mixed-species flocks. Extremely skulking, forages in dense undergrowth, on low branches, tangles of dead leaves, fallen wood, creepers, etc.; mainly low down, occasionally ascending to middle levels. Wags tail slowly up and down, flicks wings.
Breeding. Birds in breeding condition in May in Sudan and in Dec–Mar in DRCongo (Itombe); pair seen while nest-building in creeper-clad tree. No other information.
Movements. No information; likely resident.
Status and Conservation. Not globally threatened. Locally common, but generally considered to be rare; probably under-recorded owing to its skulking behaviour and poorly known vocalizations. Known from several protected areas, including Virunga National Park, in DRCongo, and Bwindi-Impenetrable Forest, Kibale Forest, Semliki and Mount Elgon National Parks, in Uganda, Imatong Mountains Forest Reserve, in Sudan, and Kakamega Nature Reserve, in Kenya.
Bibliography. Bennun (1994), Britton (1972, 1980), Byaruhanga *et al.* (2001), Carswell (1986), Cave & MacDonald (1955), Chapin (1953), Dehn & Christiansen (2001), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Friedmann & Williams (1969, 1971), Hall & Moreau (1970), Jackson & Sclater (1938), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1960, 1973), Mann (1985), Nikolaus (1987, 1989), Prigogine (1971, 1978, 1980b, 1984), Schouteden (1957), Stevenson & Fanshawe (2002), Turner & Zimmerman (1979), Zimmerman (1972), Zimmerman *et al.* (1996).

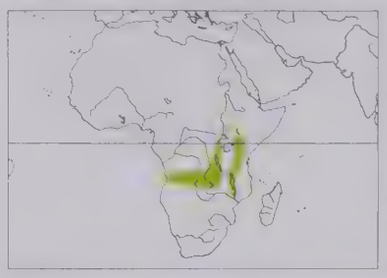
75. Fischer's Greenbul

Phyllastrephus fischeri

French: Bulbul de Fischer **German**: Fischerbülbül **Spanish**: Bulbul de Fischer

Taxonomy. *Criniger Fischeri* Reichenow, 1879, Muniuni, near mouth of Tana River, Kenya.
Forms a superspecies with *P. cabanisi*; has in the past been treated as conspecific, but differs in morphology (plumage, eye colour, bill structure) and voice, and the two recently found to occur together in Tanzania (parts of the Udzungwas). Has also been suggested that both form a superspecies with *Pyrrhurus scandens* (which sometimes included in present genus), but relationship seems remote. Biometric data for present species indicate a N–S cline of increasing size and weight. Monotypic.
Distribution. Extreme S Somalia (lower R Jubba), coastal Kenya (extending inland along lower R Tana and to Rabai and Shimba), E Tanzania (coastal region, inland to E Usambaras, E Ulugurus and Udzungwas) and NE Mozambique.

Descriptive notes. 17–18 cm; male 29–39 g, female 22–33 g. A distinctive white-throated, pale-eyed greenbul. Lores and ear-coverts are light olive-brown, some light streaking on ear-coverts, inconspicuous narrow white broken eyering; top of head and upperparts brownish-olive, rump, uppertail-coverts and tail dull rufous; wings greenish-brown; throat white, contrasting with greyish or brownish-olive breast and flanks, lower breast with some creamy-yellow streaks, belly creamy white to yellowish, undertail-coverts pale brown; iris white, cream, yellowish or tan; bill black or brownish-black, paler cutting edges; legs grey, tinged bluish or flesh. Distinguished from *P. cabanisi* by eye colour, white (not creamy) throat, also by voice; from *P. terrestris* and *P. strepitans* by pale eye, more olive coloration. Sexes alike, female on average smaller than male and with bill shorter and less fine. Juvenile resembles adult, but upperparts, breast and flanks darker, belly more yellow, eye grey. Voice. Calls include harsh scolding "churr" notes and explosive "pidi-tit"; contact call "prurrit prurrit"; other vocalizations include dry chattering "cherrrrh-cherrrh-cherrrh", sharper "chicck-chiccck-chiccck" and repeated rapid descending "chweeeeeeeeoh, chreeeeeeeeoh". The "churr" often quickens into distinctive phrase of 4–5 notes in which first note longest, loudest and highest, following notes on descending scale, "wréé-ga-ga-ga-ga", often answered by a neighbour.
Habitat. Lowland evergreen forest (including small patches is savanna), dense woodland and coastal thicket; mainly below 300 m, but in Tanzania reaching 750 m in Usambaras and Udzungwas and 850 m in Ulugurus.
Food and Feeding. Arthropods. Found in pairs or in small groups of 3–7 individuals; sometimes joins mixed flocks, and recently found in parts of Udzungwa Mts (Tanzania) in mixed-species flocks with *P. cabanisi*, but more often in single-species flocks. Unobtrusive and shy. Forages at low levels in dense tangles and on the ground; gleans from vegetation and by turning over leaf litter. Flicks tail and wings.
Breeding. Birds in breeding condition in Apr and Dec in Kenya, and in Jan–May and Oct–Nov (from beginning of short rains until end of long rains) in Tanzania. No other information.
Movements. No information.
Status and Conservation. Not globally threatened. Common to abundant over much of its range. No recent records from Somalia, possibly now extinct. No recent information from N Mozambique. Protected in Arabuko-Sokoke and Shimba Hills Forest Reserves, in Kenya; in Tanzania, occurs in the Selous Game Reserve as well as numerous forest reserves.
Bibliography. Ash & Miskell (1983, 1998), Britton (1972, 1980), Brown & Britton (1980), Dowsett (1972), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Hall & Moreau (1970), Jackson & Sclater (1938), Jensen & Brøgger-Jensen (1992), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960), Mlingwa (1996a), Stevenson & Fanshawe (2002), Svendsen & Hansen (1995), Turner & Zimmerman (1979), Zimmerman *et al.* (1996).



76. Cabanis's Greenbul

Phyllastrephus cabanisi

French: Bulbul de Cabanis **German**: Cabanisbülbül **Spanish**: Bulbul de Cabanis
Other common names: Kenya Highlands/Olive Mountain/Shelley's/Placid Greenbul (*placidus*)

Taxonomy. *Criniger cabanisi* Sharpe, 1882, Angola.
Forms a superspecies with *P. fischeri*; has in the past been treated as conspecific, but differs in morphology (plumage, eye colour, bill structure) and voice, and the two recently found to occur together in Tanzania (parts of the Udzungwas). Has also been suggested that both form a superspecies with *Pyrrhurus scandens* (which sometimes included in present genus), but relationship seems remote. Race *placidus* sometimes treated as a separate species on grounds of differences in size, coloration and habitat; studies have shown, however, that its vocalizations are very similar to those of nominate (in Malawi, reacts strongly to playback of nominate from Zambia). Additional Kenyan races *nandensis* (from N Nandi Forest) and *ngurumanensis* (Nguruman Range) treated as synonyms of *sucosus*, as differences in coloration on which descriptions were based are small and within range of variation of last-mentioned (although birds from Nandi rather greener above, with yellow margins of flight-feathers). Three subspecies recognized.

Subspecies and Distribution.
P. c. sucosus Reichenow, 1903 – extreme S Sudan, Kenya (W of Rift Valley), N, SW & E Uganda, E DRCongo (S to Mt Kabobo), Rwanda and NW Tanzania.
P. c. cabanisi (Sharpe, 1882) – NC Angola, SE DRCongo, N Zambia (except extreme NW) and W & SW Tanzania (S to Ufipa).
P. c. placidus (Shelley, 1889) – Kenya (E of Rift Valley), N, E & S Tanzania (W to Rungwe in S), extreme NE Zambia (Mafinga Mts), Malawi and NW Mozambique.

Descriptive notes. 16·5–19 cm; male 33–42 g, female 27–39 g (*cabanisi*), male 22–31 g, female 19–26 g (*sucosus*), male 21–32 g, female 19–31 g (*placidus*). A large long-tailed, slender-billed greenbul. Nominate race has lores and ear-coverts greyish olive-green, ear-coverts with faint paler streaking, narrow pale broken eyering, indistinct darker line in front of and behind eye; top of head and upperparts olive-green, uppertail-coverts and tail bright rufous, wings olive-green; throat and underparts yellowish, side of neck, breast and flanks washed greenish-olive, undertail-coverts pale brown; iris pale greyish-tan or pale grey; bill dusky horn, paler cutting edges; legs bright blue-grey. Distinguished from *P. fischeri* by yellower throat, from *P. cerviniventris* by bare-part colours, from both also by voice. Sexes alike, female on average smaller than male. Juvenile is bright olive above, pale yellow below, more olive on flanks and breast, bill black with yellow tip, eye pale olive-brown, feet greenish-grey. Race *sucosus* is smaller than nominate, brighter yellow below; *placidus* is also smaller, and browner overall, olive-brown above, throat creamy white, breast and flanks greyish-olive, bill horn-brown to horn-grey or yellowish-grey, paler base of lower mandible, eye brown, grey or dull yellowish-grey, legs slate-coloured. Voice. Race *placidus* contact call a harsh, low grating "churr" or "prrp-prrp"; song often in duet, one individual giving "churr", the other a whistled series of continuous double notes, "chirry, chorry, chirry, chorry" or "chrrrk, chrrrk, chrrrk-chrrrk, chwert-chwert", single bird may also sing unaccompanied; male call in pre-copulatory display a low "pruit-pruit-pri-pri, pri-pri-cho" or "prrp-prrp-perrup-perrup"; alarm a high-pitched "squii, squii" or " ziew-ziew-ziew". Voice of nominate very similar.
Habitat. Lowland, mid-altitude and montane primary and secondary forest of various types, gallery forest, riparian thicket, and dense woodland. Race *placidus* in Eastern Arc mountains of Tanzania commonest at c. 1500 m, ranges from 600 m in Usambaras (Tanzania) to 2000 m in Sudan, 2700 m in E Africa; nominate to 1700 m in Zambia; *sucosus* to 2400 m in Rwanda (Nyungwe).
Food and Feeding. Arthropods, including grasshoppers (Orthoptera), beetles (Coleoptera), mantids, caterpillars, ants (Hymenoptera), spiders (Araneae); also molluscs, some fruit. Found in pairs or in small groups of up to six individuals; sometimes joins mixed flocks, and recently found in parts of Udzungwa Mts (Tanzania) in mixed-species parties with *P. fischeri*, but seen more often in monospecific groups. Shy but inquisitive. Usually forages low down in dense undergrowth, on vertical to horizontal perches and on the ground, only occasionally moving higher than c. 2–4 m; rarely above 2 m where *P. flavostriatus* present, but in high forest where latter is absent regularly forages to 6–7 m above ground, sometimes to 16 m. Sometimes attends *Dorylus* ant swarms, but does not follow them into open understorey; remains within dense undergrowth. Gleans items from the ground among leaf litter, fallen wood, moss, also from leaves and from tree trunks, where it clings to bark while fluttering wings; also makes occasional short sallies. Flicks tail and wings, one wing at a time.
Breeding. Nesting recorded in Dec–Jan, Mar–May and Jul (thought to occur all year) in DRCongo, Dec–Mar in Sudan, Sept–Jan in Rwanda, and Dec–Aug (mainly in rains) in E Kenya and NE Tanzania; birds in breeding condition in Jun and Aug–Sept in Angola and Oct–Dec in Uganda; Oct–Feb (and juveniles also Sept) in Malawi, and Mar, Jul and Aug–Oct (breeding condition also Oct–Nov) in Zambia; double-brooded. Monogamous. Male in pre-copulatory display intermittently flicks wings and fans tail, erects crown feathers and fluffs throat and rump feathers, while hopping in circle through undergrowth while making low bubbling call. Nest, built by both sexes in 7–10 days, a shallow, elliptical cup of dead leaves, bark fibres, moss, tendrils, etc., bound together with cobwebs, outer layer with dead leaves and bark as camouflage, the whole appearing as bunch of trapped leaf debris, one measured 8·9 × 6·4 cm externally, 5·7 × 4·4 cm internally, outside depth 5·1 cm, inside depth 1·9 cm; placed 1·5–5 m above ground in vertical or lateral fork in dense undergrowth or low bush. Clutch 2 eggs, sometimes 3; incubation by both sexes, mainly female, period 11–12 days, longer in cold weather; nestling period 16–18 days; when surprised at nest, sitting bird may drop to ground and feign death, with wing half open, head limp, if approached will repeatedly stagger a few metres, trailing a wing and with spread tail, before collapsing.
Movements. Resident. One territory in Malawi was occupied by same group of birds for at least seven years, but some local altitudinal movement also recorded in that country.
Status and Conservation. Not globally threatened. Common and widespread. In Tanzania, density of 120 individuals/100 ha recorded Udzungwa Mts, and another study in Eastern Arc range reported a maximum density c. 25 individuals/km². Well represented in protected areas.

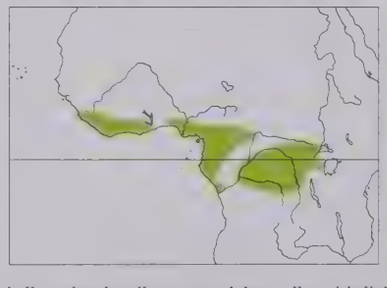
77. Cameroon Olive Greenbul

Phyllastrephus poensis

French: Bulbul olivâtre **German**: Bamendabülbül **Spanish**: Bulbul de Fernando Póo

Taxonomy. *Phyllostrophus* [*sic*] *poensis* Alexander, 1903, Bakaki, Bioko (Fernando Póo).
Affinities unclear. Has been suggested that it forms a superspecies with *P. baumanni*, *P. hypochloris* and *P. lorenzi*, but relationships with these species, especially the last-mentioned, seem remote. Monotypic.
Distribution. Highlands of SW Nigeria (Obudu and Mambilla Plateaux) and CW Cameroon (Tchabal Mbabo S to Mt Cameroon), and Bioko I.
Descriptive notes. c. 18 cm; male 28–32 g, female 24–25 g. Medium-sized, relatively long-tailed, plain-looking greenbul with relatively long and fine bill. Lores and side of face are grey with some



paler streaking on ear-coverts, indistinct pale grey broken eyering, faint darker line running through eye. Crown and upperparts, including wings, olive-brown, uppertail-coverts and tail dark rufous; throat dirty white, breast and flanks pale olive-brown, belly pale with some yellowish-white streaking, undertail-coverts pale rufous-brown; iris dark brown or chestnut; bill black, paler cutting edges; legs blue-grey. Sexes alike, female on average smaller than male. Juvenile has chestnut wash on upperparts, dull brownish band across breast, some rusty feathers on belly, flanks and undertail-coverts. Voice. Song a series of unmusical notes, "chewp chop chop chip chewp chip cher", and loud, scolding "kweep-kweep-kwerr-kweep-krr-kweep". Call a low "tchrr-tchrr-tchrr".
Habitat. Mid-altitude and montane forest between 750 m and 2200 m.
Food and Feeding. Insectivorous; some fruit also eaten. Occurs in pairs or small (family?) groups; regularly joins mixed-species parties e.g. at *Dorylus* ant swarms. Generally shy and unobtrusive. Forages in thick undershrubs and lianes, keeping to dense vegetation for most of the time, occasionally moving higher into upper levels. Gleans from leaves, tree trunks and branches. Depresses tail and flicks wings.
Breeding. Nesting recorded in Nov–Apr (mainly Nov–Jan, in dry season) in Cameroon, in Dec (and immature noted in Jun) in Nigeria, and Nov in Bioko. Nest an open cup of loose moss, leaf skeletons and leaves, intermediate layer of tendrils and lining of fibres, external diameter 8·5 cm, depth 9 cm, internal diameter 5·5 cm and cup depth 4 cm; c. 1·5 m above ground in low bush, attached by cobwebs to two or three moss-covered twigs, well camouflaged with moss. One nest had clutch of 2 eggs; no information on incubation and nestling periods.
Movements. No information.
Status and Conservation. Not globally threatened. Restricted-range species: present in Cameroon Mountains EBA. Fairly widespread and not uncommon within its small range; recently rediscovered to be not uncommon on Bioko, after many decades without any records. Occurs in a number of protected areas, including Basilé Peak National Park, in Bioko, Gashaka-Gumti Reserve, in Nigeria, and Banyang-Mbo Wildlife Sanctuary and Mount Oku Community Forest Reserve, in Cameroon; also present in other forest reserves in Cameroon.
Bibliography. Bannerman (1936, 1953), Borrow & Demey (2001), Bowden (2001), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1998b, 2001a, 2001b), Eisentraut (1963, 1973), Elgood *et al.* (1994), Fishpool & Evans (2001), Fotso (1996), Hall & Moreau (1970), Keith *et al.* (1992), Larison *et al.* (2000), Louette (1981), Mackworth-Praed & Grant (1973), Pérez del Val (1996), Serle (1954), Stattersfield *et al.* (1998), Stuart (1986).

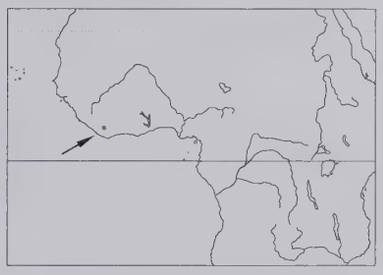
78. Icterine Greenbul

Phyllastrephus icterinus

French: Bulbul ictérin **German**: Zeisigbülbül **Spanish**: Bulbul Icterino
Other common names: Lesser Icterine Greenbul

Taxonomy. *Trichophorus icterinus* Bonaparte, 1850, Guinea.
Sibling species of *P. xavieri*, widely sympatric and very similar in appearance; difficulties in distinguishing the two have in the past led to some taxonomic confusion, and continue to hinder understanding of their respective distributions and ecologies. Relationship with *P. lorenzi* requires analysis; the two are almost entirely sympatric, closely similar in structure, overlap in dimensions, and appear also to intergrade in crown colour; latter is possibly a melanistic form of present species. Birds in E of range (Cameroon E to Uganda) described as race *tricolor*, on average somewhat greener above and duller yellow below, but not satisfactorily distinguishable as similarly coloured specimens occur elsewhere in species' range. Monotypic.
Distribution. W Sierra Leone and SE Guinea E to Ghana (one record Togo), and from SW Nigeria and Bioko E to SW Central African Republic and S to Gabon, W PRCongo, N Angola (Cabinda) and extreme W DRCongo (Mayombe); also across most of central DRCongo (S to S to Kasai and Kivu) and E to parts of W & S Uganda and extreme NW Tanzania.

Descriptive notes. 15–16 cm; 16·5–24·5 g, 15–22 g. Small, slender greenbul with conspicuous yellow throat. Lores and ear-coverts are pale olive-green with some yellowish streaking; inconspicuous yellowish eyering, obscure greenish-yellow line extending from in front of eye to a little way behind it (forming ill-defined supercilium); top of head and upperparts dull olive-green, uppertail-coverts and tail dull rufous; greater and median upperwing-coverts and flight-feathers dull olive-brown; throat sulphur-yellow, side of breast and flanks pale greenish or yellowish-olive, centre of breast yellow with olive wash, lower breast, belly and undertail-coverts sulphur-yellow; iris light brown or grey-brown; bill black or brownish-black above, grey or greenish-grey below, pale cutting edges and tip, yellow gape; legs bluish-grey or bluish-green. Distinguished from extremely similar *P. xavieri* by slightly smaller size and weaker bill, and in parts of range slightly brighter uppertail-coverts and tail; reliably separated in the field only by voice. Sexes alike, female on average smaller than male. Juvenile is greener above, breast and throat washed brownish. Voice. Song an unobtrusive, fast nasal chattering, slowing towards end, "chirrrup-chup-chup-chup-chup-chup"; alarm a nasal trill.
Habitat. Primary and old secondary evergreen and semi-deciduous forest, swamp-forest, forest–savanna mosaic; mostly in forest interior, infrequently coming to edge habitats. Mainly in lowlands, but recorded up to 900 m in Liberia, 1260 in Cameroon, 1250 m in Uganda and 1430 m in DRCongo.
Food and Feeding. Arthropods, including orthopterans, neuropterans, mantids, bugs (Hemiptera), beetles (Coleoptera), moths (Lepidoptera), caterpillars, termites (Isoptera), ants (Hymenoptera), spiders (Araneae); also some fruit and seeds. Usually occurs in small family groups of 3–5 individuals, thought to comprise a pair and previous brood (in Gabon, one bird ringed as a juvenile was recaptured 10 months later still with same two adults); groups of up to15 also recorded. Fairly shy. Forages in undergrowth and low bushes, mainly at 2–15 m (Liberia), 1–20 m (PRCongo). Gleans items from small branches, twigs, leaves, dense tangles, often flying after disturbed prey. Very



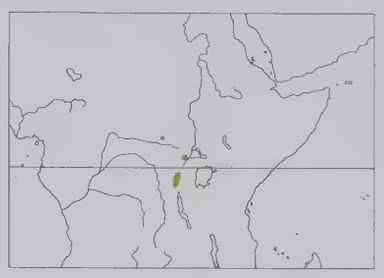
common component of mixed-species flocks, in which it may play role of leader, attracting other species to discovered food sources. Often, however, a follower, including of diurnal mammals, such as squirrels and small antelopes, capturing insects disturbed by the mammals' movements. Sometimes attends *Dorylus* ant swarms.
Breeding. Pair collecting nest material in Oct, fledglings Oct–Nov and independent juveniles Dec–Mar and May in Liberia; begging juveniles in May, Jul and Oct in Ivory Coast; in breeding condition in Sept in Ghana and Nov in Bioko; nest-building in Jan in Nigeria, and eggs in Jan, Jun and Sept and dependent fledglings Dec–Feb in Cameroon; nests with eggs Oct–Apr and newly fledged young Jun and Aug (probably breeds all year, with peak at end of rainy season and in short dry season) in Gabon; breeds all year in DRCongo; in breeding condition in Uganda in Jan–Feb. Monogamous; pair-bond long-lasting, both members of pair captured in same net in Gabon on several occasions, up to 61 months after ringing. Territorial, territory defended mostly by song, also by display with spread wings and tail, occasionally by fighting. Nest a small cup of dried leaves, a few twigs and rootlets, bound together by and sometimes also lined with hyphae of *Marasmius* fungus, outside camouflaged with dead leaves, external diameter 5–9 cm, depth 4–7 cm, internal depth 3–6 cm; suspended in hammock fashion, using cobwebs and *Marasmius*, 0·65–11 m above ground near end of horizontal branch of bush, shrub or liane, either in full view or hidden under large leaf. Clutch 2 eggs, rarely 1; incubation by female, when surprised she may fall to ground and perform distraction display, resembling running rodent, incubation period 14 days; chicks fed by both parents, leave nest after 12 days when still unable to fly, remain hidden in cover, where fed by parents; after 20–25 days, young join adults in mixed flocks. Of 38 nests watched in Gabon, 27 were preyed on, eight of remaining eleven each produced one young only (one egg infertile in four cases, one young disappeared in three).
Movements. Resident. Of 64 birds ringed in Gabon, 36 recaptured at least once at same site over period of up to 90 months; individuals observed up to 800 m from site of ringing.
Status and Conservation. Not globally threatened. Widespread, and generally common to abundant. Densities of up to 25–30 groups/km² in Gabon, 1 bird/5 ha in Nigeria, and 1 bird/ha in optimal habitat in N PRCongo. Occurs in many national parks across its large range, including those of Sapo, in Liberia, Taï Forest, in Ivory Coast, Kakum, in Ghana, Korup, in Cameroon, Nouabalé-Ndoki, in PRCongo, Salonga, in DRCongo, and Semliki, in Uganda.
Bibliography. Bannerman (1936, 1953), Borrow & Demey (2001), Britton (1972, 1980), Brosset (1971a), Brosset & Érard (1986), Chapin (1953), Cheke & Walsh (1996), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dean (2000), Demey & Fishpool (1994), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1991, 2001a), Elgood *et al.* (1994), Fishpool & Evans (2001), Fishpool *et al.* (1994b), Friedmann (1968), Gatter (1997), Germain & Cornet (1994), Grimes (1987), Hall & Moreau (1970), Jackson & Sclater (1938), Johnson, D.N. (1989), Keith *et al.* (1992), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1960, 1973), Pérez del Val (1996), Prigogine (1971, 1978, 1984), Rodewald *et al.* (1994), Sargeant (1993), Schouteden (1957), Stevenson & Fanshawe (2002), Thiollay (1985), Willis (1983).

79. **Liberian Greenbul**

Phyllastrephus leucolepis

French: Bulbul du Libéria **German**: Fleckflügelbülbül **Spanish**: Bulbul de Liberia
Other common names: Spot-winged Greenbul

Taxonomy. *Phyllastrephus leucolepis* Gatter, 1985, 20 km NW of Zwedru, near Cavalla River, Grand Gedeh County, Liberia.
Status unclear; relationship with *P. icterinus*, to which it is identical except for whitish spots on wings, requires investigation. Monotypic.
Distribution. Two forest patches 20 km NW of Zwedru, in E Liberia.



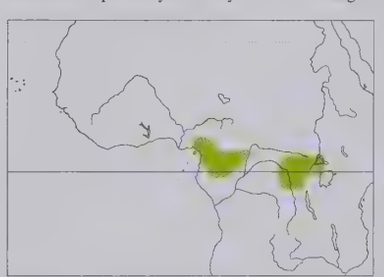
Descriptive notes. c. 16 cm. Small greenbul with yellow throat. Lores and ear-coverts are palish olive-green with some yellowish streaking, inconspicuous yellowish eyering; top of head and upperparts dull olive-green, uppertail-coverts and tail dull rufous; wings dull olive-brown, subterminal row of whitish spots (7–12 mm broad) on flight-feathers, another subterminal row of spots (3–4 mm broad) on greater wing-coverts, greater and median primary coverts and alula; throat and underparts sulphur-yellow, breast and flanks washed olive; eye colour not documented; bill black above, dark horn below, pale cutting edges and tip; legs pale grey. Distinguished from otherwise identical *P. icterinus* by spots on wing. Sexes probably similar. Juvenile undescribed. Voice. Unknown.
Habitat. Forest in transition zone between evergreen and semi-deciduous types.
Food and Feeding. Little information. Observed singly or in pairs; joins mixed-species flocks. Forages mainly between 4 m and 8 m, often in branches close to trunk; reported as flicking both wings, held partly open, simultaneously, this thought to act as a visual signal.
Breeding. No information.
Movements. No information; likely resident.
Status and Conservation. CRITICAL. Restricted-range species: present in Upper Guinea Forests EBA. Known only from the damaged type specimen (sex unknown), and from other individuals seen in same localities by the collector of the type. Forest in the type locality is unprotected and highly fragmented; logging is continuing, and the cleared land being settled for smallholder agriculture. Civil unrest in the area has undoubtedly added to the short-term exploitation of these resources.
Bibliography. Allport (1991), Borrow & Demey (2001), Butchart & Stattersfield (2004), Collar & Andrew (1988), Collar *et al.* (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Fishpool *et al.* (1994b), Gatter (1985, 1997), Keith *et al.* (1992), Morel & Chappuis (1992), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

80. **Sassi's Olive Greenbul**

Phyllastrephus lorenzi

French: Bulbul de Lorenz **German**: Lorenzbülbül **Spanish**: Bulbul de Lorenz
Other common names: Sassi's/Lorenz's Greenbul

Taxonomy. *Phyllastrephus lorenzi* Sassi, 1914, Moera, near Beni, eastern DRCongo.
Taxonomic status unclear; vocal and molecular data needed. Has been suggested that it forms a superspecies with *P. baumanni*, *P. hypochloris* and *P. poensis*, but affinities with these seem remote. Relationship with *P. icterinus* requires analysis; the two are almost entirely sympatric, closely similar in structure, overlap in dimensions, and appear also to intergrade in crown colour; possibly a melanistic form of that species. Monotypic.
Distribution. Scattered localities in NE & E DRCongo; one record from extreme W Uganda (Bwamba).



Descriptive notes. c. 15–16 cm; one female 19 g. A small greenbul with distinctive black cap. Lores and ear-coverts are dull olive, some faint darker streaking on ear-coverts, inconspicuous narrow olive eyering, obscure dirty yellowish line from in front of eye to a little way behind it (vague supercilium); forehead olive-brown, forecrown to nape variably mottled black and olive, blackest on crown, sometimes appearing as well-defined black cap, sometimes merely as less distinct darker area; upperparts dark dull olive-brown, uppertail-coverts slightly more rufous, tail dark reddish-brown; wings blackish-brown, outer margins of primaries light greenish-brown, bend of wing olive-yellow; throat olive-yellow, underparts dirty yellowish olive-green, paler olive-yellow in centre of belly, undertail-coverts brownish-yellow; two aberrant museum specimens with irregular warm brown patches on crown, mantle, back, wing-coverts, breast side and lower flanks; iris dark brown; bill blackish-brown, paler lower mandible, cutting edges and tip; legs greyish, greyish-brown or blackish. Distinguished from *P. icterinus* by darker overall coloration, black cap diagnostic. Sexes alike, female on average smaller than male. Juvenile said have blackish area on crown poorly developed. Voice. No information.
Habitat. Primary forest at c. 600–1580 m; record at 1820 m requires confirmation. Not recorded from secondary habitats.
Food and Feeding. Little information; likely to be mainly insectivorous. Occurs in small groups in lower and lower-middle strata; joins mixed-species flocks.
Breeding. Birds in breeding condition in Jan, Mar–May and Aug. No other information.
Movements. No information.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Eastern Zaïre Lowlands EBA. Poorly known. Recorded from Kibali-Ituri District (from Bondo Mabe and Irumu S to Beni, including Ituri and Semliki forests), with a single record just over the border in Uganda (at Bwamba); in South Kivu, one record from Hombo (W of Mt Kahuzi) and another from around Kamituga (Itombwe); also, a single record from Bambesa, in Uele District. Potentially threatened by clearance of habitat for shifting cultivation, and degradation through the removal of understorey trees to create cocoa plantations; situation exacerbated by this species' apparent inability to tolerate secondary habitats. Has been recorded from Kahuzi-Biéga National Park, Okapi Faunal Reserve and Mount Hoyo Reserve, but the degree to which its habitat can currently be considered protected is questionable.
Bibliography. Britton (1972, 1980), Butchart & Stattersfield (2004), Byaruhanga *et al.* (2001), Chapin (1953), Dowsett (1985a), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Friedmann & Williams (1968), Hall & Moreau (1970), Keith *et al.* (1992), Lippens & Wille (1976), Mackworth-Praed & Grant (1973), Plumptre (1997), Plumptre & Mutungire (1996), Prigogine (1971, 1978, 1980b, 1984, 1985), Schouteden (1957), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stevenson & Fanshawe (2002).

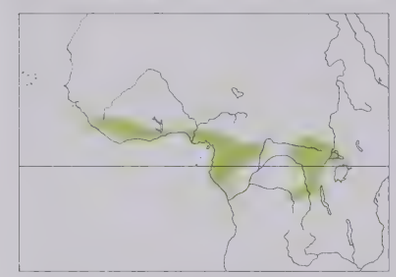
81. **Xavier's Greenbul**

Phyllastrephus xavieri

French: Bulbul de Xavier **German**: Xavierbülbül **Spanish**: Bulbul de Xavier
Other common names: Greater Icterine Greenbul

Taxonomy. *Xenocichla Xavieri* Oustalet, 1892, Bangui, on Ubangi River, Central African Republic.
Sibling species of *P. icterinus*, widely sympatric and very similar in appearance; difficulties in distinguishing the two have in the past led to some taxonomic confusion, and continue to hinder understanding of their respective distributions and ecologies. Birds from Cameroon (N & W of Mt Cameroon) described as race *serlei* on basis of paler and duller yellow underparts, with darker olive wash on breast, but these characters fall within range of variation of the species elsewhere. Monotypic.
Distribution. Extreme SE Nigeria and W Cameroon E to SW Central African Republic, S to C Gabon and NE PRCongo; also EC DRCongo E to W & S Uganda and extreme NW Tanzania. Distribution probably not fully resolved owing to confusion with *P. icterinus*.

Descriptive notes. 16–18 cm; male 23–31 g, female 16–22 g. Smallish greenbul with conspicuous yellow throat. Has lores and ear-coverts pale olive-green with some yellowish streaking, inconspicuous yellowish eyering, obscure greenish-yellow line extending from in front of eye to a little way behind it (ill-defined supercilium); top of head and upperparts dull olive-green, uppertail-coverts rufous sometimes with greenish wash, tail dull rufous; greater and median upperwing-coverts and flight-feathers dull olive-brown; throat sulphur-yellow, side of breast and flanks pale greenish or yellowish-olive, centre of breast yellow with olive wash, lower breast, belly and undertail-coverts sulphur-yellow; iris dark brown, light brown or pale grey; bill black or dark brown above, light grey or greenish-grey below, pale cutting edges and tip, yellow gape; legs bluish-grey, brown, pale mauve-brown or flesh. Distinguished from extremely similar *P. icterinus* by slightly larger size and heavier bill, and in parts of range slightly duller uppertail-coverts and tail; reliably separated in the field only by voice. Sexes alike, female on average smaller than male. Juvenile is greener above, paler below, more olive on breast. Voice. Short, nasal "kwah, kwah, kwah…kwahkwah" and more drawn-out, squeaky "kwèèèh" or "kèèh", uttered in shorter or longer series of either similar or combined notes, "kwah-kèèh".
Habitat. Primary and old secondary evergreen and semi-deciduous forest, and swamp-forest; occurs both in forest interior and, to lesser extent, in edge habitats. Mainly lowlands, but recorded to 900 in Cameroon, 1500 m in Uganda and 1470 m in DRCongo.



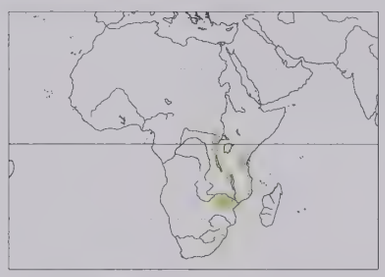
Food and Feeding. Arthropods, including orthopterans, beetles (Coleoptera), moths (Lepidoptera), caterpillars, mantids, spiders (Araneae); also some fruit and seeds. Usually found in pairs or in family groups of 4–6 individuals; regular member of mixed-species flocks, often with *P. icterinus*. Appears to forage at most levels, in Gabon reportedly mainly from 15 m up to canopy; elsewhere, said to be found more often in understorey. Gleans from leaves, tangles and similar sites; pursues disturbed prey in flight.
Breeding. Birds in breeding condition in Jan–Mar and Aug and dependent fledglings in Jan–Feb in Cameroon; nest thought to be of this species found in Feb in Gabon; in DRCongo, nesting recorded Nov–Jun in Itombwe, probably breeds throughout year at equator; in breeding condition Feb, Apr and Jun–Jul and juvenile in May in Uganda. Territorial. Nest a cup of dry leaves lined with rootlets, external diameter 8 cm, depth 5·5–6 cm, internal depth 3·5–4 cm, built 1–2·5 m above ground in fork of thin branch, or placed between two small branches, in bush in dense undergrowth. Clutch 2 eggs; no information on incubation and nestling periods.
Movements. Resident, so far as known. Ringed individual in Gabon retrapped at same site after 68 months.
Status and Conservation. Not globally threatened. Status obscured owing to confusion with the more widespread and common *P. icterinus*; considered locally common to uncommon. Occurs in many protected areas across its large range, including Korup National Park, in Cameroon, Nouabalé-Ndoki National Park, in PRCongo, Okapi Faunal Reserve, in DRCongo, and Semliki National Park, in Uganda.
Bibliography. Bannerman (1936, 1953), Borrow & Demey (2001), Bowden (2001), Britton (1972, 1980), Brosset & Érard (1986), Chapin (1953), Christy & Clarke (1994), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1991, 2001a), Fishpool & Evans (2001), Friedmann (1968), Germain & Cornet (1994), Hall & Moreau (1970), Keith *et al.* (1992), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1960, 1973), Manu & Demey (1999), Prigogine (1971, 1978, 1984), Rodewald *et al.* (1994), Sargeant (1993), Schouteden (1957), Smith *et al.* (1996), Stevenson & Fanshawe (2002).

82. White-throated Greenbul

Phyllastrephus albigularis

French: Bulbul à gorge blanche **German**: Schuppenstirnbülbül **Spanish**: Bulbul Gorgiblanco

Taxonomy. *Xenocichla albigularis* Sharpe, 1882, Fantee, Ghana.
Distinctive species of unclear affinities; not obviously closely related to any other member of genus. Two subspecies recognized.
Subspecies and Distribution.
P. a. albigularis (Sharpe, 1882) – SW Senegal, and Sierra Leone and SE Guinea E through C Nigeria to SW Central African Republic and S to S PRCongo; also NW, W & E DRCongo (Duma, lower R Congo at Kunungu, and E from Sankuru and Kasai), SE Central African Republic, extreme S Sudan, and NW, W & C Uganda.
P. a. viridiceps Rand, 1955 – NW Angola (Cuanza Norte, N Cuanza Sul).



Descriptive notes. c. 17 cm; male 24–31 g, female 17–28 g. Small pale-eyed greenbul with relatively long, dagger-like bill. Nominate race has head and neck olive-grey, darker feather fringes producing scaly appearance; lores and periorbital area grey (paler than crown), ear-coverts slightly darker grey-brown with some paler streaks and darker fringes (appearing scaly, like rest of head); upperparts, including wings, dark olive-green, uppertail-coverts and tail olive-rufous; throat white, breast and flanks olive-green to olive-grey, lower breast and belly pale yellow, deeper yellow on lower belly and yellow-olive on undertail-coverts; iris dirty white, pale grey or cream; bill black, dark blue-horn or dark grey, yellowish cutting edges and tip, lower mandible paler on underside; legs grey or bluish-flesh. Sexes alike, female on average smaller than male. Juvenile resembles adult, but with yellow gape, light brownish-grey eyes. Race *viridiceps* has crown washed green, upperparts on average greener than nominate, throat washed pale yellowish-buff, underparts on average yellower, eyes greyish-brown. Voice. A series of rapid, clear scolding notes, usually rising in pitch and then dying way, usually preceded by loud "turrr'. Contact calls include low, monotonous "prrp-prrp", "trr-trrp" or "prrchurrup".
Habitat. Primary and old secondary forest and gallery forest; in W of range at least, more common in drier, semi-deciduous forest than in wetter forest types. Favours edge habitats rather than forest interior. Lowlands, to 1000 m in Liberia and 1850 m in Uganda.
Food and Feeding. Arthropods, including orthopterans, neuropterans, bugs (Hemiptera), beetles (Coleoptera), moths and their caterpillars (Lepidoptera), ants (Hymenoptera), spiders (Araneae); also small gastropods, and some fruit. Occurs in pairs and small family groups; joins mixed-species parties, but at least equally likely to be found in small monospecific flocks. Unobtrusive and shy. Forages mostly very low down, but will move into middle and upper strata on occasion. Gleans food from leaves, stems and branches in dense vegetation tangles, particularly around edges of clearings, along rivers, and around treefalls and similar places. Flicks wings and tail while foraging.
Breeding. Nesting recorded in Mar–May in Uganda; juvenile seen in Jul in Gabon, where singing activity increases at beginning of rainy seasons and during short dry season, and breeding condition recorded in Dec; birds in breeding condition in Aug–Nov in Nigeria, Aug in Cameroon and DRCongo, May in Central African Republic and Feb in Angola. Territorial throughout year. Nest built in fork of branch or slung between two branches in low forest bush. Clutch 2 eggs; incubation by female only; no information on incubation and nestling periods.
Movements. Resident. Individuals ringed in Gabon retrapped at same site after 11 and 72 months.
Status and Conservation. Not globally threatened. Widespread, but distribution strangely patchy; assessed as common to abundant in some parts of its range, scarce and rare in others. Probably overlooked in some areas. Densities estimated at 10–12 pairs/km² in Gabon and 1 bird/10 ha in Nigeria. Known to occur in a number of national parks, such as those of Taï Forest, in Ivory Coast, Bia, in Ghana, Mbam-Djerem, in Cameroon, Minkébé, in Gabon, Nouabalé-Ndoki, in PRCongo, and Kibale Forest, in Uganda; occurs also in Okapi Faunal Reserve, in DRCongo.
Bibliography. 83. Yellow-streaked Greenbul

Phyllastrephus flavostriatus

French: Bulbul à stries jaunes **German**: Gelbstreifenbülbül **Spanish**: Bulbul Listado
Other common names: Yellow-streaked Bulbul, Yellow-striped Greenbul; Sharpe's/Malawi Greenbul (*alfredi*)

Taxonomy. *Andropadus flavostriatus* Sharpe, 1876, Macamac, Gauteng, South Africa.
Forms a superspecies with *P. poliocephalus*; has been considered conspecific by some authors, but is much smaller, differs significantly in plumage characters and has distinctive song. Has been suggested that brown-headed race *alfredi* merits treatment as full species, but no significant vocal differences from other races. Several poorly differentiated races merged: thus, *itombwensis* (E DRCongo) and *ruwenzori* (W Uganda) treated as synonyms of *olivaceogriseus*, and *dendrophilus* (E Zimbabwe), *distans* (E Eastern Cape, in South Africa) and *dryobates* (Mt Gorongosa, in Mozambique) synonymized with nominate. Eight subspecies recognized.
Subspecies and Distribution.
P. f. olivaceogriseus Reichenow, 1908 – R DRCongo (Ruwenzori Mts, Itombwe and Mt Kabobo), W & SW Uganda, W Rwanda and N Burundi.
P. f. graueri Neumann, 1908 – highlands W of L Albert, L Edward and L Kivu, in E DRCongo.
P. f. kungwensis Moreau, 1941 – Kungwe-Mahari Mts, in W Tanzania.
P. f. tenuirostris (Fischer & Reichenow, 1884) – SE Kenya and E Tanzania S to E Mozambique lowlands (N of R Zambezi).
P. f. uzungwensis Jensen & Stuart, 1982 – E escarpment of Udzungwa Mts, in Tanzania.
P. f. alfredi (Shelley, 1903) – SW Tanzania, NE Zambia and N Malawi.
P. f. vincenti C. H. B. Grant & Mackworth-Praed, 1940 – SE Malawi (E of R Shire) and adjacent N Mozambique.
P. f. flavostriatus (Sharpe, 1876) – S Mozambique lowlands (S of R Zambezi), E Zimbabwe, NE & E South Africa and NW Swaziland.

Descriptive notes. 18–20 cm; male 31–40 g, female 26–30 g, male 32–42 g and female 23–34 g (*olivaceogriseus*). Nominate race has top and side of head and neck brownish-grey, lores slightly paler, ill-defined blackish line immediately before eye and extending behind it, conspicuous, fairly wide whitish broken eyering, some indistinct paler and darker streaking on ear-coverts; upperparts, including wings and tail, olive-brown; throat white; underparts whitish, grey-brown wash on breast and flanks, lightly streaked pale yellow from lower breast to undertail-coverts; iris grey to blue-grey, bill black or dark brown, paler base of lower mandible, yellow cutting edges; legs light grey or lead-grey. Sexes alike, female on average smaller than male. Juvenile has breast tinged dusky olive, centre of belly pale yellow. Race *olivaceogriseus* has head and neck grey, is more olive-green above, wings bright greenish, underparts washed grey, amount of yellow on belly as nominate; *graueri* is greener on back, with rump and uppertail-coverts gingerish, wing-coverts and edges of flight-feathers greenish-rufous, underparts less grey, yellow streaking extending to breast and upper belly, lower belly wholly yellow; *kungwensis* resembles previous, but crown somewhat darker grey, belly and undertail-coverts paler yellow; *tenuirostris* differs from last in having wings brownish-olive, underparts pale yellow, flanks olive-green, undertail-coverts brownish-yellow; *vincenti* is duller below than previous, throat more dirty white, underparts more grey, yellow streaking narrow and dull; *uzungwensis* has belly wholly and conspicuously yellow; *alfredi* is distinctive, top of head and neck brown (not grey), upperparts olive-tinged brown, uppertail-coverts dark rust, tail reddish-brown with greenish edging, wing-coverts and edges of secondaries and inner primaries rufous-brown, underparts whitish, breast side brown, undertail-coverts light brown. Voice. Song in E Africa a series of loud, distinct, descending notes, somewhat increasing in tempo towards end, "tchwik tchwerk tchk tchee tchow tchow tchichick -tcherk tchikikik", or 4–5 whistled downslurred notes followed by 3–4 faster ones on same pitch, "chip cher cher choy chewy tu-tu-tu"; in S part of range, often a longer series of initial downslurred notes with no faster ones at end; song usually preceded by variety of trills and call notes. Contact call a nasal, twangy "tyer-tyer" or "chow".
Habitat. Lowland, mid-altitude and, especially, montane forest, riverine forest, thick bush, small forest patches, sometimes bamboo. Occurs from sea-level to 3000 m; in Eastern Arc mountains of Tanzania, most common at 1100–1500 m.
Food and Feeding. Arthropods, including grasshoppers (Orthoptera), beetles (Coleoptera), bugs (Hemiptera), caterpillars, spiders (Araneae); also small gastropods, and some fruit. Occurs typically in groups of 5–6 individuals, occasionally in pairs or alone; a frequent and conspicuous member of mixed-species parties, but may also occur in monospecific flocks. Forages at all levels, usually above 4 m in middle and upper strata, but also in undergrowth down to 1–2 m. Noisy and conspicuous. Gleans from leaves and bark, peers into holes, climbs up vertical lianes; often favours epiphyte-clad branches, which it works over methodically, probing into moss, ferns, bundles of dead leaves, bark crevices, etc. On horizontal branches, often peers alternately over one side and then the other as it works along, sometimes hanging off sideways or upside-down to reach prey. Often progresses by working steadily upwards from low within a tree, sometimes switching trees, but on reaching canopy flies to base of nearby tree and repeats process. Has distinctive habit of deliberately but rapidly raising and lowering one wing at a time (exposing yellow underwing-coverts), both when foraging, as when peering beneath a branch, and in agitation; also pumps tail slowly upwards and quickly down.
Breeding. Nesting recorded in Feb–Oct and juveniles in Jan in DRCongo; in Jul and Nov, and nest-building in Jan, in Uganda; in Aug and Oct–Jan (birds on coast in breeding condition Jan–Jun, Oct–Nov) in Tanzania; Aug–Jan in Zambia and Sept–Jan in Malawi; Sept and Nov (in breeding condition Jul, and nest-building in Jan) in Mozambique; Oct–Jan (peak Nov–Dec) in Zimbabwe and Oct–Mar in South Africa. Monogamous. Solitary nester, territorial. Nest a flimsy cup of dark rootlets, twigs, tendrils, dried leaves, bark fragments, hyphae of *Marasmius* fungus, bound together with cobwebs, lined with fine grass inflorescences and rootlets (e.g. of epiphytic fern *Microsorum*) or unlined, outside decorated with moss, underside usually encased and concealed by 2–3 large dead leaves; shape often asymmetrical (longer axis parallel with supporting twigs), external diameter 6–12 cm, depth 5–8 cm, internal diameter 4·5–6·5 cm, depth 2·5–4·5 cm; built 1–2 m above ground in dense vegetation, e.g. among fern fronds or in bunch of dead leaves or

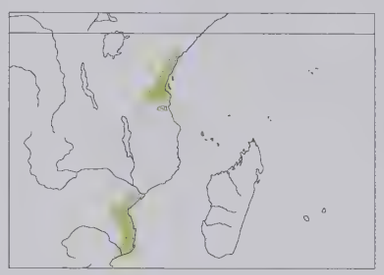
creepers, or hung from horizontal fork of small branch such that rim does not extend above supporting stems. Clutch 2 eggs, sometimes 3; incubation by female only; no information on incubation and nestling periods. Estimated mean annual mortality rates in Malawi 35% for males, 60% for females.
Movements. Largely sedentary; 14 ringed individuals in Malawi retrapped only 20–380 m from site of ringing. Some evidence of altitudinal movement in Malawi; also some wandering, as individuals occasionally appear at isolated forest patches 10 km from nearest regular habitat; one estimated to have travelled at least 32 km across woodland.
Status and Conservation. Not globally threatened. Race *alfredi*, sometimes treated as a separate species, is a restricted-range taxon: present in Tanzania-Malawi Mountains EBA. Common to locally abundant. No recent records from SE Kenya (race *tenuirostris*). Estimated density in N Malawi 3–4 pairs/10 ha; in Tanzania, 105 individuals/100 ha in Udzungwa Mts, and maximum density of c. 70 individuals/km² reported in another study in Eastern Arc mountains. Occurs in a number of national parks, including those of Ruwenzori, in Uganda, Volcans, in Rwanda, Virunga, in DRCongo, Udzungwa, in Tanzania, and Nyika, in Malawi; present also in numerous forest reserves and other protected areas.
Bibliography. Benson & Benson (1977), Benson *et al.* (1971), Britton (1972, 1980), Brown & Britton (1980), Chapin (1953), Clancey (1964, 1996), Dinesen (1997), Dowsett (1990), Dowsett & Dowsett-Lemaire (1980, 1993), Dowsett & Forbes-Watson (1993), Dowsett *et al.* (2004), Dowsett-Lemaire (1983, 1989), Dowsett-Lemaire & Dowsett (2004), Ginn *et al.* (1989), Hall & Moreau (1970), Harrison *et al.* (1997), Irwin (1981), Jackson & Sclater (1938), Jensen & Brøgger-Jensen (1992), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louw (2005c), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993), Mlingwa (1996a), Moyer (1993), Romdal (2001), Sclater & Moreau (1932), Stattersfield *et al.* (1998), Stevenson & Fanshawe (2002), Tarboton (2001), Turner & Zimmerman (1979), Vernon *et al.* (1990), Zimmerman *et al.* (1996).

84. Grey-headed Greenbul

Phyllastrephus poliocephalus

French: Bulbul à ventre jaune **German**: Goldbauchbülbül **Spanish**: Bulbul Ventriamarillo
Other common names: Yellow-bellied Greenbul

Taxonomy. *Xenocichla poliocephala* Reichenow, 1892, Buea, 1200 m, Mount Cameroon, Cameroon.
Forms a superspecies with *P. flavostriatus*; has been considered conspecific by some authors, but is much larger, differs significantly in plumage characters, and lacks the distinctive song of that species. Monotypic.
Distribution. Extreme SE Nigeria (Obudu Plateau) and W Cameroon (Banyang Mbo and Mt Manengouba S to Mt Cameroon).



Descriptive notes. 20–23 cm; male c. 54·5–65 g, female c. 37·8 g. Large, distinctive montane greenbul. Top of head and neck are grey, side of face grey, indistinct pale loral line, narrow inconspicuous white eyering; mantle grey-green, becoming green on back and scapulars, brighter green on rump and upper-tail-coverts; upperwing-coverts olive-brown, flight-feathers yellow-olive; tail olive-brown, edged green, with narrow yellow tips of all except central feather pair; throat white, underparts, including undertail-coverts, bright yellow; iris dark brown, grey-brown or grey; upper mandible grey or blackish, lower mandible paler, yellowish, pale horn cutting edges and tip; legs grey. Sexes alike, female on average considerably smaller than male. Juvenile undescribed. Voice. Calls include loud, sharp, repeated "churp" or "tyow", often repeated, and fast "churp-p-p" or "chrititit", sometimes combined as "ti-ti-ti-ti-tyow"; similar to calls of *P. flavostriatus*.
Habitat. Mature mid-altitude forest between 500 m and 1800 m, rarely to 2000 m; on Mt Kupé (Cameroon) most numerous at 1200–1800 m. Less frequent in secondary forest.
Food and Feeding. Insectivorous. Usually occurs in small, noisy, boisterous, mobile groups, more rarely singly; frequent and conspicuous member of mixed-species parties. Forages mainly in middle strata and canopy, but periodically descending to 3–4 m. Gleans from mossy trunks, epiphytes, lianes, loose bark, etc.; hops rapidly along horizontal moss-clad, branches, peering first over one side and then over the other, pausing periodically to probe. Pumps tail and flicks wings frequently.
Breeding. In Cameroon, nest with young (Mt Kupé, at 2000 m) in Apr, dependent juvenile in Mar and immatures Jan–Feb, and birds in breeding condition in Nov and Jan–Mar. No other information.
Movements. No information.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Cameroon Mountains EBA. Common in suitable habitat within its small range. Earlier reports of its occurrence in the Bamenda Highlands (Cameroon) are incorrect. Potential threats include unsustainable exploitation of timber, uncontrolled burning, and clearance of habitat for agriculture. Occurs in the Banyang-Mbo Wildlife Sanctuary and Rumpi Hills Forest Reserve, both in Cameroon. The other Cameroon localities where it is known to be present, Mt Manengouba, Mt Nlonako, Bakossi Mountains, Mt Kupé and Mt Cameroon, are not formally protected in any way, nor is the Obudu Plateau, the species' single Nigerian site.
Bibliography. Bannerman (1936, 1953), Borrow & Demey (2001), Bowden (2001), Butchart & Stattersfield (2004), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1998b, 1999, 2000), Eisentraut (1963, 1973), Elgood *et al.* (1994), Fishpool & Evans (2001), Hall & Moreau (1970), Keith *et al.* (1992), Louette (1981), Mackworth-Praed & Grant (1973), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stuart (1986).

85. Tiny Greenbul

Phyllastrephus debilis

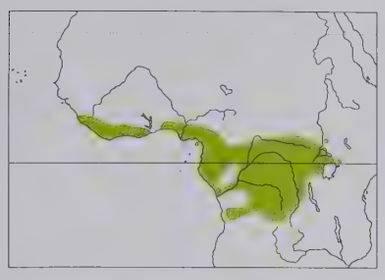
French: Bulbul minute **German**: Schlankbülbül **Spanish**: Bulbul Chico
Other common names: Slender Bulbul, Smaller Yellow-throated/Miniature Greenbul; Usambara/Green-headed Greenbul (*albigula*)

Taxonomy. *Xenocichla debilis* W. L. Sclater, 1899, north of Inhambane, south Mozambique.
No close relatives; conspicuously smaller than any of its congeners. Race *albigula* considered by some to be possibly an incipient species, but intergrades with other races reported. Three subspecies recognized.
Subspecies and Distribution.
P. d. rabai Hartert & van Someren, 1921 – C & S coastal Kenya and NE coastal Tanzania (S to R Rufiji).
P. d. albigula (Grote, 1919) – Usambara Mts, Nguru Mts and Nguu Mts, in E Tanzania.
P. d. debilis (W. L. Sclater, 1899) – SE Tanzania, S Mozambique and extreme E Zimbabwe (Haroni-Rusitu).

Descriptive notes. 13–14 cm; male 13·5–17 g, female 12·5–15 g. Smallest African bulbul and smallest member of genus, differs from others in lacking nail on upper mandible; sharply defined grey head and pale eyes. Nominate race has top of head and neck grey, lightly washed olive; lores and ear-coverts grey, slightly paler than crown, some indistinct paler streaking; upperparts dull olive-green, tail slightly browner but not contrasting, wings olive-green; throat white, breast and belly pale grey-white, washed greyer on flanks and across breast, some pale yellow streaking; lower belly and undertail-coverts light yellow-olive; iris white or creamy to pale yellow or golden; bill grey or blue-grey, paler lower mandible and cutting edges; legs black or grey. Sexes alike, female on average smaller than male. Juvenile has top of head greener, similar to back. Race *albigula* differs from nominate in having strong olive-green wash on crown and nape, upperparts darker, throat greyish, underparts darker and greyer with little yellow, upper mandible blackish, eye yellow or yellowish-orange; *rabai* has head and neck grey without greenish tones, upperparts bright olive-green, resembles nominate below but yellow tones brighter, belly yellowish-white, undertail-coverts pale greenish-yellow, bill variable, sometimes greyish-horn or brownish, eye sometimes red-brown or dark grey-brown (possibly age-related). Voice. Alarm or contact call of race *albigula* a gurgling "chrrrrrr", of *rabai* a rasping "chicidididididi", rising in pitch, also low "churr" and nasal "nnyeh nnyeh"; *albigula* has soft but explosive "tut" as contact when foraging in group. Song a series of short "chit" or "tut" notes mixed with lower, more nasal "nya" or "dya" sounds, e.g. "chitchitchit, chit-nya-nya-nya".
Habitat. Lowland evergreen forest, forest–woodland mosaic, thick coastal scrub, gallery forest; sometimes woodland, including miombo. Appears to tolerate disturbed forest in parts of range, but recorded only in intact forest in others. Sea-level to 1550 m; race *albigula* above 300 m in E Tanzania mountains.
Food and Feeding. Insectivorous. Usually seen in pairs or in small parties, sometimes singly; often joins mixed-species parties. Forages mostly in lower and middle strata (mostly below 4 m), but does sometimes ascend to canopy; generally keeps to dense undergrowth and lianes, and prefers thin branches and creepers; group-members constantly call to each other. Gleans insects from leaves with agility, reminiscent more of a warbler (Sylviidae) than of a bulbul; flicks wings.
Breeding. Nesting recorded in Dec and May; birds in breeding condition in Oct–May in coastal Tanzania and Oct–Jan in Zimbabwe. Monogamous. Solitary nester, territorial. Nest a small neat cup of dark fibres, tendrils, black hyphae of *Marasmius* fungus, ferns, lichens and dry leaves, bound together with cobwebs, lined with fine plant stems; often asymmetrical (longer axis parallel with supporting twigs), external diameter 6–7 cm, depth 4–6 cm, internal diameter 3·5–5 cm, cup depth 2·2 cm; usually c. 1 m (range 0·4–5 m) above ground in horizontal fork of small tree, or where two or more horizontal twigs cross, often where a few large dead leaves trapped and which serve to conceal nest. Clutch 2 eggs; no information on incubation and nestling periods.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Generally common; apparent declines in N & S parts of range, implying that it is less common than it used to be in parts of Kenya and S Mozambique. Occurs in a number of protected areas, including Arabuko-Sokoke and Shimba Hills Forest Reserves, in Kenya, East and West Usambara Forest Reserves (and numerous coastal forest reserves) and the Selous Game Reserve, in Tanzania, and Gorongosa National Park, in Mozambique.
Bibliography. Britton (1972, 1980), Brown & Britton (1980), Caldwell-Barr (2002), Clancey (1996), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Ginn *et al.* (1989), Hall & Moreau (1970), Harrison *et al.* (1997), Irwin (1981, 2004), Jackson & Sclater (1938), Karr (1976), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1963), Maclean (1993), Mlingwa (1993), Parker (1999), Romdal (2001), Sclater & Moreau (1932), Seddon *et al.* (1995), Stevenson & Fanshawe (2002), Tarboton (2001), Turner & Zimmerman (1979), Vernon & Dean (2005a), Vernon *et al.* (1990), Zimmerman *et al.* (1996).

Genus *BLEDA* Bonaparte, 1857

86. **Red-tailed Bristlebill**



Bleda syndactylus

French: Bulbul moustac **German**: Rotschwanzbleda **Spanish**: Bulbul Bigotudo
Other common names: (Common) Bristlebill

Taxonomy. *Dasycephala syndactyla* Swainson, 1837, Sierra Leone.
Proposal that present species forms a species pair with *B. eximius* undermined by recent molecular evidence, which suggests that it is sister-taxon to the rest of genus. Moreover, these data do not support the traditional subspecific treatment as listed below, but indicate a more complex situation; pending further study, however, it is considered better to adopt an orthodox approach. Racial affiliation of birds in Angola uncertain, provisionally included in *woosnami*. Otherwise, race *nandensis* (described from N Nandi Forest, in W Kenya), is only very slightly more yellow below than *woosnami*, and regarded as a synonym of latter; *multicolor* (SE Nigeria E to W DRCongo) is not satisfactorily distinguishable from nominate. Species name sometimes given as *syndactyla*, but genus is masculine. Two subspecies recognized.

Subspecies and Distribution.
B. s. syndactylus (Swainson, 1837) – Sierra Leone E to W DRCongo (Bangui, Lukolela, Tshuapa).
B. s. woosnami Ogilvie-Grant, 1907 – E DRCongo (Kasai, Lualaba, Upper Congo), S Sudan, Uganda, W Kenya, N Angola and extreme NW Zambia.

Descriptive notes. 20·5–23 cm; male 36–57 g, female 35–49·5 g. Striking, robust bulbul with strong bill, well-developed rictal bristles. Nominate has side of face olive-green, darker stripe running from base of bill down side of throat, sweeping up onto lower rear edge of ear-coverts; lores dirty olive-yellow, half-moon of bare blue-grey skin above eye (equally wide in front and

behind eye); rest of head, and upperparts, olive-green to olive-brown, bright rufous uppertail-coverts and tail contrasting with back; bright yellow below, slightly paler on undertail-coverts, washed olivaceous on breast and flanks; iris red, red-brown or chestnut-brown; bill blue-black or dark brown above, paler grey or bluish below; legs pale blue-grey, red-brown or greyish-pink. Distinguished from other members of genus by tail colour, also voice. Sexes alike, female on average smaller than male. Juvenile is largely russet above and on flanks, with yellow orbital skin, yellow cutting edges of bill and gape, dull yellowish legs. Race *woosnami* is more intensely yellow below than nominate. Voice. Song in W of range a series of melancholy, vibrant syllables on same pitch, ending with "turrrruuuu-turrrruuuu-turrruuuu"; in E a series of 4–5 quavering, descending notes, "kweee-kweee-kweee-kweee". Calls include nasal "kyow" or "pyeeuw" and hard "chup". Less vocal than *B. canicapillus* and *B. eximius*.

Habitat. Lowland evergreen and semi-deciduous forest, gallery forest, dense thicket and forest–savanna mosaic, and old secondary forest; mainly in lowlands, but recorded to 2150 m in E Africa and 1450 m in Liberia.

Food and Feeding. Arthropods, including orthopterans, beetles (Coleoptera), mantids, termites (Isoptera), cockroaches (Blattodae), cicadas (Cicadidae), centipedes (Chilopoda), millipedes (Diplopoda) and spiders (Araneae); also frogs and toads, and some fruit. Found in pairs or small family groups; frequently found in mixed-species parties, and regularly attracted by *Dorylus* ant swarms. Large size and heavy bill enable it to take relatively large prey and to dominate in many interspecific encounters, e.g. around ant columns. Shy and retiring. Forages at or near ground level, rarely above 3–5 m, and keeps largely to undergrowth. Feeds from low vegetation, trunks and fallen wood, and at ground level, turning over leaves and other debris; also makes short aerial sallies. Uses horizontal to vertical perches. Extent of territoriality unclear; more than one pair or family group can be found around ant swarms, where a dominance hierarchy is apparently established, dominance at any one time determined by the pair the home range of which is occupied by the ants; ringed individuals did not follow ants for more than 200 m. Where or when ant swarms are few, may be more strictly territorial.

Breeding. Birds in breeding condition in Mar–Apr, Aug–Sept and Nov and fledgling in Oct in Liberia; dependent juvenile in Jan in Ivory Coast; laying Oct–Dec (breeding condition also Mar, Jul–Aug) in Cameroon, Oct–Mar (peak Jan–Feb) in Gabon, Sept–Oct (breeding condition also Jul) in DRCongo, and Jan, Mar, Jun, Aug and Oct in Sudan; breeding condition Sept–Oct and juveniles Jan–Feb in Angola; nesting recorded Apr–May and Aug, in breeding condition Jan–Feb and Jun and fledgling in Dec in Uganda. Monogamous. Territorial. Nest c. 10 cm in diameter and 5 cm deep, resembles bundle of dead leaves, internal cup shallow or more funnel-shaped, outer layer built from supple twigs and cobwebs, inner layer of large dead leaves, lined with slender twigs, fibres and tendrils, bottom in particular lined with hyphae of *Marasmius* fungus (helps to bind structure together); placed 1–3·5 m above ground in dense foliage of low understorey bush. Clutch 2 eggs, rarely 1; incubation by female; no information on incubation and nestling periods. Of 14 nests in Gabon, 11 were destroyed, one young fledged from each of the three surviving nests.

Movements. Resident. Marked site-fidelity recorded in Gabon: 16 of 20 ringed individuals retrapped at same site at least once over a 6-month period following ringing.

Status and Conservation. Not globally threatened. Variously rare, uncommon or common within its large range. Probably under-recorded in at least some areas as a result of its secretive behaviour and the fact that it is not particularly vocal (compared with *B. canicapillus* and *B. notatus*). Estimated densities of 15–18 pairs/km² in Gabon. Occurs in numerous protected areas, such as Sapo National Park, in Liberia, Taï Forest National Park, in Ivory Coast, Kakum National Park, in Ghana, Korup National Park, in Cameroon, Nouabalé-Ndoki National Park, in PRCongo, Salonga National Park, in DRCongo, and Semliki National Park, in Uganda.

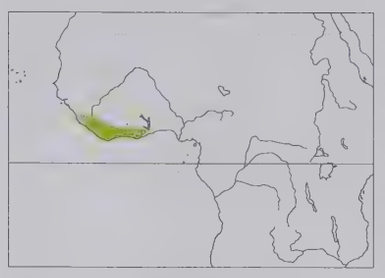
87. Green-tailed Bristlebill

Bleda eximius



French: Bulbul à queue verte **German**: Grünschwanzbleda **Spanish**: Bulbul Coliverde

Taxonomy. *Trichophorus eximius* Hartlaub, 1855, Dabocrom, Ghana.

Suggestion that this forms a species pair with *B. syndactylus* undermined by recent molecular evidence. Was previously treated as conspecific with *B. notatus*, but recent acoustic and morphological studies indicate that the two are separate species; taxonomic confusion resulted in uncertainty over which of the two was involved in published observations in some of the earlier literature. Species name sometimes given as *eximia*, but genus is masculine. Monotypic.

Distribution. Sierra Leone E to SW Ghana.

Descriptive notes. 21·5–23 cm; male 46–52·5 g, female 42–46·5 g. Stocky, handsome bulbul, with strong bill, well-developed rictal bristles. Side of face is olive-green, darker stripe from base of bill down side of throat, sweeping up onto lower rear edge of ear-coverts; lores dull olive-yellow, half-moon of blue-grey skin above eye (widest behind eye), small feathered yellowish postocular spot; uniform olive-green above, including tail, except for narrow yellow tips of outer three pairs of rectrices, extent of yellow greatest (c. 10 mm) on outer pair and decreasing inwards; bright rich yellow below, except for olive wash on breast side and flanks; iris chestnut-brown; bill dark blue-grey, paler or bluish below; legs whitish-flesh, tinged blue. Distinguished from *B. syndactylus* by

yellow-tipped green tail, and from *B. canicapillus* by green head and neck, bare skin around eye, yellowish lores, narrower yellow tail tips, from both also by voice. Sexes alike, female on average smaller than male. Juvenile undescribed. Voice. Song a series of pure, vibrant whistled notes, "hee-huu-huu-hu-heeu", rather similar in tone to those of *B. syndactylus*. Calls include abrupt, nasal "kyop", sometimes followed by fast "kiuwkiuwkiuwkiuwkiu".

Habitat. Lowland evergreen and semi-deciduous forest and older secondary forest; rarely to 1450 m in Liberia.

Food and Feeding. Arthropods, including beetles (Coleoptera), ants (Hymenoptera), caterpillars, spiders (Araneae) and millipedes (Diplopoda); also small frogs. Singly or in pairs; often joins mixed-species parties, and regularly attends *Dorylus* ant swarms. Very shy and unobtrusive; forages at or near ground level, rarely above 3 m.

Breeding. In Liberia, fledgling observed in Oct, peak vocal activity Aug–Oct and birds in breeding condition in Jun–Aug, Oct and Dec; in breeding condition in Sept in Ivory Coast. No other information.

Movements. Resident.

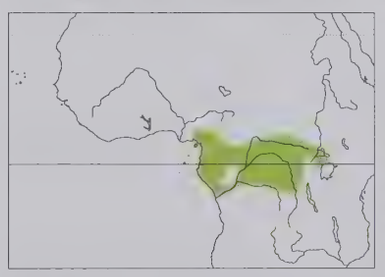
Status and Conservation. VULNERABLE. Restricted-range species: present in Upper Guinea Forests EBA. Generally rare throughout its range; locally common in Liberia. The least common bristlebill within the region; certainly the least vocal, which probably results in its being under-recorded; most often detected through use of mist-nets. Forest habitat in region is subject to logging and to consequent settlement and smallholder agriculture. Occurs in several protected areas, including Western Area Peninsula Non-hunting Forest Reserve, in Sierra Leone, Sapo National Park, in Liberia, Nimba Nature Reserve, in Guinea, Taï Forest National Park, in Ivory Coast, and Kakum National Park, in Ghana.

Bibliography. Bannerman (1936, 1953), Beresford (2002), Borrow & Demey (2001), Britton (1972), Butchart & Stattersfield (2004), Chappuis & Érard (1993), Collar *et al.* (1994), Colston & Curry-Lindahl (1986), David & Gosselin (2002b), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Fishpool *et al.* (1994a), Gartshore *et al.* (1995), Gatter (1997), Grimes (1987), Hall & Moreau (1970), Karr (1976), Keith *et al.* (1992), Mackworth-Praed & Grant (1973), Rainey & Lachenaud (2002), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Thiollay (1985), Waltert *et al.* (1999), Willis (1983).

88. Lesser Bristlebill

Bleda notatus

French: Bulbul jaunelore **German**: Kleiner Grünschwanzbleda **Spanish**: Bulbul Manchado



Taxonomy. *Trichophorus notatus* Cassin, 1856, Moonda River, Gabon.

Until recently treated as a race of *B. eximius*, but acoustic and morphological data indicate that it is a separate species; taxonomic confusion resulted in uncertainty over which of the two was involved in published observations in some of the earlier literature. As a consequence of these findings, considered to form a superspecies with *B. canicapillus*. Molecular evidence from more recent work supports these treatments. It further suggests that race *ugandae* may also merit species rank, a view reinforced by some morphological and (less convincingly) acoustic data; additional study required. Species name sometimes given as *notata*, but genus is masculine. Two subspecies recognized.

Subspecies and Distribution.

B. n. notatus (Cassin, 1856) – extreme SE Nigeria and Bioko I E to SW Central African Republic, S to lower R Congo.

B. n. ugandae van Someren, 1915 – SE Central African Republic, DRCongo (except lower reaches of R Congo), extreme SW Sudan and Uganda.

Descriptive notes. 19·5–21 cm; 28·5–40·7 g (nominate), male 37–48 g, female 33–39 g (*ugandae*). Stocky, handsome bulbul, with fairly strong bill, well-developed rictal bristles. Nominate race has lores and preorbital area yellow, ill-defined postorbital area grey or yellowish-grey, narrow grey feathered eyering, dark olive-green cheeks and ear-coverts; small patch of yellow feathering at base of lower mandible, abruptly becoming almost blackish and forming indistinct blackish moustachial stripe extending from near gape, sweeping up onto lower rear edge of ear-coverts; rest of head and entire upperparts olive-green; tail olive-green, outer four (sometimes three) pairs of rectrices with broad yellow tips, depth of yellow greatest on outermost (c. 20–23 mm), decreasing inwards (10 mm on T3, restricted to outer web); rich, bright yellow below, dark olive-green wash on flanks and side of breast (sometimes extending fully across breast); iris brown, dark brown or red-brown; bill blackish above, blue-grey below; legs grey, blue-grey or pinkish-grey. Distinguished from *B. canicapillus* by green (not grey head), yellow (not grey) loral spot. Sexes alike, female on average smaller than male. Juvenile is mostly dark rufous, base and cutting edges of bill yellow, legs yellowish, iris dull brown. Race *ugandae* is larger than nominate (male wing on average c. 10 mm longer), has bright yellow eyes, duller dirty olive-yellow lores, and in at least some populations broader yellow tips of outer tail feathers (c. 22–30 mm on outermost, decreasing to c. 12–15 mm on T3). Voice. Song of nominate race tremulous and descending in pitch, somewhat reminiscent of that of *B. syndactylus* but lacking latter's melancholy quality; calls include hard, repeated "chup" and "chiup", sometimes followed by "trrrrrrrtttt" rattle, and "whew", in combination may become "chup chup whéé chuw chuw". Song of *ugandae* less well known, but includes sharp "chup-chup-chup" notes followed by clear rolling series of cheerful "whéé-oo-whéo-o-whéé-oo" notes on descending scale, reminiscent of *B. canicapillus*; also includes lively phrases such as "chup-chwe-chwe-we-we-chóówe-chóówe".

Habitat. Lowland evergreen and semi-deciduous forest, swamp-forest, forest–savanna mosaic and secondary forest; mainly in lowlands, to 1250 m in Uganda.

Food and Feeding. Arthropods, including orthopterans, beetles (Coleoptera), butterflies (Lepidoptera), caterpillars, ants (Hymenoptera), spiders (Araneae); also small frogs, and some fruit. Mainly

On following pages: 89. Grey-headed Bristlebill (*Bleda canicapillus*); 90. Western Bearded Greenbul (*Criniger barbatus*); 91. Eastern Bearded Greenbul (*Criniger chloronotus*); 92. Red-tailed Greenbul (*Criniger calurus*); 93. Yellow-bearded Greenbul (*Criniger olivaceus*); 94. White-bearded Greenbul (*Criniger ndussumensis*).

in small family groups, typically of a pair and one young; often joins mixed-species flocks. Generally skulking and secretive, but vocal. Forages mostly at or near ground level, usually below 3 m. Prefers mostly horizontal perches. Takes food mostly from the ground, in short sallies or by hopping; also from tree trunks and low vegetation. Pecks at ground prey and tosses leaves. Regularly attends *Dorylus* ant swarms; more than one pair or group may be attracted to large columns; in studies, ringed individuals were replaced by unringed ones once the column had moved 200 m. Spreads tail to show yellow corners in interactions.

Breeding. Breeds in all months in DRCongo, probably also in Cameroon; in most months, peak in Jan–Feb short dry season (only long dry season of Jun–Sept avoided) in Gabon. Monogamous. Estimated territory size in PRCongo 2 ha under closed canopy; pairs in Gabon live in overlapping home ranges, do not defend territories. Nest built by both sexes, a simple bundle of dried leaves held together and attached to supporting branch with living strands of *Marasmius* fungus, lined with skeletonized leaves and more *Marasmius*, generally hidden in larger bundle of dead leaves 0·5–3 m above ground in shrub in open forest. Clutch 2 eggs, rarely 1; incubation by female only, period 14 days; young brooded and fed by both parents, nestling period 13–14 days; usually only one chick fledges, remains with parents for at least 8–9 months. In Gabon, 82% of nests were destroyed, of 15 successful nests average 1·3 young raised per nest.

Movements. Resident; striking site-fidelity in Gabon, where 76% of ringed individuals recaptured at ringing site and none caught more than a few hundred metres distant. Young apparently do not disperse far; two adults recaptured at site where reared one year earlier.

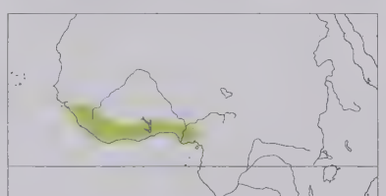
Status and Conservation. Not globally threatened. Generally widespread and common across its range. Density in Gabon estimated at 1·2 birds/ha. Adapts to secondary habitats. Occurs in a number of protected areas, such as Korup National Park, in Cameroon, Nouabalé-Ndoki National Park, in PRCongo, Salonga National Park, in DRCongo, and Semliki National Park, in Uganda.

Bibliography. Bannerman (1936, 1953), Beresford (2002), Borrow & Demey (2001), Britton (1972, 1980), Brosset (1971a, 1971b, 1981c), Brosset & Érard (1986), Carswell (1986), Cave & MacDonald (1955), Chapin (1953), Chappuis (1975), Chappuis & Érard (1993), Christy & Clarke (1994), David & Gosselin (2002b), Dean (2000), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1991), Elgood *et al.* (1994), Fishpool & Evans (2001), Hall & Moreau (1970), Jackson & Sclater (1938), Keith *et al.* (1992), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1960, 1973), Nikolaus (1987, 1989), Pérez del Val (1996), Prigogine (1971), Rand *et al.* (1959), Rodewald *et al.* (1994), Sargeant (1993), Schouteden (1957), Stevenson & Fanshawe (2002), Willis (1983).

89. **Grey-headed Bristlebill**

Bleda canicapillus

French: Bulbul fourmilier **German**: Graukopfbleda **Spanish**: Bulbul Hormiguero



Taxonomy. *Trichophorus canicapillus* Hartlaub, 1854, Sierra Leone.

Recently shown by acoustic and morphological studies to form a superspecies with *B. notatus*, a relationship hitherto unrecognized; the two appear to meet in SE Nigeria (Cross River National Park region) and SW Cameroon (Takamanda Forest Reserve). Species name sometimes given as *canicapilla*, but genus is masculine, and in any case this species name is invariable. Two subspecies recognized.

Subspecies and Distribution.

B. c. morelorum Érard, 1992 – W Gambia and SW Senegal.

B. c. canicapillus (Hartlaub, 1854) – Guinea-Bissau E to SE Nigeria (also isolated population on Jos Plateau) and extreme SW Cameroon (Takamanda).

Descriptive notes. 20·5–22 cm; male 39·5–46·5 g, female 36–40·5 g. Stocky bulbul with fairly strong bill, well-developed rictal bristles. Nominate race has slate-grey head and neck, contrastingly paler grey lores and small postorbital area, narrow grey (non-contrasting) feathered eyering; small patch of whitish feathering at base of lower mandible, abruptly becoming almost blackish and forming indistinct moustachial stripe, sweeping up onto lower rear edge of ear-coverts; upperparts and tail olive-green, yellow tips on outer three pairs of rectrices, depth of yellow 12–15 mm, greatest on outermost pair; chin and throat pale yellowish, underparts brighter yellow, breast side and flanks washed olive-green; iris brown to reddish; bill blackish above, blue-grey below; legs pale blue-grey, sometimes tinged pinkish. Distinguished from *B. notatus* by grey (not green) head, grey (not yellow) loral spot; from *B. eximius* also by wider yellow tail tips, no bare skin around eye. Sexes alike, female on average smaller than male. Juvenile poorly known, has cutting edges and base of bill yellow, legs grey-pink. Race *morelorum* is paler yellow below than nominate, head also paler grey, upperparts browner, less green. Voice. Song far-carrying, with cheerful, ringing quality, typically consisting of loud initial note, brief pause, followed by a series of "chéépo" notes on descending scale. Other characteristic notes include loud "chéép" or "chríup" and "kyuw" or "peeuw", often repeated in long series.

Habitat. Lowland evergreen and semi-deciduous forest, gallery forest, forest–savanna mosaic, woodland thicket and secondary forest; to at least 1000 m.

Food and Feeding. Arthropods, including orthopterans, termites (Isoptera), ants (Hymenoptera), millipedes (Diplopoda), spiders (Araneae) and similar; small frogs and fruit also recorded as taken. Mainly in pairs or small family groups; often joins mixed-species flocks, and regularly attends *Dorylus* ant swarms. Generally skulking and shy, but usually vocal. Forages mostly at or near ground level, usually below 2 m, occasionally to 5 m. Prefers angled perches, from where makes sallies for insects to the ground, dead wood, tree trunks and low vegetation; also gleans from vegetation. Flicks wings and flicks tail up to horizontal (tail spots conspicuous).

Breeding. Birds in breeding condition in Jan in Senegal, Jun in Gambia, May, Aug–Sept and Dec in Sierra Leone, Jul–Aug (and nest-building observed in Nov) in Liberia, May–Jun in Ivory Coast and Jun in Nigeria. Only one nest described, an insubstantial, fibre-lined, open cup of dead leaves, on base of dry twigs, externally 11 cm in diameter and 9 cm deep, hanging 1·6 m above ground among trailing vines in low bush. Clutch 2 eggs; no information on incubation and nestling periods.

Movements. Largely sedentary; individual found in a building in Ghana may indicate some local movement.

Status and Conservation. Not globally threatened. Generally common; the commonest and most widespread bristlebill in W Africa. Liberian population estimated to be at least 120,000 pairs. Apparently adapting well to secondary habitats. Occurs in numerous protected areas, including Loma Mountains Non-hunting Forest Reserve, in Sierra Leone, Sapo National Park, in Liberia, Nimba Nature Reserve, in Guinea, Taï Forest National Park, in Ivory Coast, Bia National Park, in Ghana, and Okomu National Park, in Nigeria.

Bibliography. Bannerman (1936, 1953), Barlow *et al.* (1997), Beresford (2002), Borrow & Demey (2001), Britton (1972), Chappuis (1975), Chappuis & Érard (1993), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), David & Gosselin (2002b), Demey & Fishpool (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Érard (1992), Fishpool & Evans (2001), Fishpool *et al.* (1994a), Gartshore *et al.* (1995), Gatter (1997), Gore (1990), Grimes (1987), Hall & Moreau (1970), Halleux (1994), Johnson, D.N. Genus *CRINIGER* Temminck, 1820

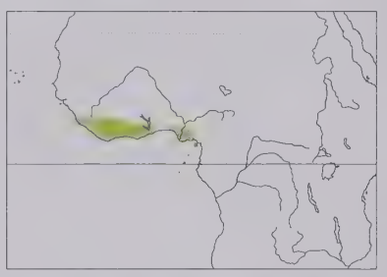
90. **Western Bearded Greenbul**

Criniger barbatus

French: Bulbul crinon **German**: Westlicher Haarbülbülm **Spanish**: Bulbul Barbado



Taxonomy. *Trichophorus barbatus* Temminck, 1821, Sierra Leone.

Genus previously considered close to *Alophoixus*, and latter often merged with it; recent molecular evidence, however, strongly supports the view that the relationship between the two groups is remote, despite close similarity in appearance. Forms a superspecies with *C. chloronotus*, and often considered conspecific, but exhibits appreciable vocal as well as plumage differences. Race *ansorgeanus* is morphologically and geographically intermediate between nominate race and *C. chloronotus* and could arguably, on current knowledge, equally be placed with latter; better knowledge of its vocalizations would help to resolve its true taxonomic position. Two subspecies recognized.

Subspecies and Distribution.

C. b. barbatus (Temminck, 1821) – Sierra Leone and SE Guinea E to SW Togo and S Benin.

C. b. ansorgeanus Hartert, 1907 – S Nigeria.

Descriptive notes. c. 22 cm; male 41–48 g female 38–43 g. Large bulbul with heavy bill, conspicuous yellow throat feathers frequently puffed out, lax crown feathers raised in display; upperside appearing rather untidy, mottled grey-brown. Nominate race has grey lores, inconspicuous pale grey narrow feathered eyering, olive-brown ear-coverts with conspicuous whitish feather shafts; feathers of head grey centrally with green feather fringes, upperparts olive-green, with grey feather centres on mantle; tail slightly browner-tinged than back but not obviously contrasting; upperwing-coverts and flight-feathers olive-green, browner on inner webs of primaries and outer secondaries; conspicuous yellow throat, contrasting with rest of plumage; breast grey with green feather fringes and pale shaft streaks, belly, flanks and undertail-coverts olive-yellow with buffy tinge; iris dark brown; bill black, slightly paler lower mandible; legs dark grey to black. Distinguished from *C. olivaceus* by larger size, more mottled appearance, greyer underparts, no blue orbital ring. Sexes alike, female on average smaller than male. Juvenile is browner above than adult, plain brownish below, throat paler yellow, gape yellow. Race *ansorgeanus* is smaller on average than nominate, has throat much paler yellow (feather bases white), more yellow on belly, gingery undertail-coverts, rufous uppertail (contrasting with back), wider blue-grey eyering contrasting with more olive-green head, juvenile with rusty-brown secondary coverts and secondary tips, paler throat, yellower breast, cinnamon undertail-coverts, grey-brown iris, greyish-olive legs, olive-yellow lower mandible. Voice. Most common song a frequent, clear, far-carrying, disyllabic whistle, "teruu twéééur"; calls include loud "kyuw" and hard "tsik". Voice of race *ansorgeanus* less well known, but includes lively "chew-cheeuw-chéééúw-eer".

Habitat. Lowland evergreen and semi-deciduous forest, swamp-forest, gallery forest and larger forest patches in forest–savanna mosaic; found in older secondary growth, but not in younger regrowth. Recorded to 1250 m in Liberia.

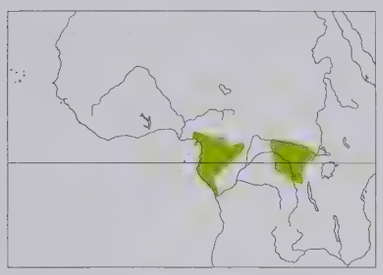
Food and Feeding. Mainly insectivorous, but berries and seeds also regularly taken. Usually in small, noisy groups; often a conspicuous component of mixed-species parties, and frequently attends *Dorylus* ant swarms. Forages mainly in lower stratum, but not on the ground, up to 10 m, mainly below 5 m, and usually in relatively open areas. Favours sloping perches in shrubs and small trees. Gleans from leaves and makes short aerial sallies to take berries and other items. Frequently puffs out throat feathers, thought possibly to be a contact signal.

Breeding. Laying recorded in Jan in Nigeria; dependent fledglings in Jan and juveniles in Oct and Mar–Apr in Liberia; juveniles in Jul in Ghana; birds in breeding condition recorded in Dec–Apr. No other information.

Movements. No information; thought to be sedentary.

Status and Conservation. Not globally threatened. Not uncommon to common throughout most of range, wherever suitable habitat remains; rare in extreme SW Togo. Recently recorded for first time in S Benin. Occurs in a number of national parks, including those of Sapo, in Liberia, Taï Forest, in Ivory Coast, and Bia and Kakum, in Ghana; also in other protected areas, such as Loma Mountains Non-hunting Forest Reserve, in Sierra Leone, and Omo Forest Reserve (part of which is a Strict Nature Reserve), in Nigeria.

Bibliography. van den Akker (2003), Bannerman (1936, 1953), Beresford (2002), Borrow & Demey (2001), Britton (1972), Chappuis (1975), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fishpool & Evans (2001), Fishpool *et al.* (1994a), Gartshore *et al.* (1995), Gatter (1997), Grimes (1987), Hall & Moreau (1970), Halleux (1994), Karr (1976), Keith *et al.* (1992), Louette (1981), Mackworth-Praed & Grant (1973), Marchant (1953), Pasquet *et al.* (2001), Serle (1957), Thiollay (1985), Waltert *et al.* (1999).



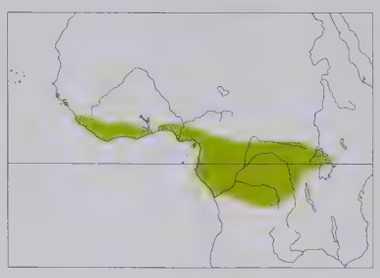
91. **Eastern Bearded Greenbul**

Criniger chloronotus

French: Bulbul à dos vert **German**: Östlicher Haarbülbül **Spanish**: Bulbul Dorsiverde

Other common names: Green-backed/Congo/White-throated Bulbul

Taxonomy. *Trichophorus chloronotus* Cassin, 1859, Camma River, Gabon.
Genus previously considered close to *Alophoixus*, and latter often merged with it; recent molecular evidence, however, strongly supports the view that the relationship between the two groups is remote, despite close similarity in appearance. Forms a superspecies with *C. barbatus*, and often considered conspecific, but exhibits appreciable vocal and plumage differences. Race *ansorgeanus* of latter is morphologically and geographically intermediate between nominate race of that species and present species and could arguably, on current knowledge, equally be placed with this species; better knowledge of its vocalizations would help to resolve its true taxonomic position. Proposed race *weileri* (from Ituri, in NE DRCongo) described on basis of somewhat darker overall coloration, but not satisfactorily distinguishable, as variation not constant. Monotypic.
Distribution. Extreme SE Nigeria E to W Central African Republic, S to W PRCongo and N Angola (Cabinda); also N & E DRCongo (S to Itombwe) E to extreme W Uganda.



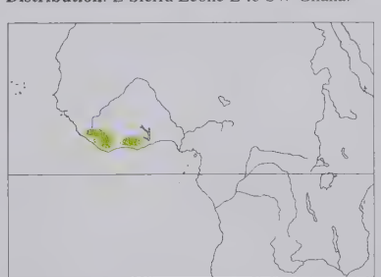
Descriptive notes. c. 22 cm; 39–54 g. Large bulbul with heavy bill, conspicuous long white throat feathers often puffed out, lax crown feathers raised in display. Head feathers are dark grey with black centres (appearing darker and more mottled than nape), feathers of ear-coverts with obvious white shafts, giving scaly appearance; lores grey, paler than rest of head, non-contrasting narrow grey feathered eyering; upperparts olive-green, contrasting bright rufous uppertail-coverts and tail; wings olive-green, primaries and secondaries browner on inner webs; throat white, contrasting conspicuously; breast pale grey, becoming yellowish-olive on belly and flanks, and gingery-yellow on undertail-coverts; iris dark brown or dark red; bill dark blue-grey, slightly paler lower mandible; legs dark grey to black. Differs from *C. calurus* in larger size, more brightly rufous tail, grey (not olivaceous) breast, duller yellow belly. Sexes alike, female on average smaller than male. Juvenile has yellow gape. Voice. Soft, quavering, mournful 2-note song, "houuu-wuuuuuuuh", second note higher-pitched and extended.
Habitat. Evergreen and semi-deciduous forest and swamp-forest; mainly in lowlands, but recorded to 1800 m in E DRCongo.
Food and Feeding. Arthropods, including orthopterans and beetles (Coleoptera); also some fruit. Usually in shy but noisy groups of 3–5 individuals, in dry season up to 7–8; more rarely, solitary or in pairs. Sometimes joins mixed-species parties, and often follows *Dorylus* ant swarms. Forages mainly in lower stratum, usually below 15 m, sometimes higher during dry season. Gleans insects from leaves and, especially, from cracks in bark; likes matted vines and tangles of small branches. Frequently puffs out throat feathers, thought possibly to be a contact signal.
Breeding. Aug and Nov–Mar (mainly in Dec–Mar short dry season) in Gabon; laying recorded Dec–May, but breeding throughout year suspected, in DRCongo; birds in breeding condition in Mar and Aug in Cameroon. May breed co-operatively. Territorial. Nest a sturdy shallow cup, outer wall of twigs and moss, inner wall of thin plant stems, lined with hyphae of *Marasmius* fungus, stems up to 30 cm long of epiphytic fern *Microgramma owariensis* incorporated into rim (leaves are left on stem, remain green throughout), one nest had external diameter 9·2 cm and internal 7 cm; built 0·5–2 m above ground, often on terminal shoot of the understorey shrub *Alchornea floribunda*, nest becomes bound to base of wood fragments and dead leaves by growth of a fungal mycelium. Clutch 2 eggs, rarely 1; incubation by female only, period at least 14 days; no information on nestling period. Of 35 nests observed, 74% were preyed on; of nine successful nests, three produced two fledglings each and six produced only one each.
Movements. Sedentary within apparently large home range; of 23 individuals ringed in Gabon, only five were retrapped, over intervals of up to 49 months.
Status and Conservation. Not globally threatened. Widespread and generally fairly common. Estimated density in Gabon 7–8 groups/km². Occurs in a number of national parks, including those of Cross River, in Nigeria, Korup, in Cameroon, Lopé, in Gabon, Nouabalé-Ndoki, in PRCongo, and Semliki, in Uganda; present also in Okapi Faunal Reserve, in DRCongo.
Bibliography. Bannerman (1936, 1953), Beresford (2002), Borrow & Demey (2001), Britton (1980), Brosset (1971a, 1971b), Brosset & Érard (1986), Chapin (1953), Chappuis (1975), Christy & Clarke (1994), Dean (2000), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1991), Elgood *et al.* (1994), Fishpool & Evans (2001), Hall & Moreau (1970), Karr (1976), Keith *et al.* (1992), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1960, 1973), Pasquet *et al.* (2001), Prigogine (1971), Rodewald *et al.* (1994), Sargeant (1993), Schouteden (1957), Stevenson & Fanshawe (2002).

92. Red-tailed Greenbul

Criniger calurus

French: Bulbul à barbe blanche **German**: Swainsonbülbül **Spanish**: Bulbul Colirrojo
Other common names: White-bearded Greenbul

Taxonomy. *Trichophorus calurus* Cassin, 1856, Moonda River, Gabon.
Genus previously considered close to *Alophoixus*, and latter often merged with it; recent molecular evidence, however, strongly supports the view that the relationship between the two groups is remote, despite close similarity in appearance. Has often been regarded as conspecific with *C. ndussumensis* owing to similarity in appearance, but the two differ both vocally and morphologically. Published reports of hybridization between latter and race *emini* of present species in NE DRCongo seem to be based on observation of individuals apparently showing combination of characters then thought to be restricted to each form. Three subspecies recognized.
Subspecies and Distribution.
C. c. verreauxi Sharpe, 1871 – SW Senegal and SE Guinea-Bissau E to SW Nigeria.
C. c. calurus (Cassin, 1856) – SW Nigeria E to W DRCongo, also Bioko I.
C. c. emini Chapin, 1948 – W DRCongo and NE Angola E to Uganda and W Tanzania.
Descriptive notes. c. 20 cm; 26–32·5 g (nominate); male 33–40·5 g, female 33–37·5 g (*verreauxi*), male 22–34 g, female 25–30 g (*emini*). Handsome bulbul with conspicuous tufted white throat feathers, often puffed in display. Nominate race has crown dark olive-brown, slightly greyer on hindneck; ear-coverts with white feather shafts (slightly scaly effect); wide area in front of, above and behind eye sparsely feathered pale blue-grey, lores similarly coloured, creating conspicuous spectacled appearance; upperparts olive-green, contrasting rufous uppertail-coverts and tail; throat white; breast side, flanks and narrow band across upper breast dull olive-green, remainder of breast and belly much brighter yellow, undertail-coverts sometimes slightly more rufous; iris red-brown; bill blue-grey, darker dorsally; legs blue-grey. Distinguished from very similar *C. ndussumensis* by marginally brighter tail, slightly longer and broader bill, but mainly by voice; from *C. chloronotus* by smaller size, brighter underparts, duller tail. Sexes alike, female on average smaller than male.



Juvenile differs from adult in having dull cinnamon fringes on upperwing-coverts. Race *verreauxi* is darker green above than nominate, uppertail-coverts and tail with little rufous (in the field appearing concolorous with back); *emini* is intermediate, similar to nominate but with tail-coverts and tail duller rufous. Voice. Song a cheerful, rising "chup-chup-chwirulup" or "tsik-tyu-tyip"; also a rapid series, "tyutyu-tyutyu-tyip-tyiptyip", and alarm a sharp "tsik".
Habitat. Evergreen and semi-deciduous forest, gallery forest and forest–savanna mosaic; also older secondary forest and edge habitats. Mainly lowlands, but recorded to 1000 m in Liberia, 950 m in Cameroon, 1750 in DRCongo and 1500 in Uganda.
Food and Feeding. Arthropods, including beetles (Coleoptera), bugs (Hemiptera), orthopterans, lepidopterans (including caterpillars), ants (Hymenoptera), spiders (Aranea); also small lizards; some berries and other fruit (including *Ficus*) and seeds. Occurs in groups of 3–10 individuals, sometimes a dozen. A conspicuous and constant component of mixed-species parties; sometimes attends *Dorylus* ant swarms. Forages from low to middle levels, 4–20 m; uses relatively narrow, more or less horizontal branches and twigs as perches from which to glean food from leaf surfaces, crevices, tangles of dead leaves and vines, etc. Also makes aerial sallies to pick berries and to take insects off leaves.
Breeding. Juveniles in Nov–Jan and birds in breeding condition Jun–Jul, Sept and Nov in Liberia; dependent juvenile in May in Ivory Coast; laying in Feb, Apr–Aug and Dec in Cameroon and in Feb–Mar and Nov (and breeding condition Aug) in Bioko; laying in Dec–Feb short dry season (and breeding condition Aug) in Gabon; in breeding condition in Jun in Central African Republic; breeding recorded in all months in DRCongo; laying in Jun, juveniles in Apr and Jul and birds in breeding condition in May and Nov in Uganda. Strongly territorial. Nest a cup made of rootlets and twiglets built on base of stiff dry leaves, and attached by a dense network of cobwebs, one had external diameter 11 cm and internal 6·5 cm; placed 1·8–2·8 m above ground in fork between petiole of a large leaf and main stem of bush. Clutch 2 eggs; incubation by female only, no information on period; chicks fed by both parents, leave nest at 14 days; one newly fledged young seen both to feed itself and to receive food repeatedly from several members of its group. Of four nests in Gabon, one was destroyed, the other three produced two young each.
Movements. Resident. Of 50 individuals ringed in Gabon, 22 were retrapped at same place, one after 25 months and one after 49.
Status and Conservation. Not globally threatened. Common and widespread throughout its extensive range. Estimated to occur in densities of 12 groups/km² in Gabon and 1 bird/5 ha in Nigeria. Adapts well to older secondary habitats. Occurs in numerous national parks, including those of Sapo, in Liberia, Taï Forest, in Ivory Coast, Kakum, in Ghana, Cross River, in Nigeria, Korup, in Cameroon, Lopé, in Gabon, Nouabalé-Ndoki, in PRCongo, Salonga, in DRCongo, and Semliki, in Uganda.

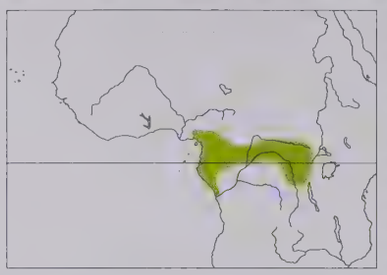
93. Yellow-bearded Greenbul

Criniger olivaceus

French: Bulbul à barbe jaune **German**: Olivrückenbülbül **Spanish**: Bulbul Barbigualdo
Other common names: Yellow-throated Olive Greenbul/Bulbul

Taxonomy. *Trichophorus olivaceus* Swainson, 1837, West Africa.
Genus previously considered close to *Alophoixus*, and latter often merged with it; recent molecular evidence, however, strongly supports the view that the relationship between the two groups is remote, despite close similarity in appearance. Considered by some authors to form a superspecies with *C. ndussumensis*; others regard the two as conspecific, on basis of vocal and behavioural similarities (responds to playback of song of that species). Considerable differences in coloration suggest that, although unquestionably closely related, the two are better treated as distinct species; this supported by results of recent molecular studies, which even suggest that present species is sister-taxon of *C. calurus*, rather than of *C. ndussumensis*. Monotypic.
Distribution. E Sierra Leone E to SW Ghana.

Descriptive notes. c. 18 cm; male 25·5–31·5 g, female 23·5–29·5 g. Relatively small greenbul with puffed-out throat feathers. Head and upperparts, including wings, are olive-green, crown often darker and browner; ear-coverts streaked yellowish-white, lores yellowish, narrow orbital ring of sparse blue-grey feathers; tail faintly washed rufous, not obviously contrasting; throat bright yellow, conspicuous against green underparts, latter becoming yellowish in centre of belly; iris deep brown to red-brown; bill dark grey; legs dark blue-grey. Distinguished from *C. barbatus* by smaller size, lack of grey mottling in plumage of breast, ear-coverts and mantle, contrasting eyering, also shorter-looking throat feathering (less frequently "inflated"). Sexes alike. Juvenile said to be browner above and duller below; one fully grown immature was indistinguishable from adult. Voice. Song 3 short, low-pitched syllables with third slightly stressed, "whut-chruw-chruw", similar in structure to that of *C. calurus* but lower in pitch and sounding less sprightly; indistinguishable from song of *C. ndussumensis*.
Habitat. Largely restricted to primary and well-developed secondary lowland evergreen and semi-deciduous forest; found also in gallery forest in parts of Liberia, but generally absent from this habitat (at least at lower altitude at E end of range). Much less common in logged and young regenerating forest. Recorded up to 900 m.



Food and Feeding. Mainly insectivorous, but small fruits also taken. Occurs singly or, more usually, in pairs, sometimes in small family parties; often in mixed-species flocks, including with its two sympatric congeners. Generally unobtrusive and quiet. Forages mainly at 3–10 m, occasionally up to 25 m, generally higher than *C. barbatus*. Has distinctive habit of often foraging on vertical stems and trunks, clinging to them in a manner reminiscent of European nuthatches (*Sitta*) and also of the E African *Andropadus masukuensis*. Gleans bark; forages in epiphytes and on lianas, often hanging upside-down.
Breeding. Data from Liberia include individual carrying nest material in Sept, downy fledgling and female in breeding condition in Nov, and almost fully grown immature in Jan; dependent young reported in Apr in Sierra Leone and in Apr and Nov in Ivory Coast; birds in breeding condition in May in Guinea. No other information.
Movements. No information; assumed to be sedentary.
Status and Conservation. VULNERABLE. Restricted-range species: present in Upper Guinea Forests EBA. Rare to uncommon across much of its fragmented range. Seems to be commonest in Liberia, where it occurs across much of NW & NE of the country, including Sapo National Park, and national population estimated at 120,000 pairs. In Sierra Leone, population in Gola Forest estimated at 750–1600 individuals; occurs also in the better-protected Loma Mountains Non-hunting Forest Reserve. In Ivory Coast, uncommon in Taï Forest National Park but more common farther E, in the less well-protected Yapo Reserve. Rediscovered in SW Ghana in late 1980s, and recent surveys have shown it to be more widespread than originally thought; recorded in Bia and Kakum National Parks. Earlier reports from Senegal and Mali are now thought to be erroneous. Main threats are logging of forests and consequent settlement and smallholder agriculture.
Bibliography. Allport (1991), Allport *et al.* (1989), Atkinson *et al.* (1996), Bannerman (1936, 1953), Barlow *et al.* (1997), Borrow & Demey (2001), Britton (1972), Butchart & Stattersfield (2004), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Colston & Curry-Lindahl (1986), Demey (2002), Demey & Fishpool (1994), Demey & Rainey (2004), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Field (1979), Fishpool & Evans (2001), Fishpool *et al.* (1994a), Gartshore *et al.* (1995), Gatter (1997), Grimes (1987), Hall & Moreau (1970), Halleux (1994), Keith *et al.* (1992), Mackworth-Praed & Grant (1973), Morel & Morel (1990), Pasquet *et al.* (2001), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Thiollay (1985).

94. White-bearded Greenbul

Criniger ndussumensis

French: Bulbul de Reichenow **German**: Weißbartbülbül **Spanish**: Bulbul Barbiblanco
Other common names: Slender-billed Bearded Bulbul

Taxonomy. *Criniger verreauxi ndussumensis* Reichenow, 1904, Ndussuma country, Kinjawanga and Bellima, near Beni, DRCongo.
Genus previously considered close to *Alophoixus*, and latter often merged with it; recent molecular evidence, however, strongly supports the view that the relationship between the two groups is remote, despite close similarity in appearance. Taxonomic history confused. Sometimes treated, on basis of structural, behavioural and vocal similarities, as a race of *C. olivaceus* (which responds to playback of song of present species), but significant plumage differences suggest that, although clearly closely related, the two are better treated as distinct species; this interpretation supported by results of recent molecular studies. Alternatively, has often been considered conspecific with *C. calurus* because of its close similarity in appearance to sympatric races of latter, but differs in both voice and morphology (suspected differences in foraging behaviour not proven, owing to difficulty of distinguishing between the two species in the field). Published reports of hybridization with *C. calurus* (of race *emini*) in NE DRCongo seem to be based on observation of individuals apparently showing combination of characters then thought to be restricted to each form. Further work needed to clarify the situation. Monotypic.
Distribution. SE Nigeria E to E DRCongo (Semliki and Itombwe), S to coastal PRCongo; not known to occur across much of intervening region in S part of this range.

Descriptive notes. c. 18 cm; 24·5–31 g. Relatively small bulbul with conspicuous tufted white throat feathers, sometimes puffed in display. Has crown olive-brown, greyer on hindneck, white streaking on ear-coverts, contrasting pale blue-grey feathering behind, above and in front of eye; upperparts olive-green, dull rufous-cinnamon uppertail-coverts and tail contrasting with back; conspicuous white throat, contrasting with olive-green upper breast; remainder of breast and belly much brighter yellow, flanks strongly washed dull olive, undertail-coverts cinnamon-buff; iris red-brown; bill blue-grey, darker dorsally; legs blue-grey. Distinguished from extremely similar *C. calurus* (mainly of E races) by reputedly paler (greyish-white) lores, narrower and slightly shorter bill, also by undertail-coverts on average more cinnamon-rufous and flanks more heavily washed olive (but overlap in characters); reliably separated in the field only by voice. Sexes alike, female on average smaller than male. Juvenile undescribed. VOICE. Song 3 short harsh syllables on even, relatively low pitch, emphasis on last syllable, "whut-chruw-chruw" or "chuk-yer-chyer", indistinguishable from that of *C. olivaceus*; song structure resembles that of *C. calurus*, but lower-pitched and lacking latter's sprightly quality. Call a nasal, rather frog-like "quek-quek" or "queg-queg", not recorded for *C. olivaceus*. Alarm "tsik" or "tchic", as for *C. calurus*.
Habitat. Primary and well-developed secondary lowland evergreen and semi-deciduous forest and swamp-forest. Further details lacking, owing to confusion with *C. calurus*.
Food and Feeding. Mainly insectivorous; recorded as taking figs (*Ficus*) in PRCongo. Usually in pairs or family parties; often in mixed-species flocks, often alongside *C. calurus*. Generally unobtrusive and quiet. Further details uncertain, owing to confusion with *C. calurus*. By inference, it is probable that it has same behaviour as its W African vicariant *C. olivaceus*, that of foraging extensively on vertical stems and trunks; birds are commonly seen exhibiting this behaviour in Lower Guinea and Congo Basin forests, and it is likely that reports of *C. calurus* behaving this way refer, in fact, to present species.
Breeding. Fledgling recorded in Feb in Cameroon. No other definite information.
Movements. No information; likely resident.
Status and Conservation. Not globally threatened. Status uncertain, as confused with *C. calurus*; known to be less common and widespread than that species. Range is, however, extensive, and this species is known to occur in numerous protected areas, including Cross River National Park, in Nigeria, Korup National Park, in Cameroon, Nouabalé-Ndoki National Park, in PRCongo, and Okapi Faunal Reserve, in DRCongo.

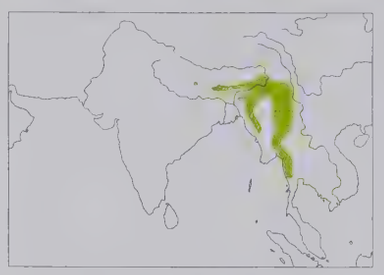
Genus *ALOPHOIXUS* Oates, 1889

95. Finsch's Bulbul

Alophoixus finschii

French: Bulbul de Finsch **German**: Finschbülbül **Spanish**: Bulbul de Finsch
Other common names: Finsch's Bearded/Dwarf (Bearded) Bulbul

Taxonomy. *Criniger finschii* Salvadori, 1871, Borneo.
Genus often merged with *Criniger*; recent molecular evidence, however, strongly supports the view that the relationship between the two is remote, despite close similarity in appearance. Present species highly divergent in terms of morphology, behaviour and voice, possibly merits isolation in monotypic genus; thorough review necessary. Putative race *theiodes* (= *theoides*) only very weakly differentiated. Monotypic.
Distribution. Extreme S Thailand, Peninsular Malaysia, Sumatra and Borneo.



Descriptive notes. 16·5–17 cm; 22–25 g. Medium-sized, dull, unobtrusive bulbul with distinctively short bill. Side of head is brownish-olive, greenish tint on ear-coverts and neck side; cap to uppertail-coverts warm brownish-olive, tail-coverts slightly rufous-tinged; upperwing similar, outer webs of tertials and secondaries brighter and fringed distinctly olive, primaries brownish-olive with green tinge on outer webs; tail uniform dark olive-brown with chestnut tint; chin and throat creamy yellow, forming triangular patch (often puffed out); breast light olive with creamy-yellow feather fringing, darkening to dull grey-green at side and on flanks; belly and undertail-coverts plain creamy yellow, brighter on belly; iris pale yellowish-brown to orange-brown; upper mandible blackish, lower mandible plumbeous; legs dark horn to reddish-brown. Sexes alike. Juvenile apparently very similar to adult. Voice. Not well known. Usually very quiet, but said to give simple series of notes, transcribed as "choi-choi-chong-choi, choi-choi", and a "very musical and pleasant song" (Borneo); existence of this song debatable, and description should be regarded as provisional. Contact calls between foragers include subdued "wek" or "twut", sometimes given in flight; also has loud, nasal, explosive "hwuiikt" and harsh grating "screee" notes, probably as alarm.
Habitat. Usually in primary and selectively logged evergreen forest in lowlands, avoiding heavily logged sites and younger regrowth, but entering secondary growth and mature or overgrown plantations (e.g. cocoa and *Albizia*). Visits forest edges, particularly where fruiting trees abound, but generally avoids isolated trees and larger clearings. From near sea-level to 750 m in Peninsular Malaysia, to 650 m in Sumatra, and to 900 m in Borneo (where it appears to be more common in foothill habitats).
Food and Feeding. A generalist; eats fruit and insects. Especially fond of berries of *Trema* and figs of riverside banyans (e.g. *Ficus microcarpa*); also tall, canopy-cropping fig species, including six of 25 species of *Ficus* (in mean minimum fruit-diameter range 5·4–14·8 mm) in study at Kerau, in Peninsular Malaysia. Usually found singly or in pairs, but occasionally in small parties of up to eight individuals. Forages at all levels, including emergent crowns, but mostly in middle storey and subcanopy; comes lower to fruiting shrubs, saplings and vines, and sometimes visits *ladang* (traditional shrubby agricultural fields) during mass fruiting events. Sometimes accompanies high-level mixed-species foraging flocks, and makes short sallies after large insects from low or high perches.
Breeding. Recorded in Mar–Jul. Nest built by both pair-members; nest undescribed, but pair in mature forest gathered material at canopy level; probably nests higher above ground than do most bulbuls. Fledglings tended by both parents. No other information.
Movements. Presumably resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Generally uncommon or rare; possibly overlooked. Status in Sumatra was, until recently, enigmatic; apart from 12 specimens taken in N of island, the species is now known from C Sumatra, where seen several times near Kerinci-Seblat National Park (in Jambi province) in 1996. Occurs in a range of protected areas, including Hala-Bala Wildlife Sanctuary, in Thailand, Taman Negara National Park and Kerau Wildlife Reserve, in Peninsular Malaysia, and, in Borneo, Danum Valley Conservation Area (Sabah) and Gunung Palung National Park (Kalimantan). In all these areas it is rare or difficult to find, perhaps being most common at Kerau. Because it is restricted to closed-canopy forest at relatively low altitudes, it is more susceptible than are most species to the deforestation which continues apace in the Sundaic realm.
Bibliography. van Balen (2001), Collar *et al.* (2001), Davison (1987), Dickinson *et al.* (2002b), Duckworth & Kelsh (1998), Gibson-Hill (1949), Gore (1968), Holmes (1996, 1997), Hose (1893), Hume (1876a, 1879), Jeyarajasingam & Pearson (1999), Lambert (1989b), Lekagul & Round (1991), MacKinnon & Phillipps (1993), Mann (1987), van Marle & Voous (1988), Medway & Wells (1976), Mitra & Sheldon (1993), Robinson & Kloss (1920), Robson (1996a, 2000), Smythies (1957, 1999), Stattersfield & Capper (2000), Thompson (1966), Vowles & Vowles (1997), Wells (2005), Wilkinson, Dutson, Sheldon *et al.* (1991).

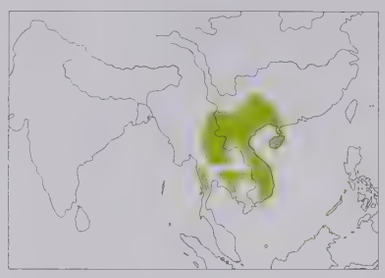
96. White-throated Bulbul

Alophoixus flaveolus

French: Bulbul flavéole **German**: Weißkehl-Haubenbülbül **Spanish**: Bulbul Frentigrís
Other common names: Ashy-fronted (Bearded) Bulbul, Yellow-bellied Bulbul(!)

Taxonomy. *Trichophorus flaveolus* Gould, 1836, Himalayan Mountains = Nepal.
Genus often merged with *Criniger*; recent molecular evidence, however, strongly supports the view that the relationship between the two is remote, despite close similarity in appearance. Putative races described from Assam, in NE India, *viridulus* (Lushai Hills) and *aureolus* (Naga Hills), are considered indistinguishable from nominate. Two subspecies recognized.
Subspecies and Distribution.
A. f. flaveolus (Gould, 1836) – Himalayan foothills from C Nepal E to Bhutan, NE India (Arunachal Pradesh, and S Assam hills including Meghalaya, and Lushai Hills), SE Tibet (in territory claimed by India), NE & SE Bangladesh (Sylhet, Chittagong) and NW & NE Myanmar (Chindwin, Arakan).
A. f. burmanicus (Oates 1889) – S China (W Yunnan), SE Myanmar (Karen Hills, Southern Shan States, Tenasserim) and W Thailand.

Descriptive notes. 21·5–22 cm; male 38–54 g, female 38–48 g. Bulky, brash, conspicuous bulbul with fairly stout bill, adult with spindly, pointed crest (sometimes curved forward), elongated throat feathers often held erect, as if brushed the wrong way. Nominate has bronzy-olive crown and crest, distinctly whitish lores, white-streaked grey ear-coverts, long fine hairs emerging from nape; upperparts bronzy olive, wings and tail rufous-brown; throat white, underparts bright yellow from breast to undertail-coverts; iris brown; bill variable, often mostly pale bluish-grey, particularly at cutting edges and around base; legs silvery grey, pale leaden grey or pale fleshy brown. Sexes similar. Juvenile has browner crest and upperparts, more rufescent wings, distinctly duller yellow (almost brownish) underparts, darker bill. Race *burmanicus* is smaller than nominate, with darker crown; juvenile said to be rather uniform brown with throat whiter, upperparts and wings more rufescent brown than adult, and underparts suffused brown. Voice. Noisy, heard more often than seen. Wide variety of calls, all short and nasal, with no identifiable song. Commonest calls are loud, short, very nasal, strident single hiccup-like "nyak, nyark, nyark" or "nyeek!" notes, repeated at variable rates, often relatively slowly; higher-pitched "yap" when alarmed, often alternately or in chorus by multiple individuals; also noted are shriller, upslurred "shree-shree-shree", and a series of tinny, nasal notes which starts quite slowly and then rises in pitch and accelerates. Most vocalizations similar to those of *A. pallidus* but sharper and higher-pitched.
Habitat. Occurs in understorey or middle storey of primary and secondary evergreen forest, usually at 600–1200 m, rarely up to 1500 m. Some individuals descend to lowlands in winter, when regularly found in more open scrub and bushes, sometimes bordering cultivation.
Food and Feeding. Diet primarily fruit, including berries; recorded as eating gooseberries (*Phyllanthus emlica*) in NE India; also eats insects. Roves in tight-knit parties of 6–15 individuals in winter, creeping and clambering through vegetation in manner of some laughingthrushes (*Garrulax*), following each other closely and flying across gaps in single file. Usually forages within 3 m of ground.
Breeding. Breeds Apr–Jul. Nest reportedly built by both sexes, outer layer constructed of dead leaves and bamboo leaves, fairly loosely fastened together with fine fern rootlets and elastic stems, inner layer also of dead leaves, very strongly bound and lined with fern roots; placed 0–3 m above ground, usually below 1 m, in thick low vegetation (including weeds and brambles) or vine tangle, often near stream. Clutch 3–4 eggs; incubation possibly by both sexes, period 13 days; chicks fed by both parents, no information on nestling period.
Movements. Resident; tends to move downslope in some regions during non-breeding season.
Status and Conservation. Not globally threatened. Generally common throughout range; rare in S China. Very local in Bangladesh, but fairly common at a few sites in Nepal, and very common in suitable habitat in NE India, Bhutan and Myanmar. Able to tolerate considerable degradation and fragmentation of forest. In Nepal occurs in Royal Chitwan National Park, the extreme W locality for the species.
Bibliography. Ali & Ripley (1996), Ali *et al.* (1996), Birand & Pawar (2004), Cheng Tsohsin (1987), Deignan (1956), Dickinson *et al.* (2002b), Grimmett *et al.* (1998), Harvey (1990), Hopwood (1912), Hume (1888), Inglis (1896), Inskipp & Inskipp (1991), Inskipp *et al.* (2000), Koelz (1954), Lekagul & Round (1991), MacKinnon & Phillipps (2000), Mears & Oates (1907), Meyer de Schauensee (1984), Riley (1938), Ripley (1982), Robson (2000), Scully (1879), Singh (1995), Smythies (1986), Stanford & Mayr (1940–1941), Stevens (1914–1915, 1923–1925), Stuart Baker (1892–1893, 1922–1930), Ticehurst (1933).



97. Puff-throated Bulbul

Alophoixus pallidus

French: Bulbul pâle **German**: Blassbauch-Haubenbülbül **Spanish**: Bulbul Pálido
Other common names: Olivaceous (Bearded) Bulbul

Taxonomy. *Criniger pallidus* Swinhoe, 1870, Hainan, China.
Genus often merged with *Criniger*; recent molecular evidence, however, strongly supports the view that the relationship between the two is remote, despite close similarity in appearance. Separation of various races problematical, and listed details provisional; full review necessary in order to establish validity and precise distribution of each. Putative race *grandis* (from Yunnan, in S China) considered indistinguishable from *henrici*. Seven subspecies recognized.
Subspecies and Distribution.
A. p. griseiceps (Hume, 1873) – S Myanmar (Pegu Yomas).
A. p. robinsoni (Ticehurst, 1932) – S Myanmar (Tenasserim).
A. p. henrici (Oustalet, 1896) – S China (S Yunnan E to E Guangxi), N Thailand, N & C Laos and N Vietnam (Tonkin).
A. p. pallidus (Swinhoe, 1870) – Hainan.
A. p. isani (Deignan, 1956) – NE Thailand.
A. p. annamensis (Delacour & Jabouille, 1924) – C Vietnam (N & C Annam).
A. p. khmerensis (Deignan, 1956) – S Laos, Cambodia (except SW) and C Vietnam (C & S Annam).
Descriptive notes. 22–25 cm; 41–52 g. Large, noisy, conspicuous bulbul, crown feathers elongated to form distinct, moderately pointed crest, often raised, elongated throat feathers often puffed out as if combed the wrong way. Nominate race has forehead, crown and nape greyish-brown, lores, cheeks and ear-coverts dusky whitish-grey; upperparts, including lesser wing-coverts, dull olive-green, uppertail-coverts with slight rufescent tinge; tail feathers rufous-brown, outer webs fringed olive-green with rufescent tinge; greater and median wing-coverts brown, slightly rufescent, fringed dull olive-green; flight-feathers pale brown on inner webs, slightly rufescent olive-green on outer webs, most obviously on secondaries and tertials; chin and throat white, breast and belly pale ochraceous yellow, duskier on sides and flanks; vent and undertail-coverts pale ochraceous buff; iris greyish-

On following pages: 98. Ochraceous Bulbul (*Alophoixus ochraceus*); 99. Grey-cheeked Bulbul (*Alophoixus bres*); 100. Yellow-bellied Bulbul (*Alophoixus phaeocephalus*); 101. Yellow-browed Bulbul (*Acritillas indica*); 102. Hook-billed Bulbul (*Setornis criniger*); 103. Hairy-backed Bulbul (*Tricholestes criniger*).

brown to light umber (possibly age-related difference); bill bluish-grey, darker on culmen and tip of upper mandible, paler base and cutting edges; legs pinkish-brown, claws pale horn. Distinguished from *A. flaveolus* by much less yellow underparts, off-white throat, buffier undertail-coverts, duskier head side; from *A. ochraceus* by darker underparts, usually with stronger yellow infusion. Sexes alike. Juvenile resembles adult, but upperparts and underparts slightly paler and brighter, with slight gold suffusion, throat feathers shorter, eyes probably duller. Race *griseiceps* is greener above than nominate, with greyer crown, more whitish-grey lores and ear-coverts, much yellower breast and belly, deeper yellowish buff undertail-coverts; *robinsoni* has duller yellow underparts, duller olive upperparts, less contrast between head and mantle; *henrici* is relatively large, with white throat and pale underparts; *isani* is similar to previous, but differs in having the olivaceous brown of mantle paler and greyer; *annamensis* is also similar, but smaller, with slightly darker, yellower underparts, stronger olive wash on upperparts; *khmerensis* has slightly darker breast and flanks, deeper yellow abdomen, and stronger chestnut tone on upperparts. Voice. Foraging parties give loud scolding calls semi-constantly; no identifiable song. Usual vocalization a harsh, raucous, abrupt "churt churt churt…, chutt-chutt-chutt…", or "chutt-chutt, chik-it chik-it". Also reported to give weak "twee, twee, twee".

Habitat. Broadleaf evergreen forest and open woodland in lowlands and foothills, locally up to 1800 m.

Food and Feeding. Diet mainly berries, although some insects taken; will also take nectar, but much less often than do *Hypsipetes* species. Usually found in middle storey of forests, often in small vociferous groups of 3–6.

Breeding. Breeds Mar–Sept. Observations at one nest suggested that three adults fed young, but whether co-operative breeding is the usual strategy is not known; further study required. Nest a fairly deep neat cup made from dry leaves, lined with fine aerial roots of woody climbers, held together by, and attached to branch at rim with, spider webs and fine, black, hair-like fibres of fungal mycelium; in Thailand placed 1–5 m up in horizontal fork of small branch of sapling or in fallen branch of larger tree. Clutch 2–3 eggs; incubation period 12–13 days; nestling period 10–11 days.

Movements. Apparently resident.

Status and Conservation. Not globally threatened. Very common in S China and Hainan; common in most other parts of its range, including S Myanmar, much of Thailand and N Laos. Seems to tolerate a fair degree of habitat disturbance, and therefore not considered to be at any risk.

Bibliography. 98. Ochraceous Bulbul

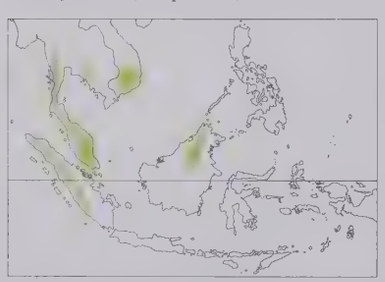
Alophoixus ochraceus



French: Bulbul ocré **German**: Rostbauchbülbül **Spanish**: Bulbul Ocráceo
Other common names: Ochraceous Bearded Bulbul, Brown White-throated Bulbul

Taxonomy. *Criniger ochraceus* F. Moore, 1854, Mergui, Tenasserim, Myanmar.

Genus often merged with *Criniger*; recent molecular evidence, however, strongly supports the view that the relationship between the two is remote, despite close similarity in appearance. If genera thus combined, race name *cabanisi* invalid, as preoccupied, and then replaced by name *sordidus*. Individual recently sighted in NE Cambodia was not racially identified, but probably involved *hallae*. Putative race *crinitus* (described from SW Thailand) considered indistinguishable from nominate. Several other proposed races have been synonymized in the past and are barely distinguishable; thorough review required. Eight subspecies recognized.

Subspecies and Distribution.

A. o. ochraceus (F. Moore, 1854) – SW Thailand and S Myanmar (Tenasserim S of Ye).
A. o. cabanisi (A. Müller, 1882) – S Thailand and C Peninsular Malaysia.
A. o. sacculatus (Robinson, 1915) – S Peninsular Malaysia and Singapore.
A. o. cambodianus (Delacour & Jabouille, 1928) – SE Thailand and SW Cambodia.
A. o. hallae (Deignan, 1956) – S Vietnam (S Annam, Cochinchina).
A. o. sumatranus (R. G. W. Ramsay, 1882) – W Sumatra.
A. o. fowleri (Amadon & Harrisson, 1957) – N Borneo.
A. o. ruficrissus (Sharpe, 1879) – NE Borneo.

Descriptive notes. 19–22 cm; 35–46 g. Bulky, very noisy, conspicuous bulbul with large bill, elongated hindcrown feathers forming crest, typically held half-erect, elongated throat feathers often puffed out, especially when calling. Nominate race has lores and upper face ashy grey or greyish-white, lower face and ear-coverts ashy brown, streaked paler, cap rufous-brown, clearly demarcated against lores; upperparts olive-brown, slightly rufescent on uppertail-coverts; upperwings olive-brown, brighter fringing on flight-feathers; tail dark, chestnut-washed olive-brown, slightly paler on extreme tips; chin and throat whitish, sharply demarcated against face; breast and belly ashy brown (browner at side and flanks) with dull tawny-cream feather edging, sometimes tinged yellowish; undertail-coverts uniform pale tawny; iris rich brown to dull red (variation possibly sex-related); upper mandible dark brown, cutting edges and lower mandible paler greyish-brown or silvery; legs fleshy brown to purplish-brown. Differs from very similar *A. pallidus* in slightly smaller size, shorter crest, duller (browner) and less olive upperparts, no yellow tinge below. Sexes similar, male on average considerably larger than female and may have redder iris. Juvenile has wings and tail more rufescent than adult, iris duller and browner. Race *cabanisi* has slightly more rufous-brown wash on cap, uppertail-coverts and tail than nominate; *sacculatus* is slightly larger and darker than previous, more olive-tinged (less rufous-tinged) brown above, including on cap, with whiter throat, slightly darker ash-grey breast side and flanks; *cambodianus* has duller, less yellowish, upperparts and lighter underparts than last; *hallae* has yellowish-tinged underparts, very like sympatric form of *A. pallidus* (but larger, crest smaller and less erectile, head side less pure grey, paler and slightly less yellow and more buffier-tinged below, slightly paler buff undertail-coverts); *sumatranus* has head, including cap, greyish-brown (lacking rufous tones), throat pure white, underparts darker yellowish-olive, undertail-coverts deep reddish ochraceous; *ruficrissus* has reddish-brown crest and upperparts, brown ear-coverts, dull olivaceous underparts (slightly yellowish on breast), rich reddish-chestnut undertail-coverts; *fowleri* has crest grey with brown tinge, is generally similar to previous but generally greyer on ear-coverts and underparts, less rufous on upperparts and breast. Voice. Variety of loud, grating cackles, similar to those of *A. pallidus*. Commonest calls are raucous, coarse and repetitive, e.g. "chrrt chrrt chrrt chrrt…" or "chik-chik-chik-chik", normally preceded by fluty, nasal "eeyi" and "iiwu" notes; also deep, rich, chuckling phrases with many doubled notes, e.g. "chee-wau, chee-wau, chee-wau", "ti-kwau, ti-kwau, ti-kwau", "chit'it-chit'it-chit'it-chit'it", "chui-wek, chik-wek, chik-wek, chik-wek" and similar. Variable song a deliberate, warbled sequence, e.g. "chip, kerk, ka-duik duik", interspersed with chattering notes; in Borneo, songs said to have terminal emphatic "chee!", followed by variable number of lower steady "chu chu chu" notes. Also gives a series of melodious trisyllabic whistles.

Habitat. Broadleaf evergreen forest, either mature or regenerated back to more or less closed-canopy structure after disturbance; in Borneo, at least, found also in lower-stature, drier forests, and in tall secondary forest with major bamboo component. Level lowlands to slopes, ascending to 1700 m; apparently much higher on Mt Kinabalu (Borneo), where recorded up to 2650 m.

Food and Feeding. Mainly berries and other fruit; also insects. Fruits include *Phyllanthus emblica* and figs (*Ficus*), usually swallowed whole even if more than 1 cm across. In Borneo, diet mainly montane figs in diameter range 3–6 mm, and variety of berries and other fruit, including *Schefflera*, *Gironniera*, *Litsea cubica*, *Callicarpa*, climbing melastomes (*Melastoma*), and berries of introduced elder (*Sambucus nigra*). One record of hornet larvae being eaten, and several reports of aerial sallying to snatch winged termites (Isoptera) in flight; it seems certain that insects form a common dietary supplement. Associates in loose noisy parties of 4–8 individuals, feeding on fruit in trees and shrubs, where it often aggressively displaces smaller bulbuls. Usually found in upper understorey or middle storey, infrequently in canopy.

Breeding. Breeds Feb–Jun. Nest a deep cup-shaped structure suspended by rim from supports, in one instance constructed from twigs and dry leaves, in another from grass blades, its rim reinforced with silk, and lined with black fibres (tentatively identified as horsehair fungal hyphae); few nests described, most placed in sapling or tall bush, sometimes by and over forest path, once 2·5 m above ground in twig fork of lateral branch of sapling, another low down between stems of scrambling ferns. Clutch 2–3 eggs, rarely 4; no information on incubation and fledging periods; fledglings tended by both pair-members.

Movements. Resident.

Status and Conservation. Not globally threatened. Locally common throughout range; considered extremely common in S Myanmar and common in Borneo. Recent sighting (Jan 2002) in NE Cambodia possibly indicative of range extension. Although relatively reliant on mature forest, this species is not thought to be at any risk because it ascends slopes to fairly high altitudes where habitat more secure, and because it tolerates fairly extreme habitat fragmentation, surviving in rather small islands of forest. Occurs in a range of protected areas, including Nam Bai Cat Tien National Park, in Vietnam, Khao Yai National Park, in Thailand, Taman Negara National Park, in Peninsular Malaysia, and Mount Kinabalu National Park, in Borneo (Sabah).

Bibliography. 99. Grey-cheeked Bulbul

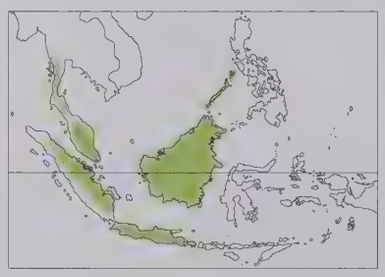
Alophoixus bres



French: Bulbul brès **German**: Grauwangenbülbül **Spanish**: Bulbul Bres
Other common names: Grey-cheeked Bearded Bulbul, Olive White-throated Bulbul; Scrub Bulbul (nominate)

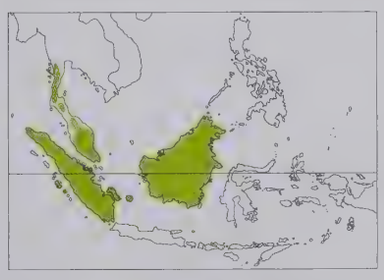
Taxonomy. *Lanius Bres* Lesson, 1831, Bogor, Java.

Genus often merged with *Criniger*; recent molecular evidence, however, strongly supports the view that the relationship between the two is remote, despite close similarity in appearance. Proposed taxon *bartelsi* (from Java) is a synonym of nominate. Putative race *balicus* (E Java, Bali) said to have browner ear-coverts than W Javan birds, but this feature also present on many specimens from latter region; better considered, therefore, a synonym of nominate. Four subspecies currently recognized.

Subspecies and Distribution.

A. b. tephrogenys (Jardine & Selby, 1833) – S Myanmar (Tenasserim S of c. 14° N), S Thailand, Peninsular Malaysia (not Singapore) and E Sumatra.
A. b. bres (Lesson, 1831) – Java and Bali.
A. b. gutturalis (Bonaparte, 1850) – Borneo.
A. b. frater (Sharpe, 1877) – W Philippines (Calamians, Palawan, Balabac).

Descriptive notes. 21·5–23 cm; 29–44 g, male 41–46 g and female 51–52 g (*gutturalis*). Bulky, very noisy, conspicuous bulbul with erectile hindcrown crest, throat feathers usually puffed out, especially when calling. Nominate race has lores and upper face mid-grey, shading more ash-grey to brown on ear-coverts; rest of cap dark rufescent olive-brown; upperparts from mantle to rump brownish-olive, uppertail-coverts brownish-chestnut, lighter and brighter than cap; upperwings brownish-olive, tertials and inner secondaries tinged slightly more rufous, flight-feathers fringed bright rufescent on outer webs; tail uniform chestnut-brown; chin and throat white; breast strongly washed with dark olive; upper flanks pale olive-brown, suffused with yellow, lower underparts creamy yellow, undertail-coverts washed ochraceous buff; iris brown to rich brownish-red (variation possibly related to age or sex); upper mandible dark plumbeous brown, lower mandible and cutting edges blue-grey; legs yellowish-pink to pinkish-brown, claws dusky flesh. Differs from *A. flaveolus* in darker grey head side;



from *A. ochraceus* in shorter and less prominent crest, yellower belly. Sexes similar. Juvenile is very like adult, but wings more rufescent, head side tinged brown, iris duller brown. Race *tephrogenys* has light ash-brown wash on breast (broad pale yellow edging giving mottled effect), pale amber-yellow belly; *gutturalis* is dirtier brown above, least yellow below; *frater* is similar but slightly more greenish on mantle. Voice. Very variable. Seems to vocalize semi-constantly, producing wide range of melodious whistles. Song of clear, well-structured, ringing, mournful phrases, variously as "whi'u wiu iwi", "you yuwi", "cheeru cheeu cheeriu", "prii chiu chew chew" and similar, often followed by higher-pitched discordant notes (e.g. "iiu"); in Philippines (race *frater*), one song variant transcribed as "chip-pu chu-chu-chu-chu cha-wheeet"; throughout range, song phrases usually interspersed with harsh scolding notes or rattled "trrit" notes. Also gives muted "chirret".
Habitat. Mature broadleaf evergreen and mixed deciduous forest, also edges, overgrown plantations of exotic species; also second growth having layered, more or less closed-canopy structure, and where young regrowth stands alongside primary forest. At Pasoh research forest, in Negeri Sembilan (Peninsular Malaysia), one third more individuals trapped in mature forest than in 20-year regenerating forest, suggesting preference for former. Lowlands up to 1150 m, rarely to 1500 m; S of lowland range of *A. ochraceus* in Peninsular Malaysia, the commonest *Alophoixus* of submontane slopes.
Food and Feeding. A generalist, eating large amounts of both fruit and invertebrates. Various shade-layer fruits taken, including *Eurycoma longifolia*, also figs (*Ficus*) e.g. banyans, and nine of 25 *Ficus* species (mean minimum diameter in range 5·4–15·5 mm) in study at Kerau, in Peninsular Malaysia. In Java, recorded as eating a variety of insects, including beetles (Coleoptera), bugs (Hemiptera, including homopterans), dragonflies and damselflies (Odonata) and termites (Isoptera); stomachs of specimens from Sumatra contained insects, including a cicada (Cicadidae). Usually forages singly, in pairs or in small groups; no groups that may exceed potential family size reported. Gathers at fruiting shrubs and trees in lower and middle storeys. Often joins (or forms nucleus of) roving mixed-species flocks, suggesting that animal prey is an important component of intake; of 38 individuals encountered in one study at Gombak, in Malaysia, 14 (37%) were attending flocks. Fruit probably harvested opportunistically while travelling with mixed flocks. Visits forest streams and pools to drink. Apparently maintains fairly limited feeding territories, but this yet to be investigated directly.
Breeding. Breeds Apr–Jul in N Thailand, Jan–Jul in Peninsular Malaysia, in almost all months in W & C Java, and Apr–Jun in Philippines. Nest a standard cup-shaped structure placed in low vegetation; clutch usually 2 eggs. No other information.
Movements. Resident; appears unusually territorial for a bulbul.
Status and Conservation. Not globally threatened. Sometimes uncommon, but usually common to very common throughout much of range, including Greater Sundas (Sumatra, Java, Borneo). Its tolerance of degraded and submontane habitats suggests that it is not at any immediate risk.
Bibliography. Becking (1989), Chasen & Hoogerwerf (1941), Collin & Hartert (1927), Danielsen & Heegaard (1995), Davison (1987, 1997a), Deignan (1945, 1956), Dickinson & Dekker (2002b), Dickinson, Dekker *et al.* (2002b), Dickinson, Kennedy & Parkes (1991), Duckworth & Kelsh (1998), duPont (1971), Fogden (1972), Gibson-Hill (1949), Gregory-Smith (1997a), Hellebrekers & Hoogerwerf (1967), Holmes (1996), Hoogerwerf (1949b), Jenkins *et al.* (1996), Jeyarajasingam & Pearson (1999), Kennedy *et al.* (2000), Lambert (1989b), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Mayr (1938), McClure (1967), Medway & Wells (1976), Mees (1996), Mitra & Sheldon (1993), Riley (1938), Robson (2000), Round & Brockelman (1998), Smythies (1957, 1986, 1999), Stresemann (1913), Ticehurst (1933), Tweeddale (1878a), Wells (2005), Wong (1985).

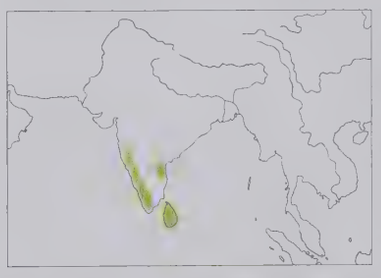
100. **Yellow-bellied Bulbul**

Alophoixus phaeocephalus

French: Bulbul à calotte grise **German**: Schwefelbülbül **Spanish**: Bulbul Capirotado
Other common names: Grey-headed (Bearded) Bulbul, Crestless White-throated Bulbul

Taxonomy. *Ixos* (*Trichixos*, Less.) *phaeocephalus* Hartlaub, 1844, Melaka, Peninsular Malaysia.
Genus often merged with *Criniger*; recent molecular evidence, however, strongly supports the view that the relationship between the two is remote, despite close similarity in appearance. DNA analysis suggests that present species is not close to other members of genus, and that it should possibly be separated in a monotypic genus. Delimitation of races in Borneo complex, variation appearing clinal, and perhaps only extremes worthy of recognition; listed ranges indicate evident ranges where known, but species probably present throughout; further study required. Three putative races (*caniceps*, *rufocaudatus*, *cantori*) merged with nominate; *medius* (described from Long Petah, in E Borneo) considered indistinguishable from *sulphuratus*. Four subspecies recognized.
Subspecies and Distribution.
A. p. phaeocephalus (Hartlaub, 1844) – extreme S Myanmar (extreme S Tenasserim), S Thailand, Peninsular Malaysia, and Sumatra (including Bangka, Belitung, Siberut and Sipura).
A. p. connectens Chasen & Kloss, 1929 – NE Borneo.
A. p. sulphuratus (Bonaparte, 1850) – C Borneo (E Sarawak and W Sabah S to SE Kalimantan).
A. p. diardi (Finsch, 1867) – W Borneo (S from R Baram).

Descriptive notes. 20–20·5 cm; 23–38 g. Large, brightly coloured, relatively retiring bulbul, eyes contrasting sharply with pale face, elongated chin and throat often puffed out and sharply demarcated. Nominate race has lores whitish, rest of face to gape and ear-coverts pale blue-grey; cap to neck darker blue-grey, slaty feather bases showing (producing squamate appearance in fresh plumage); upperparts from mantle to rump dark brown-olive with greenish tinge; rear edge of rump, and long overlying back plumes, pale olive-yellow, uppertail-coverts chestnut; upperwing dark olive-brown with slight rufescent tinge, tertials and fringes of flight-feathers warm rufous-olive; tail uniformly chestnut-tinged olive; chin and throat white, sharply demarcated against grey of face; side of breast and upper margin of flanks olive-green with yellowish cast, rest of underparts bright canary-yellow; iris clear brown to rich red-brown; upper mandible dark horn, lower mandible and cutting edges of upper mandible blue-grey or pale plumbeous; legs pale fleshy brown or yellowish-pink. Sexes similar. Juvenile has iris light brown, culmen and tip of upper mandible horn-brown. Race *diardi* has conspicuous yellow tip of tail; *connectens* has buffy wash on throat, an almost complete breastband, and lacks yellow tail tip; *sulphuratus* appears to be a variable intermediate between previous two races. Voice. Calls with subdued harsh, slightly buzzy "whi'ee whi'ee whi'ee", or (presumably same) a rasping "cherrit-berrit", and variety of other grating notes, often given when scolding human observers. Sometimes a loud "chack", especially in flight.
Habitat. Broadleaf evergreen forest, well-developed secondary growth (having relatively closed canopy, and layered structure), mature or overgrown tree plantations adjacent to forest, also transition zone between forest and coastal vegetation. At Pasoh research forest, in Negeri Sembilan (Peninsular Malaysia), 60% more individuals trapped in mature forest than in 20-year regenerating habitat, suggesting preference for former. Also enters peatswamp-forest and kerangas forest, and sometimes seems to prefer these habitats; of four members of genus at Gunung Mulu National Park, in Borneo (Sarawak), this was the only one to thrive in peatswamp-forest. Lowlands to 1000 m; not recorded above 760 m in Peninsular Malaysia.
Food and Feeding. A generalist, eating both fruit and insects. At Kerau, in Peninsular Malaysia, parties visiting fig (*Ficus*) crops took fruit of eleven of 25 fig species (in fruit-diameter range 5·4–15·5 mm); even while in these trees, however, tended to take more insects than fruit, and may have stopped off only while moving through. Less accessible fruit, e.g. berries of *Vitex pubescens*, taken by snatching during brief hovers. Individuals noted as catching bright green beetles (Coleoptera), but major insect component of diet unstudied. Usually encountered singly, in pairs, or in small parties of 3–4 (rarely five) individuals; rarely, if ever, in groups of 6–10 (unlike several congeners). Joins other bulbuls at fruiting shrubs; accompanies mixed-species flocks of insectivores, mostly other members of genus and various babblers (Timaliidae), in understorey. Frequents lower storey, generally lower down than most congeners. Regularly drops from lower branches to the ground, but usually returns to a perch within few seconds.
Breeding. Breeds Apr–Aug. Rate of retrapping in lowland forest in Peninsular Malaysia suggests that pair probably territorial. Clutch 2 eggs. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally fairly common to common throughout much of range. Extinct in Singapore for at least five decades, following deforestation. In mature lowland-forest understorey at Pasoh, in Negeri Sembilan (Peninsular Malaysia), long-term mist-netting showed this to be the second most frequently caught resident passerine, after Short-tailed Babbler (*Malacocincla malacensis*); at least 20–23 individuals made regular use of the 15-ha study plot during two successive breeding seasons, suggesting high population density. Given this abundance in relatively small patches of forest, and the species' use of submontane forest on slopes, this pycnonotid is unlikely to become at risk in immediate future.
Bibliography. Chasen & Hoogerwerf (1941), Danielsen & Heegaard (1995), Davison (1987), Davison & Chew Yen Fook (1996), Dickinson *et al.* (2002b), Duckworth & Kelsh (1998), Eyton (1845), Fogden (1972), Ford & Davison (1995), Gibson-Hill (1949), Gregory-Smith (1997a), Holmes (1994), Horsfield & Moore (1854), Hume & Davison (1878), Jenkins *et al.* (1996), Jeyarajasingam & Pearson (1999), Kloss (1930), Lafresnaye (1845), Lambert (1989b, 1992), Lekagul & Round (1991), Lim Kim Seng (1992), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Mayr (1938), Medway & Wells (1976), Mees (1986), Nash & Nash (1988), Riley (1938), Robson (2000), Smythies (1957, 1986, 1999), Vowles & Vowles (1997), Wells (2005), Wells *et al.* (1978), Wong (1985).



Genus *ACRITILLAS* Oberholser, 1905

101. **Yellow-browed Bulbul**

Acritillas indica

French: Bulbul à sourcils d'or **German**: Goldbrauenbülbül **Spanish**: Bulbul Cejiamarillo
Other common names: Golden-browed Bulbul

Taxonomy. *T[richophorus]. Indicus* Jerdon, 1839, Nilgiri District, India.
Sometimes placed in genus *Hypsipetes* or *Iole*, but unique morphology and nest structure support treatment in monotypic genus. Races poorly differentiated, thought possibly to be based on age-related differences, and species sometimes considered monotypic; thorough review is necessary. Putative race *intensior* (from Kunjapani, in Tamil Nadu) considered indistinguishable from nominate, and synonymized with it. Three subspecies tentatively recognized.
Subspecies and Distribution.
A. i. icterica (Strickland, 1844) – Western Ghats (C Maharashtra S to Kerala) and Eastern Ghats (Andhra Pradesh and Tamil Nadu), in peninsular India.
A. i. indica (Jerdon, 1839) – SW India and Sri Lanka (except SW).
A. i. guglielmi (Ripley, 1946) – SW Sri Lanka.

Descriptive notes. 20 cm; 27–34 g. A trim, brightly coloured bulbul with prominent large dark eyes, slightly decurved bill. Nominate race has brow, orbital region, face and throat bright pure yellow, ear-coverts olive-green with some yellow streaking; crown and upperparts olive-green with bronzy tinge, slightly brighter green on wings and tail; inner webs of flight-feathers brown (yellow at base), inner webs of rectrices yellowish; wholly yellow below, creating distinct two-tone appearance; iris light reddish or dark red (Sri Lanka); bill black; legs black, slaty or bluish-grey. Female is apparently slightly duller than male, and duskier on face. Juvenile is duller and more olive-yellow than adult, cheeks faintly barred brownish and flanks more dusky, chin, throat and belly yellowish-white, breast greyish-yellow; wings and mantle infused with rufescent tinge. Race *icterica* is allegedly paler, duller, less yellowish on upperparts and side of head than nominate; *guglielmi* is greener overall than previous, less bronzy yellow on upperparts, yellow underparts tinged with green (rather than bronzy-tinged bright yellow). Voice. Cheery, varied, and near-continuous whistles. Songs include brief, bright, loud, rollicking warble of unslurred ringing notes of variable form, sometimes ending distinctly higher with a few chiming notes, sometimes including a few dry purring trills. Calls include clear, sweet, querying "wheep", often doubled, and sometimes almost disyllabic ("t-wheep"); also frequently gives less inflected, more subdued, nasal version, "nyek-nyek", and less often a harsh jarring "chaink chaink" in alarm.
Habitat. Sholas, evergreen forest edge, secondary forest, shade coffee plantations, undergrowth and occasionally gardens, tending to be confined to more humid areas. In parts of Sri Lanka (Uva) tolerates highly degraded habitat, occurring in small patches of low forest along streams in otherwise cultivated country. Low hills to 2000 m (optimum c. 1000–1500 m), sometimes down to near sea-level.

Food and Feeding. Mostly fruit and seeds; also many invertebrates, including spiders (Araneae) and variety of winged insects. Noted as eating flowers and flower buds of *Apama siliquosa* and *Cullenia exarillata*. Rather unobtrusive and retiring. Travels in pairs and small flocks in lower and middle storeys; monospecific flocks of up to 60 individuals reported in Sri Lanka. Often accompanies mixed-species flocks, regularly forming their nucleus. Winged insects usually taken from lateral branches and in tops of saplings, or snatched in short fluttering aerial sallies. Fruit and seeds often plucked in brief hovering flights.
Breeding. Breeds chiefly Jan–May, sometimes extending to Sept; mostly Apr–May in Sri Lanka. The fact that small parties are sometimes accompanied by young suggests possibility of some form of co-operative breeding. Nest made of grass, dead leaves and moss, bound with cobweb and lined with rootlets; some were outwardly composed of rope-like fibre, and bound in spider webs and the silk of weaver ants (*Oecophylla smaragdina*), incorporating some dead leaves as camouflage, and lined internally with pieces of fine grass; often as flimsy hammock slung in horizontal fork (usually 1·5–4·5 m up) in sapling or shrub, at other times lodged in upright fork as nests of most pycnonotids, often poorly concealed. Clutch 2–3 eggs; no information on incubation and nestling periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Often common or very common throughout Western Ghats and Sri Lanka, wherever suitable wooded habitat exists. Fairly common as far N as Mahabaleshwar; abundant in Goa, where described as "by far the most common bird" in foothill forests. Rare in Eastern Ghats, but recently recorded N to Nalamalla Hills. Tolerates wide variety of forest types, and therefore seems unlikely to become threatened. Occurs in a range of protected areas, including Silent Valley and Periyar National Parks, in India, and Hakgala Strict Nature Reserve and Peak Wilderness Sanctuary, in Sri Lanka.

Genus *SETORNIS* Lesson, 1839

102. **Hook-billed Bulbul**

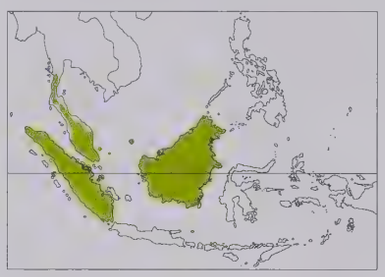
Setornis criniger

French: Bulbul à long bec **German**: Langschnabelbülbül **Spanish**: Bulbul Piquilargo
Other common names: Long-billed Bulbul(!)

Taxonomy. *Setornis criniger* Lesson, 1839, Sumatra.
Monotypic.
Distribution. Sumatra, Bangka and Borneo.

Descriptive notes. 20 cm. Chunky, crestless, relatively unobtrusive bulbul with distinctive face pattern, strong and distinctly hooked long bill, long, slightly rounded tail. Has whitish supercilium, black eyestripe and malar stripe, pale grey-brown ear-coverts; rich brown above, darkest on crown, tail and wings; very long hair-like feathers protrude from nape; tail conspicuously tipped white on inner webs of outer feathers; chin, throat and underparts white, washed buffy on mid-belly and distinctly solid grey on flanks; iris dark brown; bill black; legs black. Sexes alike. Juvenile undescribed. VOICE. Harsh "carrrk" reported; also harsh, but not loud, "chow, cho, cho". Often quiet, but family groups in S Kalimantan (Borneo) were "noisy and frequently heard".
Habitat. Generally considered a specialist of stunted forest types, such as kerangas or peatswamp. In Borneo, also found (at least in C Kalimantan) in lowland dipterocarp forest and (elsewhere) in abandoned rubber (*Hevea*) plantations; near Gunung Mulu, occupies ecotones between *Shorea albida* forest and peatswamp or kerangas. Lowlands; in Borneo, occurs close to coast in Sarawak and Kalimantan, with occasional records in Kalimantan up to 1000 m in stunted ridgetop forest; unconfirmed report from 1500 m.
Food and Feeding. Fruit, including small pulpy berries. Also reported as feeding on small beetles (Coleoptera), dragonflies and their nymphs (Odonata), ants (Hymenoptera) and spiders (Araneae); bill design, somewhat like that of an antshrike (Thamnophilidae) suggests high quantity of invertebrates in diet. Generally found in pairs or in small parties; up to seven seen together. Forages in middle storey and lower growth; snatches prey items from cobwebs.
Breeding. In Borneo, individual carrying food in Aug (Sarawak) and newly fledged young trapped in May (S Kalimantan). Display seen in Sept, involved bird lowering its head and shivering its outstretched wings. No other information.
Movements. Resident.
Status and Conservation. VULNERABLE. Locally fairly common in Borneo, but scarce in Sumatra; patchily distributed throughout. Massive rates of deforestation and forest fires have reduced total area of peatswamp and kerangas which make up this species' favoured habitat. In Borneo, it is fairly common in Tanjung Puting National Park (Kalimantan), but generally scarce in most protected areas, including Danum Valley (Sabah), Gunung Mulu and Similajau National Parks (Sarawak), and Gunung Palung National Park (Kalimantan). Continued protection of all reserves in which it is present is essential, as is a higher profile for the conservation of peatswamp-forest and kerangas forests in the Sundaic region. Given the paucity of distributional information relating to this species, further surveys should attempt to clarify its status and distribution in more remote regions of Sumatra and Borneo.

Butchart & Stattersfield (2004), Collar *et al.* (2001), Dickinson *et al.* (2002b), Duckworth & Kelsh (1998), Duckworth *et al.* (1996), Dutson (1990), Dutson *et al.* (1991), Holmes (1996), Hose (1893), Laman *et al.* (1996), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Mees (1986), Nash & Nash (1988), Pfeffer (1960–1961), Sheldon (1987), Smythies (1957, 1999), Stattersfield & Capper (2000), Vowles & Vowles (1997), Wilkinson, Dutson & Sheldon (1991), Wilkinson, Dutson, Sheldon *et al.* (1991).



Genus *TRICHOLESTES* Salvadori, 1874

103. **Hairy-backed Bulbul**

Tricholestes criniger

French: Bulbul chevelu **German**: Borstenmantelbülbül **Spanish**: Bulbul Peludo

Taxonomy. *Br[achypodius]*. ? *criniger* Blyth, 1845, Melaka, Peninsular Malaysia.
Often placed in an expanded genus *Hypsipetes*, but unique features favour placement in monotypic genus. Substantial overlap in characters among all three races suggests that treatment as a variable monotypic species may be better; full review required. Described races *minutus*, *xanthogenys* and *fulvicauda* are synonyms of nominate. Three subspecies recognized.
Subspecies and Distribution.
T. c. criniger (Blyth, 1845) – extreme S Myanmar (Tenasserim S of 11°30' N), S Thailand (S of 13° N), Peninsular Malaysia (including Tioman Is) and E Sumatra.
T. c. sericeus Robinson & Kloss, 1924 – W Sumatra (including Musala I and Batu Is) and Lingga Archipelago.
T. c. viridis (Bonaparte, 1854) – Borneo and N Natuna Is.

Descriptive notes. 16–17 cm; 12–21 g. Small, unassuming, relatively quiet bulbul, olive above, yellowish below, with slightly rounded tail, strong rictal bristles, small and weak legs and feet. Has distinctive pale yellowish lores and broad area surrounding eye; ear-coverts pale dull yellow, longest feathers becoming brownish-olive at tips; feathering at base of lower mandible and under ear-coverts mixed with greyish-white and pale yellow, sometimes more distinctly greyish; cap and neck dark rufescent olive-brown, mantle to rump olive-brown, hair-like filoplumes (up to 50 mm long) extend from nape and mantle over back (rarely visible in field); uppertail-coverts olive-rufous, clearly demarcated; upperwings olive-rufous, especially rufescent on tertials, inner secondaries and outer margin of primaries; tail bright rufous-brown, tips of lateral rectrices creamy white (showing as distinct pale tips from below); chin and throat creamy white (greyish feather bases showing through faintly), merging into yellow of mid-breast; breast side pale grey, mottled dirty greyish-olive, or vague mottling across whole breast; upper flanks olive, lower flanks and belly to undertail-coverts yellow; iris dark brown or pale umber; bill light blue-grey, culmen ridge and tip of upper mandible black or horn-brown (difference possibly age-related); legs pale greenish-brown or fleshy brown, claws horn-brown. Sexes alike, female on average smaller than male than male. Juvenile has iris grey to grey-brown, legs, feet and claws pale fleshy pink. Race *sericeus* is larger than nominate, with duller yellow undertail-coverts; *viridis* is similar, but brighter on upperparts. VOICE. Presumed song a series of scratchy, chattering, warbled phrases interspersed with quavering "whirrrh"; in Peninsular Malaysia, same song described as a quiet, stuttering little phrase, "tutti tulip tikker tu". Also utters long, fairly high-pitched, soft, husky, rising whistle, "whiiiii" or "chui-i", repeated at fairly long intervals; sharp, chattering scolds, including "pree-chu, preeu-chu" and "pree-chuchu", given by flock when mobbing human observer.
Habitat. Evergreen forests, either mature or regenerated back to a more or less closed-canopy condition; also peatswamp-forest and well-structured secondary forest, sometimes where bamboo dominates. From lowlands to 1000 m.
Food and Feeding. A generalist, feeding on fruit and arthropods. Animal items include caterpillars, beetles (Coleoptera), small orthopterans and mantids; apparently takes greater amount of insects than do most bulbuls. At Kerau, in Peninsular Malaysia, small parties visited five of 25 *Ficus* species studied, taking mainly insects attracted to the crop but also some of the fruit (in mean small-diameter range 5·4–11·6 mm). In Borneo, seen to eat berries of *Macaranga* and *Trema orientalis*. Usually encountered in lower storey or middle storey of forest, sometimes singly, more often as pairs; occasionally a small (potentially family-sized) group, with no record of more than five individuals together. Frequently joins mixed-species foraging flocks; in one study at Gombak (Peninsular Malaysia), more than half (68%) of all individuals observed were attending such flocks. Generally hunts more like a babbler (Timaliidae) than a bulbul, actively inspecting foliage and branches for arthropods. Takes small caterpillars and arthropods from foliage; flying insects caught on the wing during agile sallies. Never descends to ground. At Kerau, most fruit was cropped from perches, some in fly-past snatches; foragers showed morning and evening peaks of activity. Seems more than usually inquisitive; often approaches or follows human observers, sometimes mobbing them.
Breeding. Season Feb–Aug. No other information.
Movements. Resident. Long-term mist-netting in Selangor and Negeri Sembilan (Peninsular Malaysia) revealed altitudinal difference in rates of retrapping of marked individuals (24% in slope forests; 40–46% in lowland forests), implying higher density/proportion of sedentary individuals in lowlands. At Pasoh (Peninsular Malaysia), this was one of few species showing no significant difference in totals handled and retrapping rates between equivalent-sized (15–17 ha) plots of mature versus 20-year-old regenerating forest, but during breeding seasons almost twice as many individuals made repeated to regular use of regenerating plot. Repeated recapture within and between breeding seasons implies faithfulness to fixed activity space, suggesting that this is defended as a territory (but active territoriality not confirmed). Some local movements occur: in Selangor (Peninsular Malaysia), two ringed birds moved 3–5 km between captures, one of them in the space of 24 hours.
Status and Conservation. Not globally threatened. Generally common. Occurs in a range of mature forest types, and able to withstand fairly drastic fragmentation of habitat. This resilience, and the species' use of submontane slopes, suggest no immediate threat to its survival. Ongoing catastrophic clearance of lowland Sundaic forests, however, implies that overall numbers have declined dramatically, and this situation requires monitoring. Occurs in a range of protected areas, including Taman Negara National Park, in Peninsular Malaysia. An apparently isolated population at N limit of its range falls within Kaeng Krachan National Park, in Thailand.

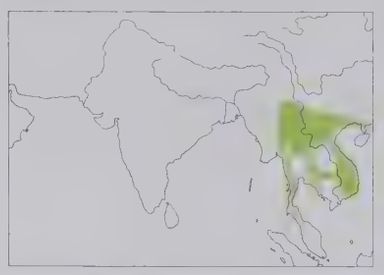
Genus *IOLE* Blyth 1844

104. Olive Bulbul

Iole virescens

French: Bulbul olive **German**: Burmabülbül **Spanish**: Bulbul Verdoso
Other common names: Blyth's Olive/Viridescent Bulbul

Taxonomy. *I[ole]. virescens* Blyth, 1845, Arakan, Myanmar.
Often placed in expanded genus *Hypsipetes*; when thus treated, current species name invalid, as preoccupied, and replaced by new name *viridescens*. Taxonomic status, morphological characters and vocalizations of populations in NE India and Myanmar uncertain or confusing, and possibly more than one species involved; birds in Bangladesh apparently belong to race *cacharensis*, but further study needed. Three subspecies recognized.
Subspecies and Distribution.
I. v. cacharensis (Deignan, 1948) – NE India (S Assam hills, extreme W Manipur, and Meghalaya) and SE Bangladesh (Chittagong).
I. v. myitkyinensis (Deignan, 1948) – W & E Myanmar.
I. v. virescens Blyth, 1845 – SW & S Myanmar (including Arakan) and SW Thailand.



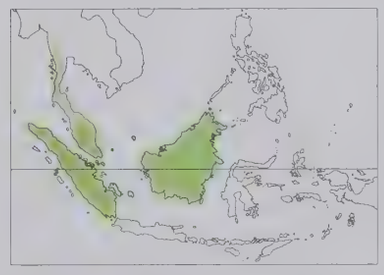
Descriptive notes. 19 cm. A small, drab bulbul. Nominate race has side of head yellowish-olive; ear-coverts generally appear paler than crown; crown and upperparts strongly tinged olive, underparts unstreaked olive-yellow; iris reddish, brownish or greyish-pink (whitish-grey to grey eyes reported from W Myanmar); upper mandible brownish-horn, lower mandible paler (slightly bluish around gape); legs brownish-pink. Distinguished from very similar *I. propinqua* mainly by more olive tone above, stronger yellow tinge below, darker eyes. Sexes alike. Juvenile is rustier on upperparts (including wing and tail), with paler undertail-coverts. Race *cacharensis* is smaller and nearly uniform bronzy olive above, duller olive below with bright yellow on central throat and belly, slight cinnamon tinge on undertail-coverts, birds from Chittagong (apparently this race) have rufescent crown (slightly crested) and tail, somewhat paler and greyer face and underparts, yellowish throat and centre of belly, vent tinged buff; *myitkyinensis* has reduced yellow on underparts (possibly morphologically indistinguishable from some *I. propinqua*). Voice. In Thailand (nominate race), a common call, given fairly persistently, is strongly upslurred, strident, mewing "whee-ík", similar to that of *I. olivacea*, less nasal than primary call of *I. propinqua*; voice of *cacharensis* and *myitkyinensis* undocumented.
Habitat. Moist broadleaf evergreen forest, semi-evergreen forest and tall secondary growth (e.g. in abandoned cultivation), often with dense shrub layer or dense growth of vines. In Meghalaya, in India, reported to occur (at least historically) in well-wooded ravines. Lowlands to 1000 m, most often in foothills.
Food and Feeding. Feeds mainly on berries, sometimes insects. Usually in pairs or small (family?) parties; reports of flocks of over 100 individuals require verification. Forages in middle storey, tops of trees, and high bushes; tends to be rather shy and unobtrusive.
Breeding. Feb–Sept, mainly Mar–Jun, varying locally. Only information on nest is from old records from N India (identification possibly suspect); compact and cup-shaped structure, built with strips of inner bark, scraps of outer bark and fine twigs, lined with black fern roots and long fibres, usually a few dead leaves attached to outside with cobwebs, suspended between horizontal twigs or in vertical fork c. 1·5 m up, and poorly concealed, in bush or low tree inside dense forest. Clutch apparently 3 eggs. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Mostly very local, but probably overlooked. In India, apparently rare in Khasi Hills and Garo Hills of Meghalaya, mostly at their fringes; very local in Manipur according to historical literature, but "rather common" in the "Jhiri level". In Bangladesh, evidently common on basis of old specimen records from Chittagong, but scarce in Sylhet. Generally poorly known in Myanmar; occurs in Chindwin Valley, first record for upper Chindwin (near Kalewa) in 1995. In Thailand confined to W forests, where locally fairly common.
Bibliography. Ali & Ripley (1996), Bingham (1903), Deignan (1948a), Dickinson & Dekker (2002b), Dickinson *et al.* (2002b), Gregory (2000), Grimmett *et al.* (1998), Harvey (1990), Hume (1888), Hume & Davison (1878), Lekagul & Round (1991), Mears & Oates (1907), Ripley (1982), Rippon (1901), Robson (1995, 2000), Smythies (1986), Stuart Baker (1892–1893, 1922–1930), Ticehurst (1933).

105. Grey-eyed Bulbul

Iole propinqua

French: Bulbul aux yeux gris **German**: Grauaugenbülbül **Spanish**: Bulbul Ojigrís

Taxonomy. *Criniger propinquus* Oustalet, 1903, Pa Mou, Tonkin, north Vietnam.
Often placed in expanded genus *Hypsipetes*. All races are extremely similar and probably represent points on steep clines; subspecific allocation probably requires simplification, and full review is necessary. Proposed race *lönnbergi* (described from Pang Huai Hom and Khao Phlung, in Thailand) is a synonym of nominate. Six subspecies currently recognized.
Subspecies and Distribution.
I. p. propinqua (Oustalet, 1903) – S China (S Yunnan), E Myanmar, N Thailand and N Laos.
I. p. aquilonis (Deignan, 1948) – N Vietnam and S China (S Guangxi).
I. p. simulator (Deignan, 1948) – SE Thailand, Cambodia, S Laos and S Vietnam (S Annam).
I. p. innectens (Deignan, 1948) – S Vietnam (Cochinchina).
I. p. lekhakuni (Deignan, 1954) – S Myanmar (N Tenasserim) and W Thailand (including Kanchanaburi).
I. p. cinnamomeoventris Stuart Baker, 1917 – S Myanmar (S Tenasserim), peninsular Thailand and extreme N Peninsular Malaysia.



Descriptive notes. 17–19 cm; 26 g. Relatively slim, dull, small-headed bulbul crown feathers often raised in slightly frizzy crest. Nominate race has crown to hindneck dull olive-rufous, lores to above eye, upper face and ear-coverts smoky grey; mantle to rump olive-brown, uppertail-coverts dark rufous-brown; upperwing olive-brown, fringed brighter olive on outer secondaries and primaries, slight bronzy sheen on tertials and inner secondaries; tail uniform dark rufous-brown; chin and throat dull white, feathers slightly elongated; mid-breast off-white with dirty yellowish fringing, breast side and flanks ashy olive-brown (forming distinct patch); belly cream, tinged olive-brown, undertail-coverts uniform tawny-brown (tone and pattern slightly variable); iris clear grey to white, contrasting blackish eyelid rim; upper mandible blackish-brown, lower mandible pale bluish-grey; legs fleshy brown to purplish-brown. Sexes alike. Juvenile is generally duller than adult, with light brown iris. Race *aquilonis* is yellower below (particularly mid-belly) than nominate, thus more similar to race *myitkyinensis* of *I. virescens* (ranges do not overlap); *simulator* is less green above and much less yellow below (best distinguished from similar *I. olivacea* by more rufescent undertail-coverts, more olive wings, yellowish-tinged underparts, greyer supercilium); *innectens* has relatively dark olive-green upperparts; *lekhakuni* differs from nominate in brownish-olive (not olive-green) upperparts, greyer underparts; *cinnamomeoventris* lacks yellow tones below, these replaced by buffy clay-coloured suffusion strongest on undertail-coverts. Voice. No complex song described. Distinctive loud, flat, very nasal "uuu-wit" or "berret", second note stressed but not upwardly inflected; in Cochinchina (race *innectens*) a slightly different "whii-it" and flatter "wowh", or "weeao"; in S Thailand (*cinnamomeoventris*) a much less nasal "prrrit". Also gives occasional soft whistled note. Less noisy than *Alophoixus* species.
Habitat. Broadleaf evergreen and mixed deciduous forest and edges; also tolerates (or even prefers) secondary forest and disturbed vegetation, often with major bamboo or vine component, especially around clearings and along roads, tracks and rivers through forest. Lowlands to 1000 m, rarely to 1500 m.
Food and Feeding. No detailed information on diet; mainly fruit and insects. Usually solitary or in pairs, but sometimes in groups at fruiting shrubs and trees. Forages in canopy and middle storey; not descending to ground. Relatively shy and unobtrusive.
Breeding. Apr in N Thailand. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Locally fairly common, but probably often overlooked owing to identification problems. Apparently scarce in S Thailand; probably not common in S China. Considering its ability to survive in highly degraded or regenerating habitats, it is probably generally secure.
Bibliography. Cheng Tsohsin (1987), Daltry & Momberg (2000), Deignan (1945, 1948a), Dickinson & Dekker (2002b), Duckworth & Hedges (1998), Duckworth, Salter & Khounboline (1999), Gyldenstolpe (1913, 1916), Lekagul & Round (1991), MacKinnon & Phillipps (2000), Medway & Wells (1976), Meyer de Schauensee (1984), Riley (1938), Robinson & Kloss (1919a), Robson (2000), Robson *et al.* (1993a, 1993b), Smythies (1986), Stanford & Mayr (1940–1941), Stepanyan (1995), Strange (2002), Thewlis *et al.* (1996), Wells (2005).

106. Buff-vented Bulbul

Iole olivacea

French: Bulbul de Charlotte **German**: Braunbauchbülbül **Spanish**: Bulbul Oliváceo
Other common names: Dull-brown Bulbul; Charlotte's/Finsch's Bulbul (*charlottae*)

Taxonomy. *I[ole]. olivacea* Blyth, 1844, Singapore.
Often included in a broad genus *Hypsipetes*; when thus treated, current species name becomes invalid, as preoccupied, and name *cryptus* should be used, in addition to which *charlottae* then has priority as the species name. Proposed race *perplexa* (from Labuan Kelambu, in Borneo) invalid, as described from a standard juvenile specimen. Two subspecies recognized.
Subspecies and Distribution.
I. o. olivacea Blyth, 1844 – S Myanmar (Tenasserim), S Thailand (S of 14° N), Peninsular Malaysia, Riau Archipelago and Sumatra (including Batu Is, Bangka and Belitung).
I. o. charlottae (Finsch, 1867) – Anambas Is (E of Peninsular Malaysia), N Natunas and Borneo (including Banggi I).

Descriptive notes. 20–20·5 cm; 20–28 g. A medium-sized, virtually featureless, noisy bulbul with relatively long and slender bill, crown often appearing frizzy when feathers slightly raised. Cap is dark rufescent olive-brown, lores, eyering and upper face smoky grey, shading to ashy brown on ear-coverts; upperparts dull olive-brown, uppertail-coverts dark rufous-brown; upperwing olive-brown, brighter rufous-olive fringing on outer webs of outer secondaries and primaries, slight bronzy sheen on tertials and inner secondaries; tail uniform dark rufous-brown; chin and throat dull white, centre of breast as throat, breast side and flanks ashy olive-brown (forming distinct patch); belly pale cream, undertail-coverts the same but with feather centres ashy brown; iris greyish-white; upper mandible dark pinkish-horn, lower mandible pale grey and fading to pale pinkish towards base; legs yellowish to pinkish-brown. Distinguished from very similar *I. propinqua* mainly by purer grey face contrasting more with dark cap and, especially, brow, less olive wings, less yellow-tinged underparts, no ru-

On following pages: 107. Sulphur-bellied Bulbul (*Ixos palawanensis*); 108. Nicobar Bulbul (*Ixos nicobariensis*); 109. Mountain Bulbul (*Ixos mcclellandii*); 110. Streaked Bulbul (*Ixos malaccensis*); 111. Sunda Bulbul (*Ixos virescens*); 112. Philippine Bulbul (*Ixos philippinus*); 113. Zamboanga Bulbul (*Ixos rufigularis*); 114. Streak-breasted Bulbul (*Ixos siquijorensis*); 115. Yellowish Bulbul (*Ixos everetti*).

fous tinge on undertail-coverts, also by larger bill. Sexes alike. Juvenile is similar to adult but with bill pale, pale margins on wing-coverts and secondaries, light brown eyes. Race *charlottae* is very like nominate, but upperparts darker olivaceous brown, underparts with slightly more brownish, or olivaceous, tinge. VOICE. No complex song described. Call a musical "er-whit" or "wher-it", with sharper, more metallic second note, similar to that of *I. virescens*, thinner, higher-pitched and less nasal than that of *I. propinqua*. Also gives flatter "whirr". Commonest call rendered "cherrit", "chewit", "bueik" or "whe-ic", approaches that of *I. propinqua* but richer, slightly more sustained, with small but noticeable upward inflection, and sometimes given in a short series interspersed with occasional shrill whistling notes.
Habitat. Broadleaf evergreen forest, edges and secondary growth. At Pasoh, in Peninsular Malaysia, no difference in catch-rates between mature forest and 20-year-old regenerated plots. Enters older *Albizia* plantations and peatswamp-forest. Perhaps most frequently encountered at forest edges and along broad roads and tracks through forest, particularly in areas covered with new growth of gap-colonizing trees (e.g. *Macaranga*). Lowlands to 900 m.
Food and Feeding. A generalist, eating fruit and insects. Fruit part of diet includes many figs (*Ficus*), including banyans, and 17 of 25 *Ficus* species studied at Kerau (Peninsular Malaysia) in mean fruit-diameter range 5·4–27·4 mm. Eats fruit and berries (e.g. *Trema orientalis* and *Cissus*) in Borneo; stomachs of specimens from Sumatra contained peel and pips of fruit. Insects reported eaten include orthopterans and fly larvae (Diptera). Forages in interior canopy and middle storey, occasionally in understorey; sometimes descends lower at edges to feed in fruiting shrubs, but never descends to ground; in studies at Pasoh, in Peninsular Malaysia, appeared to spend most time above 3 m. Searches foliage for arthropods; chases flushed items in agile pursuit, and makes short flycatching sallies after passing insects. Distinct morning and evening peaks of foraging activity.
Breeding. On mainland, breeding in Apr–Jul in Peninsular Malaysia, and unconfirmed reports from Jan onwards; well-developed juveniles in Mar in Sumatra. Clutch 2 eggs; both pair-members tend fledglings. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Population probably declining, as lowland forest is disappearing from Sundaic lowlands. This species' tolerance of heavily degraded habitats, however, implies that it is not at immediate risk of extinction: indeed, it is at least as common in edge, disturbed and secondary forest as in mature forest, and hence among the bulbuls most likely to have benefited from selective logging. More comprehensive forest clearance is detrimental. Although previously resident in Singapore, it is now very scarce and irregular following deforestation.
Bibliography. Büttikofer (1887), Collar *et al.* (2001), Danielsen & Heegaard (1995), Davison (1987), Deignan (1948a), Dickinson & Dekker (2002b), Dickinson *et al.* (2002b), Ford & Davison (1995), Gibson-Hill (1949), Hume & Davison (1878), Jeyarajasingam & Pearson (1999), Lambert (1989b), Lekagul & Round (1991), Lim Kim Seng (1991, 1994b), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Mitra & Sheldon (1993), Oberholser (1917b), Rajathurai (1996), Riley (1938, 1939), Robson (2000), Smythies (1957, 1999), Stattersfield & Capper (2000), Thompson (1966), Voous (1961), Vowles & Vowles (1997), Wells (2005).

Genus *IXOS* Temminck, 1825

107. Sulphur-bellied Bulbul

Ixos palawanensis

French: Bulbul de Palawan **German**: Goldaugenbülbül **Spanish**: Bulbul de Palawan
Other common names: Golden-eyed/Olive Bulbul

Taxonomy. *Criniger palawanensis* Tweeddale, 1878, Puerto Princesa, Palawan, Philippines.
Sometimes included in genus *Hypsipetes*. Rather aberrant member of present genus, and possibly better separated in its own, monotypic genus; taxonomy merits further study. Monotypic.
Distribution. Palawan, in W Philippines.

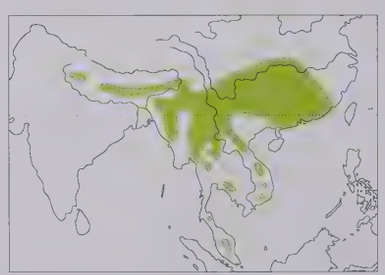
Descriptive notes. 18 cm. Small olive-brown bulbul, lanceolate crown feathers forming slight crest. Crown and ear-coverts are olive-brown with narrow pale shaft streaks; upperparts dull olive-brown; wings and tail brown, pale olive fringing on upperside of flight-feathers and rectrices; throat yellowish-white with olive-yellow streaks, darkening on breast and flanks, where smudged with pale olive and greyish; lower breast, belly and undertail-coverts are primrose-yellow; iris yellowish; bill black above, grey on cutting edges and lower mandible; legs brown. Sexes alike. Juvenile undescribed. VOICE. Poorly known; variety of harsh simple calls, including "chirrup", "chirrup-chi" and "chip".
Habitat. Evergreen forest, edges and secondary growth in mountains.
Food and Feeding. Diet not documented; presumably fruit and insects. Found singly, in pairs or in small flocks.
Breeding. Birds with enlarged gonads in Apr. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Palawan EBA. Uncommon. Very poorly known species. Present in St Paul Subterranean River National Park.
Bibliography. Dickinson *et al.* (1991), duPont (1971), Gregory (2000), Inskipp *et al.* (1996), Kennedy *et al.* (2000), Sharpe (1888a), Stattersfield *et al.* (1998).

108. Nicobar Bulbul

Ixos nicobariensis

French: Bulbul des Nicobar **German**: Nikobarenbülbül **Spanish**: Bulbul de Nicobar

Taxonomy. *Hypsipetes nicobariensis* F. Moore, 1854, Nicobar Islands.
Originally named *Ixocincla virescens*; when placed in present genus or in expanded *Hypsipetes*, however, that specific epithet preoccupied. Placement in present genus, constituent members of which do not seem particularly closely related to each other, is open to debate; full review of genus required. Often included in an expanded *Hypsipetes*; on basis of superficial similarity, has been treated as race of *H. madagascariensis* (along with other Asian forms now grouped under *H. leucocephalus* and *H. ganeesa*). Detailed study required in order to clarify true affinities with members of the two genera. Monotypic.
Distribution. C Nicobar Is.



Descriptive notes. 20–22 cm. Plain, dull, olive bulbul with rather thick and long bill, slightly elongated crown feathers often raised into a crest. Crown is sooty brown or blackish-brown, contrasting with paler brown lores; nape to uppertail-coverts uniform olive-green, tinged brown (amount of brown or green varying individually); wings and tail slightly darker and browner; throat and breast dingy white, subtly tinged yellow (some with sufficient brown on breast to form indistinct breastband, and some much yellower below than others); yellow suffusion on lower underparts; iris brown; bill blackish, dusky yellow lower mandible and cutting edges of upper mandible; legs blackish-grey or dark greenish-brown. Sexes alike. Juvenile is browner above, with no contrast between head and mantle, paler bill than adult. VOICE. Chattering voice apparently recalling that of *Hypsipetes leucocephalus*; noisy, especially when flocking.
Habitat. Primarily forest; also at forest edges and in secondary growth, gardens and plantations, including coconut and rubber (*Hevea*).
Food and Feeding. No information on diet. Usually in pairs or in small parties of 5–6 individuals; loose aggregations of up to 100 sometimes gather in non-breeding season.
Breeding. Evidently breeds early in year, as very young birds found in Feb. No other information.
Movements. Resident.
Status and Conservation. VULNERABLE. Restricted-range species: present in Nicobar Islands EBA. Formerly common; now scarce, probably owing to a combination of factors including habitat destruction and introduced competitors. Natural habitat being lost as a result of conversion to coconut plantations, expansion of human settlements, and infrastructural development; seems to have been displaced from many of its former haunts by *Pycnonotus jocosus* (introduced from nearby Andaman Is). Tillanchong I (17 km²), uninhabited and protected as a reserve, provides some hope for the species, but conservation action should be focused on Katchall and Teressa, where the largest numbers have been seen. Recorded also on Bompoka, Camorta, Nancowry and Trinkut; old report from Pilu Milu, off Great Nicobar, considered dubious. Population control of *P. jocosus* should be considered at sites which are important for this present species.
Bibliography. Abdulali (1964, 1967), Ali & Ripley (1996), Ball (1873), Butchart & Stattersfield (2004), Butler (1899), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Dickinson *et al.* (2002b), Gregory (2000), Grimmett *et al.* (1998), Hume (1874), Richmond (1902), Ripley (1982), Sankaran (1997, 1998), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Tikader (1984).

109. Mountain Bulbul

Ixos mcclellandii

French: Bulbul de McClelland **German**: Grünflügelbülbül **Spanish**: Bulbul de McClelland
Other common names: Rufous-bellied/Green-winged/McClelland's Bulbul

Taxonomy. *Hypsipetes McClellandii* Horsfield, 1840, Assam, India.
Sometimes included in genus *Hypsipetes*. Specific name sometimes misspelt as *macclellandii*. Racial delimitation complex, and thorough review required. Some races may represent separate species, e.g. *canescens* is geographically isolated and does not fit the general pattern of plumage variation; others seem too poorly differentiated or variable to warrant taxonomic recognition. Detailed review of geographical song variation required. Described race *vargus* (from Nepal) appears indistinguishable from and is synonymized with nominate; *binghami* (Southern Shan States, in Myanmar) thought to be a colour morph of *tickelli*, and treated as a synonym of it. Nine subspecies provisionally recognized.
Subspecies and Distribution.
I. m. mcclellandii (Horsfield, 1840) – Nepal, N India (E Himalayas from Uttaranchal E to NE Arunachal, and hills from S Assam S to Mizoram) and NW Myanmar; reported also from SE Tibet.
I. m. ventralis Stresemann, 1940 – W & SW Myanmar (including Arakan); old reports from Bangladesh (Chittagong hills).
I. m. tickelli (Blyth, 1855) – E Myanmar and N Thailand.
I. m. similis (Rothschild, 1921) – S China (W & S Yunnan) and NE Myanmar S to N Indochina.
I. m. holtii (Swinhoe, 1861) – SE China (Guangxi, Jiangxi, Guangdong, Fujian).
I. m. loquax Deignan, 1940 – NW & NE Thailand and S Laos.
I. m. griseiventer (Robinson & Kloss, 1919) – S Vietnam (S Annam).
I. m. canescens Riley, 1933 – SE Thailand and SW Cambodia.
I. m. peracensis (Hartert & Butler, 1898) – S Thailand and N Peninsular Malaysia.

Descriptive notes. 21–24 cm; 27–41 g. Large, noisy, conspicuous bulbul with long slim bill, large square tail, generally bright olive above, with strong chestnut tone on underparts, elongated crown feathers frequently raised into a frizzy, expressive crest, elongated throat feathers often puffed out. Nominate race has crown deep chestnut-brown with fine white shafts (inconspicuous), lores dark ashy grey, rest of face slightly paler ashy grey, becoming ashy brown on forepart of ear-coverts; rear ear-coverts and side of neck light rufous-brown; upperparts bright olive-green, tertials and inner secondaries similar except outer webs edged even brighter; primaries and secondaries have sooty black inner webs, and bright, yellow-tinged olive-green outer webs (showing as conspicuous panel against duller coverts on closed wing); tail olive-green, a shade darker than upperwing-coverts, with shafts deep brown above, yellow-white below; chin and throat greyish with prominent white shaft streaks; breast strongly

tinged dull rusty, especially at side, with thin white shaft lines, upper flanks olive, belly creamy buff with ashy fringing, undertail-coverts yellowish; iris light reddish-brown to dark rich crimson, eyelids edged red; upper mandible dark horn-brown, lower mandible pale grey or pinkish-grey, sometimes darker at tip; legs pale pinkish-brown to light purplish-brown, soles chrome-yellow. Sexes alike. Juvenile is browner above, with duller, browner wings, has plain pale greyish throat, shorter, less shaggy crest, weaker streaking on crown and breast, cinnamon-tinged vent, plain brown or brownish-grey iris. Race *ventralis* has greener upperparts than nominate; *tickelli* has more greenish-olive mantle (sometimes brownish: "*binghami*"), breast duller, crown and crest feathers lanceolate and dull, dark brown with conspicuous pale shaft streaks; *similis* has mantle dull grey-brown, ear-coverts, neck and breast dull dark pinkish-chestnut, wings and tail bright olive-green, belly whitish, undertail-coverts yellowish; *holtii* has forehead light rufous with pale feather centres, crest feathers with pale tips as well as shaft streaks, mantle relatively dark olive-brown, breast ochraceous brown (less rufous), belly pale buff, wings and tail dull green, lower mandible mostly dark; *loquax* differs from previous in paler buffy underparts and buffy yellow undertail-coverts; *griseiventer* has dull brown head, greyish ear-coverts, greyish underparts with practically no fulvous wash on breast and flanks; *canescens* lacks olive and rufous tones, has much grey on underparts, duller and browner on mantle and crown (pale shaft streaks less obvious), with iris much duller, chestnut or orange-brown; *peracensis* has crown darker (lacking rufous), ear-coverts dingy grey, breast ashy brown, rest of underparts lacking rufous or yellow tinges. Voice. Song in India (nominate race) a repetitive, deliberately paced series of screechy, slightly alternating squawks, "chirrut, chewt, chirrut, chewt"; in China, *holtii* said to give a series of 4–5 loud descending notes. Calls (more frequently heard) distinctively high-pitched, metallic, downwardly inflected chirps, "tsiuc" or "chewp"; in Malaysia, include similar but rather feeble, piping "chiep-chiep, chiep", sharp "chio-chip" and penetrating "sneep sneep sneep". Sometimes gives more complex "tchi-chitu" and plaintive, soft, descending mew. Flocks emit call notes almost constantly.

Habitat. Canopy of broadleaf evergreen forest, oak (*Quercus*) forest, rhododendron forest and pine (*Pinus*) forest. Commonly ranges into more open, stunted or secondary habitats, such as edges and adjacent scattered bushes, young secondary growth, light gallery forest, fern tangles along roads, gardens, overgrown edges of old landslips, and elfin summit forest. Occurs at 800–2700 m; perhaps peak abundance at c. 1800–2100 m.

Food and Feeding. A generalist, eating fruit and insects, possibly also nectar. Eats many berries and other small fruits (e.g. *Ficus vasculosa* and *Lindera pipericarpa*); in Myanmar, seen to feed at fruit and flowers of *Heptapleurum*, *Ficus*, cherry, *Maesa*, *Litsea*, *Polygonum*, *Prunus*, *Berberis*, *Polygala*, rhododendrons. Insects taken include large moths (Lepidoptera). Visits flowers, but whether for nectar, for insects or to eat the flowers themselves is not entirely clear. Sometimes solitary, but usually in pairs or in loose, typically single-figure, foraging parties; pairs disperse in breeding season, but parties found more or less throughout year. Gathers at fruiting and flowering trees and shrubs, and commonly attends mixed-species foraging flocks. Found more in treetops than are most *Pycnonotus* species, but also drops to low fruiting bushes to feed. Fruits often plucked during hovering sally. Regularly sallies from prominent perches to catch insects in flight; also snatching trapped insects from spider webs. Sometimes shy, but often tame and sluggish.

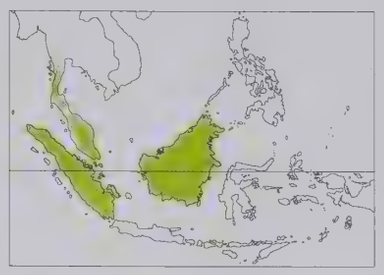
Breeding. May–Aug in NE India, Feb–Aug in N Thailand and Mar–Sept in Peninsular Malaysia. Nest sometimes placed c. 6–13 m above ground, but often much lower down in undergrowth at forest edge, usually slung from the rim between thin twigs of horizontal fork near edge of tree or bush, or sometimes bamboo; one in Nepal (nominate race) was an oval cup, built of ferns, dry leaves, roots, grasses and a little moss, bound with fine black fibres, which also attached it to a slender fork, and those reported historically in India were described as bulky and untidy, with a cup of coarse grass, bamboo leaves, shreds of soft bark and other fibrous materials (no moss), inner lining of fine grass stems mixed with fern roots; one in Myanmar (*tickelli*) was rather different, a small, flimsy structure made of bamboo leaves, held together with moss and cobwebs, lined with fine grass, suspended 1 m above ground in fork of tall bracken, and another, in China (*holtii*), was surprisingly small and frail, suspended 1·5 m up in horizontal fork; a hammock-like nest in Malaysia (*peracensis*) was in low tangle of scrambling ferns on steep bank. Clutch 2–3 eggs, rarely 4; mo information on incubation and fledging periods; both pair-members tend nestlings and fledglings, feeding them with berries and insects.

Movements. Resident, subject to altitudinal movements. In India and Nepal, post-breeding descent to foothills, and occasionally out on to plains. In Cameron Highlands (Peninsular Malaysia), elevational shifts by marked individuals of up to 1000 m, over map distances of up to 1·6 km, were thought possibly to fit within normal (perhaps even diurnal) group foraging range. Race *similis* recorded as a vagrant on Hainan I.

Status and Conservation. Not globally threatened. Generally common throughout range. Fairly common or common in hills of NE India, Nepal, Bhutan, much of Myanmar, N Thailand and Laos; the commonest bulbul in forested uplands of Peninsular Malaysia. Scarce in SW Cambodia, where first recorded in 2000 (in Cardamom Mountains); rare or extinct in Bangladesh, possibly still occurs in Chittagong hills. The fact that it tolerates, or even prefers, disturbed or secondary vegetation and forest edges implies that it is not in any imminent danger. Despite its being a popular target of hunters in N Thailand, Laos and Vietnam, populations there seem not to have suffered.

Bibliography. Ali & Ripley (1996), Ali *et al.* (1996), Bingham (1903), Bingham & Thompson (1900), Caldwell & Caldwell (1931), Cheng Tsohsin (1987), Daltry & Momberg (2000), Davidson (1998), Deignan (1940b, 1945), Dickinson & Dekker (2002b), Dickinson *et al.* (2002b), Duckworth, Salter & Khounboline (1999), Eames *et al.* (2002), Étchécopar & Hüe (1983), Gibson-Hill (1949), Grimmett *et al.* (1998), Harington (1909a), Harvey (1990), Hopwood (1912), Hopwood & Mackenzie (1917), Hume (1888), Hume & Davison (1878), Inskipp & Inskipp (1991), Inskipp *et al.* (2000), Jeyarajasingam (1990), Jeyarajasingam & Pearson (1999), King (1989), Koelz (1954), Lekagul & Round (1991), Lewthwaite (1996), MacKinnon & Phillipps (2000), Madoc (1976), McClure (1964), Medway (1972), Medway & Wells (1976), Meyer de Schauensee (1929, 1984), Pershouse (1916), Rasmussen & Anderton (2005), Riley (1938), Robson (2000), Scully (1879), Singh (1995), Smythies (1986), Stanford & Mayr (1940–1941), Stepanyan (1995), Stevens (1914–1915, 1923–1925), Stresemann & Heinrich (1939), Stuart Baker (1892–1893, 1922–1930), Tobias (1997c), Traylor (1967), Zheng Guangmei & Zhang Cizu (2002).

110. **Streaked Bulbul**



Ixos malaccensis

French: Bulbul malais **German**: Strichelbrustbülbül **Spanish**: Bulbul Malayo
Other common names: Green-backed Bulbul

Taxonomy. *H[ypsipetes]. malaccensis* Blyth, 1845, Melaka, Peninsular Malaysia.
Often placed in genus *Hypsipetes*. Monotypic.

Distribution. S Myanmar (Tenasserim S from 12°30' S), S Thailand, Peninsular Malaysia, Riau and Lingga Archipelagos, Sumatra, Bangka and Borneo.

Descriptive notes. 23 cm; 36–41 g. Medium-large, slender, streaky bulbul with rather long and slender bill. Has lores smoky grey, ear-coverts, supercilium and postocular region greyish-olive; crown dark olive (sometimes slight rufous tinge on forecrown), feathers only slightly elongated; upperparts, including upperwing, the same dark olive colour, tertials and flight-feathers with brighter olive-green fringes on outer webs; tail dark olive-brown, outer webs fringed olive; chin to lower breast olive-tinged ashy grey with white shaft streaks, streaks broadest on breast; flanks pale grey with grey-olive tipping, belly to undertail-coverts uniform creamy white; iris dull reddish-brown to deep red; upper mandible blackish-brown, lower mandible dark brownish horn with paler pinky yellow at base; legs reddish-brown, light brown or grey, claws horn-brown. Sexes alike. Juvenile has upperparts and wings mostly warm rufescent brown, breast less distinctly streaked, iris duller brown. Voice. Often noisy. Song a simple, short, rather high-pitched, slightly descending ditty, "chiri-chiri-chu", "chiru-chiru" and similar, or longer phrases e.g. as "ka-jee ka-jee ka-jee, jueee", sometimes running into delicate descending trills. Loud, harsh rattles or rasping calls given while foraging, and often in flight, transcribed as "jizeer jizeer jizeer".

Habitat. Mature broadleaf evergreen forest and tall secondary forest; sometimes encountered at forest edges and in peatswamp kerangas forest. Lowlands and foothills, occasionally to 1100 m (Peninsular Malaysia) or 1200 m (Borneo).

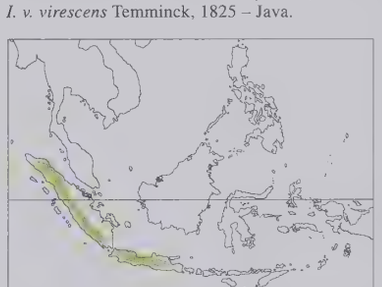
Food and Feeding. Fruit and insects. Many figs taken, including riverside banyans, *Ficus sumatrana* and three (*F. virens*, *F. kerkenhovenii* and *F. stupenda*; mean fruit diameter 7–27·4 mm) of 25 *Ficus* species studied at Kerau, in Peninsular Malaysia. Stomachs of specimens from Sumatra contained seeds, and legs of insects (probably orthopterans). Regularly seen singly or in pairs, sometimes in small (family?) groups; of 108 individuals encountered at Gombak, in Peninsular Malaysia, only eight (7%) were associating with mixed-species flocks. Forages mainly in canopy, occasionally in middle storey. Performs aerial sallies after flying insects.

Breeding. Apr–May, probably also Jun–Jul. In Myanmar, nest reported as a neat cup of moss and bamboo leaves, with lichen and cobwebs interwoven into outer layer, lining of fine dried grass and rootlets; most are probably sited relatively high above ground and therefore difficult to find. Clutch 2 eggs; no information on incubation and nestling periods; both pair-members tend fledglings.

Movements. Resident.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Fairly common to common throughout most of range. Lowland primary forest in Sundaic region is being cleared at a phenomenal rate, and populations of this species must be declining rapidly. Its presence in secondary forests and the more secure foothill forests, however, suggests that it is not at immediate risk of extinction.

Bibliography. Büttikofer (1887), Chasen & Hoogerwerf (1941), Collar *et al.* (2001), Danielsen & Heegaard (1995), Davison (1987), Davison & Chew Yen Fook (1996), Dickinson *et al.* (2002b), Duckworth & Kelsh (1998), Ford & Davison (1995), Gibson-Hill (1949), Holmes (1996), Hume & Davison (1878), Jenkins *et al.* (1996), Jeyarajasingam & Pearson (1999), Lambert (1987), Lekagul & Round (1991), MacKinnon & Phillipps (1993), van Marle & Voous (1988), McClure (1966, 1967), Medway & Wells (1976), Mees (1986), Rajathurai (1996), Riley (1938), Robson (2000), Smythies (1957, 1986, 1999), Stattersfield & Capper (2000), Thompson (1966), Vowles & Vowles (1997), Wells (2005), Wells *et al.* (1978).



111. **Sunda Bulbul**

Ixos virescens

French: Bulbul verdin **German**: Sumatrabülbül **Spanish**: Bulbul de Sumatra
Other common names: Sumatran/Green-winged/Green Mountain/Green-backed/Streaked Bulbul

Taxonomy. *Ixos virescens* Temminck, 1825, Java.
Often placed in genus *Hypsipetes*. Two subspecies recognized.

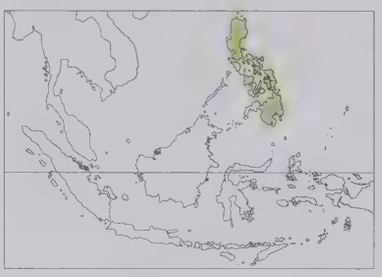
Subspecies and Distribution.
I. v. sumatranus (R. G. W. Ramsay, 1882) – W Sumatra (highlands of Barisan Range).
I. v. virescens Temminck, 1825 – Java.

Descriptive notes. 20 cm. Medium-large, slender, streaky bulbul, elongated crown feathering forming small crest. Nominate race has grey crown, greyish-olive cheeks with whitish shaft streaks; upperparts olive-green, brighter and yellower fringing on outer webs of flight-feathers and tail feathers; throat white, contrasting with darker breast, each breast feather conspicuously marked with white shaft and adjoining streak down centre; flanks heavily streaked olive-brown, belly and undertail-coverts creamy white; iris reddish-brown or red; bill black, sometimes grey base of lower mandible; legs blackish-brown or dark grey. Sexes alike. Juvenile is similar to adult but duller, with brown iris. Race *sumatranus* is similar to nominate, but has upperparts, upperwing-coverts and fringing of primaries and secondaries warm olive-brown (lacking yellow tones), ear-coverts brown with pale shaft streaks, throat and breast warm olive-brown (like upperparts) and streaked white. Voice. Calls "chiit-chiit-chiit", and sharper "twink" sounding like call of European Chaffinch (*Fringilla coelebs*).

Habitat. Evergreen forest, edges and secondary growth in mountains, 800–3000 m; highest densities in tall montane forest.

Food and Feeding. A generalist, feeding on fruit and insects. Stomachs of birds from N Sumatra contained mostly fruit ("one round, orange-coloured berry, one dark-blue berry, brown and black pips, fruitpeel, red-pulp, etc."); one individual had been eating "small, black beetles". In Java, recorded as eating variety of fruits, including those identified as *Ficus*, *Lantana camara*, *Glochidion*, *Rubus* and *Podocarpus imbricatus*, as well as invertebrates, including orthopterans, coleopterans, alate termites (Isoptera), caterpillars, and spiders (Araneae). Often found singly or in pairs, when often sluggish and inconspicuous; also forms small noisy parties of 3–6 individuals. Often accompanies mixed-species foraging flocks; in one study, majority of sightings of present species were of individuals in such flocks. Forages in canopy and middle storey.

Breeding. Apr–May in Java. Nest a strongly built, cup-shaped structure, often placed high above ground, sometimes above 10 m, apparently usually attached by upper rim to forking twigs (rather than supported from below) in tree or shrub in forest, at forest edge or in adjacent clearing. Clutch 2 eggs, sometimes only 1; no information on incubation and nestling periods.



Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Sumatra and Peninsular Malaysia EBA and Java and Bali Forests EBA. Fairly common in highland protected areas, such as Kerinci-Seblat National Park, in Sumatra, and Gunung Gede-Pangrango National Park, in Java. As forest in its altitudinal range is not immediately threatened, and because it tolerates highly degraded habitats, this species faces no imminent threat of extinction.
Bibliography. Andrew (1985), Becking (1989), Chasen & Hoogerwerf (1941), Gregory (2000), Hellebrekers & Hoogerwerf (1967), Hoogerwerf (1949a), MacKinnon (1988), MacKinnon & Phillipps (1993), MacKinnon *et al.* (2000), van Marle & Voous (1988), Salvadori (1887), Sargeant (1997), Stattersfield *et al.* (1998), Tobias & Phelps (1994).

112. **Philippine Bulbul**

Ixos philippinus

French: Bulbul des Philippines **German**: Rotbrustbülbül **Spanish**: Bulbul Filipino
Other common names: Rufous-breasted Bulbul

Taxonomy. [*Turdus*] *philippinus* J. R. Forster, 1795, Luzon, Philippines.
Original name species *philippensis* invalid, as preoccupied. Often placed in genus *Hypsipetes*. Often treated as conspecific with *I. rufigularis*, but is much smaller, and no evidence of intergradation where ranges approach each other. Distribution and validity of races provisional; some are weakly differentiated (e.g. *saturatior*) and may not warrant recognition, and others possibly represent separate species; thorough review required. Five subspecies provisionally recognized.
Subspecies and Distribution.
I. p. philippinus (J. R. Forster, 1795) – N Philippines (Luzon, Corregidor, Fortune, Lubang, Polillo, Calagua Is, Marinduque, Banton, Catanduanes).
I. p. mindorensis (Steere, 1890) – Mindoro and Semirara.
I. p. parkesi (duPont, 1980) – Burias.
I. p. guimarasensis (Steere, 1890) – WC Philippines (Ticao, Masbate, Carabao, Borocay, Panay, Gigantes, Calagna-an, Sicogon, Bantayan, Guimaras, Negros, Verde).
I. p. saturatior (Hartert, 1916) – EC & S Philippines (Samar, Buad, Balut, Biliran, Leyte, Cebu, Olango, Mactan, Bohol, Panaon, Calicoan, Mindanao except Zamboanga Peninsula, Cabo, Talicud, Pujada).

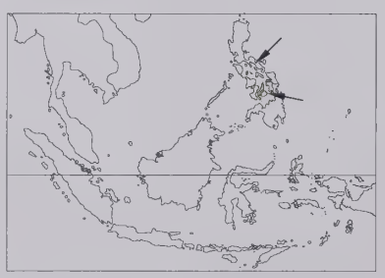
Descriptive notes. 22 cm; male 25–45 g, female 22–42 g. Large, noisy, conspicuous bulbul. Nominate race has brownish-grey crown, each feather with light grey fringing; ear-coverts brown with pale shafts (streaked effect); upperparts olive-brown, wings and tail similar, olive fringing on flight-feathers and rectrices; chin and throat washed rufous, with distinct pale shaft streaks; breast rufous-brown; belly, undertail-coverts and underwing dirty white with yellowish wash, thighs and flanks olive; iris dark brown to chestnut; bill black or blackish-horn; legs dark brown to greyish-horn. Sexes alike. Juvenile is similar to adult, but crown and upperparts browner, throat more buff, contrasting pale shaft streaks on throat and breast lacking or inconspicuous. Race *parkesi* is considerably larger than nominate; *saturatior* is very similar to nominate but slightly larger; *guimarasensis* has duller rufous throat, larger bill, substantially longer wing; *mindorensis* has larger bill, deeper olive throat and breast (virtually lacking rufous, inconspicuous shaft streaking), darker abdomen. Voice. Musical. Distinct racial variation inadequately sampled, but nominate race gives "deut doo doo doo da-leee-eut", descending and then rising at end; *saturatior* "deut deut leee deut duet duet duet" or shorter "duet do-lee-eut", both versions rising at "lee" note; *guimarasensis* has longer call beginning with drawn-out "deut deut deut", accelerating into complex series of musical notes similar to songs of other races; *mindorensis* a teetering "we-to we-to we-to-to", leveling off at end. All races give particularly raspy call when alighting or taking flight.
Habitat. Interior of broadleaf evergreen forest, forest edge, shrubby clearings and secondary growth; also in well-cultivated areas with plenty of trees, including coconut groves. Able to survive on small shrubby islets offshore, where often one of the only passerines found. Lowlands, foothills and submontane zones, to 2000 m.
Food and Feeding. Diet includes much fruit and probably some insects, but no details available. Usually found singly or in pairs, less often in small (family?) parties; forages understorey to canopy.
Breeding. Breeding activity recorded Jan–Jul; birds with enlarged gonads and a nestling found in Apr on Mindanao, and birds with enlarged gonads and one female almost ready to lay in Apr on Samar. Cup-shaped nest composed of mixed grasses, fine rootlets, twigs and leaf midribs, woven together and bound compactly with spider webs and cocoon threads, outside diameter 11·6 cm, inside 6·8 cm, normally attached securely in upright fork of small tree or shrub in understorey or in clearing adjacent to forest. Clutch 2–3 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally common or very common throughout much of range. Its tolerance of degraded and shrubby habitats suggests that it faces no imminent threat of extinction.
Bibliography. Alonzo-Pasicolan (1992), Brooks, Dutson, Gabutero & Timmins (1995), Brooks, Dutson, King & Magsalay (1996), Brooks, Evans *et al.* (1992), Delacour & Mayr (1946), Dickinson & Dekker (2002b), Dickinson, Dekker *et al.* (2002b), Dickinson, Kennedy & Parkes (1991), duPont (1971), Dutson *et al.* (1992), Evans, Dutson & Brooks (1993), Goodman & Gonzales (1990), Hartert (1916), Kennedy *et al.* (2000), Ogilvie-Grant & Whitehead (1898), Rand & Rabor (1959b, 1960), Ripley & Rabor (1958), Robson & Davidson (1995), Steere (1891).

113. **Zamboanga Bulbul**

Ixos rufigularis

French: Bulbul à gorge rousse **German**: Zamboangabülbül **Spanish**: Bulbul Gorgirrufo
Other common names: Philippine Bulbul (in part), Rufous-breasted Bulbul (in part)

Taxonomy. *Hypsipetes rufigularis* Sharpe, 1877, Malamaui islet and Isabela, Basilan, Philippines.
Often placed in genus *Hypsipetes*. Often treated as conspecific with *I. philippinus*, but is much larger, and no evidence of intergradation where ranges approach each other. Has previously been treated as including race *haynaldi* of *I. everetti*. Monotypic.
Distribution. W Mindanao (Zamboanga Peninsula) and Basilan, in S Philippines.



Descriptive notes. 24 cm; 48–71 g, average 59 g. Medium-large, conspicuous bulbul. Crown is dark brown narrowly streaked greyish, upperparts olive-brown; upperwings brown, olive fringing on outer webs of flight-feathers; tail brown with vague olive fringing; chin, throat and breast rufous, mostly lacking shaft streaks; belly, undertail-coverts and underwing-coverts whitish, washed yellow, thighs and flanks olive; iris dark brown; bill black to brownish-horn; legs dark brown to brownish-horn. Differs from rather similar *I. philippinus* in considerably larger size, and lack of conspicuous streaking on throat. Sexes alike, male possibly larger than female. Juvenile undescribed. Voice. Simple monosyllabic calls "chuk", "tweer" and "choik", similar to those of *Pycnonotus goiavier*. Presumed song a rather uninspired "chigur-chigur-chigur-chigur-chigur", rising on the "chi" and falling on "gur"; also faster "chli-chli-chli", usually in series of c. 10 syllables in 2 seconds.
Habitat. Forest and forest edge; tends to be commonest in intact forest.
Food and Feeding. Often visits fruiting trees; probably supplements diet with insects, but no details available. Usually found in small groups in upper and middle levels of forest; often seen in canopy.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Mindanao and the Eastern Visayas EBA. Supposedly common in limited range, but recent searches have produced very few records, suggesting that it is fairly uncommon. Was reportedly numerous around L Lanao, but seems to have declined. Rapid habitat destruction elsewhere in Philippines is causing steep declines in forest fauna, pushing many species closer to extinction. Further surveys required in order to assess whether this species is suffering the same fate. Not known from any protected areas; appropriately sited reserves need to be established on the Zamboanga Peninsula.
Bibliography. Butchart & Stattersfield (2004), Collar, Andreev *et al.* (2001), Collar, Mallari & Tabaranza (1999), Dickinson & Dekker (2002b), Dickinson, Dekker *et al.* (2002b), Dickinson, Kennedy & Parkes (1991), duPont (1971), Gregory (2000), Kennedy *et al.* (2000), Mallari *et al.* (2001), Rand & Rabor (1959b), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

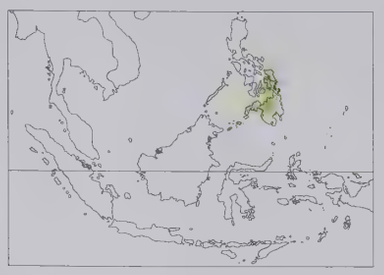
114. **Streak-breasted Bulbul**

Ixos siquijorensis

French: Bulbul de Siquijor **German**: Schieferkopfbülbül **Spanish**: Bulbul de Siquijor
Other common names: Slaty-crowned/Mottle-breasted/Siquijor Bulbul

Taxonomy. *Iole Siquijorensis* Steere, 1890, Siquijor, Philippines.
Taxonomy unsettled. Race *cinereiceps* is vocally, morphologically and behaviourally rather different from others, and likely to merit treatment as a separate species. Nominate race and *monticola* are more similar to each other, but differences may exceed those usually acceptable at race level. Thorough review of species limits necessary. Three subspecies provisionally recognized.
Subspecies and Distribution.
I. s. cinereiceps (Bourns & Worcester, 1894) – Tablas and Romblon, in C Philippines.
I. s. monticola (Bourns & Worcester, 1894) – Cebu.
I. s. siquijorensis (Steere, 1890) – Siquijor, in SC Philippines.

Descriptive notes. 26·5 cm. Large, noisy, conspicuous bulbul. Nominate race has cap to nape very dark brown (giving black-headed impression); upperparts dark olive-brown, feathers narrowly fringed with grey, paler on rump; wings dark olive-brown, wing-coverts and secondaries broadly tipped whitish; tail also dark olive-brown, with ill-defined buffy tips; chin and throat whitish, feathers narrowly fringed with brown; upper breast light greyish-brown with dark brown streaks and dull white shafts, lower breast, belly and undertail-coverts pale grey, slightly smudged buffy-yellow, especially on belly, flanks tan; iris dark brown; upper mandible black or dark brownish-horn, lower mandible dark brown or light brownish-horn; legs blackish-brown. Sexes alike. Juvenile undescribed. Race *monticola* differs from nominate in having paler crown, more rufous back, whiter throat, smaller size; *cinereiceps* differs in grey crown, white throat, olive-brown breast with broad white streaks. Voice. Race *cinereiceps* has varied repertoire, including strident whip-like "whit" notes, often given in complex phrase as "whit pu whit tooer whit whee-er" or "pu-er whit pu-er whit"; *monticola* known to give loud raucous screech.
Habitat. Forest, forest edge, second growth and clearings; at all altitudes (although highest points within its range not particularly high). Some races also in highly degraded scrub, but usually in much lower numbers than found in taller scrub; usually absent from low scrub that is not adjacent to taller growth. On Siquijor, Tablas and Romblon, where *I. philippinus* absent, nominate race and *cinereiceps* tend to be generalists, living in open shrubby habitats as well as in forest. On Cebu, race *monticola* much more specialized on forest, while *I. philippinus* occupies the open-country niche on that island.
Food and Feeding. Small groups recorded at all levels in forest. No other information.
Breeding. Nesting recorded in Jun. No other information.
Movements. Resident.
Status and Conservation. ENDANGERED. Restricted-range species: present in Cebu EBA; also in the Tamblas, Romblon & Sibuyan and Siquijor Secondary Areas. Generally common on Siquijor, where recorded density of 1–3 pairs/ha of habitat; several thousand individuals thought to survive. On Cebu, *monticola* is very rare and often thought extinct, but a few recent sightings at or near the Tabunan reserve; perhaps especially threatened because more reliant on tall forest; this species' habitat niche in scrub appears to have been usurped on Cebu by *I. philippinus*, and the spread of that dominant form perhaps underlies the near-extinction of *monticola*. Race *cinereiceps* undoubtedly rare, as natural habitats have almost been removed from Tablas and Romblon; if elevated to species rank, this taxon would probably be treated as Critical. A century ago, forest cover on Tablas was extensive, but by 1990s only a few small patches were left. Focused conservation action at key



sites is required, and field and laboratory work should address taxonomic issues. Habitat on Tablas, Romblon and Siquijor needs protection, and the Tabunan project on Cebu should be expanded (if *monticola* survives).
Bibliography. Allen (2003), Anon. (1997b), Brooks *et al.* (1995), Butchart & Stattersfield (2004), Collar & Andrew (1988), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Collar, Mallari & Tabaranza (1999), Delacour & Mayr (1946), Dickinson *et al.* (1991), duPont (1971), Evans, Dutson & Brooks (1993), Evans, Magsalay *et al.* (1993), Kennedy *et al.* (2000), McClure & Leelavit (1972), McGregor (1907, 1908, 1909–1910), Rand & Rabor (1959b, 1960), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Steere (1891).

115. **Yellowish Bulbul**

Ixos everetti

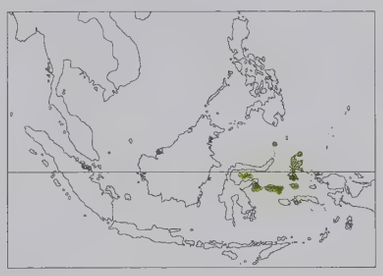
French: Bulbul d'Everett **German**: Everettbülbül **Spanish**: Bulbul de Everett
Other common names: Yellow-washed/Plain-throated/Everett's Bulbul

Taxonomy. *Criniger Everetti* Tweeddale, 1877, Surigao, Mindanao, Philippines.
Taxonomy unsettled. Races are geographically variable in both morphology and voice; *haynaldi* in particular seems well differentiated, and has previously been placed with *I. rufigularis*. Proposed race *samarensis* (from Samar) indistinguishable from nominate, and considered better synonymized with it. Full review, including genetic analysis, and investigation of vocal variation based on adequate sample, is required in order to ascertain whether more than one species involved. Three subspecies provisionally recognized.
Subspecies and Distribution.
I. e. everetti (Tweeddale, 1877) – EC & SE Philippines (Samar, Biliran, Leyte, Panaon, Dinagat, Siargao, Bucas, W & C Mindanao).
I. e. catarmanensis (Rand & Rabor, 1969) – Camiguin Sur, in SC Philippines.
I. e. haynaldi (W. Blasius, 1890) – SW Philippines (Jolo, Tawi-Tawi, Sanga Sanga, Bongao).
Descriptive notes. 24–25·5 mm; male 52–67 g, female 52–62 g. Large, noisy, conspicuous bulbul. Nominate race has olive-green crown, feathers with brighter and yellower terminal edges, giving a somewhat streaky appearance; upperparts yellowish-olive, more olive on wings and tail, with yellower fringing on flight-feathers; chin yellowish; throat and upper breast cinnamon, washed yellow, becoming browner on ear-coverts and breast; central belly, undertail-coverts, feather shafts on underside of tail, and feathers at carpal joint all green-tinged bright yellow, flanks olive; iris dark brown or reddish-chestnut; bill blackish-grey, sometimes paler grey (difference possibly age-related); legs blackish-grey. Sexes alike, male on average larger than female. Juvenile undescribed, probably a duller version of adult. Race *catarmanensis* is larger than nominate, wing significantly longer, and generally darker, with crown brownish-black and contrasting with dark greenish-olive upperparts, flanks darker olive; *haynaldi* is much duller and slightly larger, with upperparts distinctly brownish-olive, underparts darker (including duller ochraceous wash on throat, much duller yellow breast and belly), wing shorter. Voice. Call a long "peeeee" or "peeeeee-yuk". Song melodious, apparently geographically variable. On Camiguin Sur, race *catarmanensis* gives fluty phrase of 7- 8 notes, rising and falling, "wee-wee wo wee wee-wee wo", followed by "wu-wu-wu-wu" or stuttering "tu-tu-tu-tu"; on Mindanao (nominate) a clear descending 2-second series of whistles, "doo dee-dee-dee-dee-dee dee-boy-aay dee-boy-aaaay", last syllable ascending; on Tawi-Tawi (*haynaldi*) a melodious whistled jingle lasting 4 seconds.

Habitat. Forest, forest edge and secondary growth, below 1000 m; tends to prefer intact forest.
Food and Feeding. Eats fruit and probably insects, but no details on diet or foraging strategy available. Small groups travel either independently or with mixed flocks, at all levels, usually in upper understorey or middle storey.
Breeding. Birds with enlarged gonads in Mar–Jun. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Mindanao and the Eastern Visayas EBA and Sulu Archipelago EBA. Remains fairly common throughout much of its range. Although this species prefers intact forest, it is able to survive in small forest patches in now largely deforested regions.
Bibliography. Dickinson & Dekker (2002b), Dickinson *et al.* (1991), Diesmos & Pedregosa (1995), duPont (1971), Dutson *et al.* (1996), Kennedy *et al.* (2000), Mallari *et al.* (2001), Rabor (1955), Rand & Rabor (1959b, 1960, 1969), Stattersfield *et al.* (1998).

Genus *THAPSINILLAS* Oberholser, 1905

116. Northern Golden Bulbul



Thapsinillas longirostris

French: Bulbul des Sula **German**: Sulabülbül **Spanish**: Bulbul de la Sula
Other common names: Long-billed Bulbul; Golden Bulbul (when treated as conspecific with *T. affinis*)

Taxonomy. *Criniger longirostris* Wallace, 1863, Sula Islands, Indonesia.
Often placed in an expanded genus *Hypsipetes*, but morphological and vocal distinctions seem too great to permit such treatment. Has also been placed in *Alophoixus*, but genus probably closest to *Ixos everetti*. Usually treated as conspecific with *T. affinis*, but differs vocally. Races exhibit considerable variation in morphology and, particularly, in vocalizations, and probably represent more than one species; full review, including genetic analysis, is required. Six subspecies provisionally recognized.

Subspecies and Distribution.
T. l. platenae (W. Blasius, 1888) – Sangihe I.
T. l. aurea (Walden, 1872) – Togian Is.
T. l. harterti (Stresemann, 1912) – Banggai Is.
T. l. longirostris (Wallace, 1863) – Sula Is.
T. l. chloris (Finsch, 1867) – Morotai, Halmahera and Bacan.
T. l. lucasi (Hartert, 1903) – Obi.

Descriptive notes. 21–22 cm. Large, conspicuous, essentially olive-coloured bulbul with long bill, weak rictal bristles, short legs and weak feet. Nominate race has head, including lores, and upperparts yellowish-olive, short hair-like plumes on hindneck; yellow below, olive shade on breast, strong olive tinge on flanks; iris reddish-brown or dull crimson; bill black or blackish-brown, slightly paler horn at base and along cutting edges; legs pale purplish-brown or dark fleshy brown, soles

rosy, claws greyish. Sexes similar, female eye possibly duller and paler (immature?). Juvenile is slightly duller than adult, with duller and paler iris. Race *platenae* has bright yellow loral spot, light shaft streaking on upperparts; *aurea* resembles nominate, but with much yellower rump, brighter, more golden-yellow underparts; *harterti* differs from nominate in having more olive on breast, which contrasts more strikingly with yellow throat; *chloris* has dusky lores and cheeks, olive-green upperparts, dusky yellow breast and sides (paler on throat), dull olive tail (lacking yellow); *lucasi* is generally brighter than previous, with golden-yellow loral spot, underparts much yellower and less olivaceous, said also to have deep brown iris, pale olive-green bill (darker on culmen) and bluish-grey legs and feet. Voice. Often noisy. On Sangihe, race *platenae* gives high, peeved, nasal "nyeuk!" and deeper, more thrush-like "puk!" while foraging; song appears to consist of a choppy and erratic series of glancing hard notes (harder and less jumbled than in other races). On Taliabu, nominate race gives emphatic husky chattering "che" or "chir!" notes, often accelerating into repetitive, loud, fluty and melodious song phrase (e.g. "che-che-che-chiwiyo-chiwiyo-chiwiyoo"), whole sequence given every few seconds; also produces long meandering sequences of clipped notes of varying pitch and inflection. On Halmahera, *chloris* song a hurried, cheery, jumbled babbling, recognizably bulbul-like, e.g. "chikwi-chikwi-chikwidilyu", often repeated after short intervals (1–2 seconds), and interspersed with longer phrases that tumble down scale at end, "chikwi-chikwi-chikwid-dlyudidlydidlydidlydyu". On Obi, a frequent call of *lucasi* transcribed as "tweeuwip", and groups gave raucous calls reminiscent of Red-flanked Lorikeet (*Charmosyna placentis*) but without latter's harsh or scratchy quality. Song of all races lacks long sliding notes and descending cadence prevalent in song of *T. affinis*. Several races (including *chloris* and nominate) utter high, ringing, slightly nasal, lorikeet-like "twee, twee" notes, often in series, or long nasal whining notes ("wiiiiieeee"), but neither of these call types thought to be given by *platenae*.

Habitat. Prefers interior of broadleaf evergreen forest, or light woodland, from sea-level to 1700 m. On Taliabu (Sula Is), nominate race occurs in primary forest, secondary forest and clearings, from lowlands to montane zone, but seems commonest in montane primary forest. Most races (including *aurea*, *harterti* and nominate) not confined to intact forest, thriving in secondary growth and plantations; often found in scrub at edge of disturbed forests on Obi (*lucasi*). On Sangihe, however, race *platenae* usually absent from secondary growth and plantations, showing strong preference for small remnants of relatively intact forest, up to c. 1000 m.

Food and Feeding. Diet and foraging strategy undocumented; thought to eat fruit and insects. On Sangihe, usually encountered in groups of 3–6 individuals, sometimes up to ten; in Banggai Is (race *harterti*) groups of 3–4 individuals were commonly seen.

Breeding. Nest containing 2 eggs found in Sula Is (nominate) in Oct–Nov; individual carrying nesting material in Dec on Obi (*lucasi*); birds in breeding condition in Sept on Halmahera (*chloris*). No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Said to be common or abundant on Banggai (race *harterti*), Taliabu and other islands in Sula Group (nominate), Obi (*lucasi*) and Halmahera (*chloris*). On Obi, up to ten recorded daily during a recent visit, and on Halmahera this species was noted at about half (162) of all point localities during one survey of forest. Sangihe race *platenae* is restricted to ridge forest on Gunung Sahengbalira, where thought that only 20–230 individuals survive; as this taxon may well qualify as a distinct species, it requires immediate conservation attention; fortunately, a conservation project is already under way to protect forest at this site.

Bibliography. Bishop (1992), Coates & Bishop (1997), Davidson & Stones (1993), Delacour (1943), Dickinson & Dekker (2002b), Dickinson *et al.* (2002b), Hartert (1898), Indrawan *et al.* (1997), Linsley (1995), Meyer & Wiglesworth (1898), Poulsen & Lambert (2000), Poulsen *et al.* (1999), Riley (1997a, 1997b, 2002), Stones *et al.* (1997), Wallace (1862), Wardill & Riley (1999), White & Bruce (1986).

117. **Southern Golden Bulbul**

Thapsinillas affinis

French: Bulbul à queue d'or **German**: Goldschwanzbülbül **Spanish**: Bulbul Colidorado
Other common names: Golden Bulbul (when treated as conspecific with *T. longirostris*)

Taxonomy. *Criniger affinis* Hombron and Jacquinot, 1841, Waru, Seram, Indonesia.
Often placed in an expanded genus *Hypsipetes*, but morphological and vocal distinctions seem too great to permit such treatment. Has also been placed in *Alophoixus*, but genus probably closest to *Ixos everetti*. Usually treated as conspecific with *T. longirostris*, but differs vocally. Although race name *mysticalis* often given as *mystacalis*, original spelling stands, as no official emendment has been made. This race exhibits pronounced morphological and vocal differences from nominate and *flavicaudus*, and may represent a separate species. Three subspecies provisionally recognized.

Subspecies and Distribution.
T. a. mysticalis (Wallace, 1863) – Buru.
T. a. affinis (Hombron & Jacquinot, 1841) – Seram.
T. a. flavicaudus (Bonaparte, 1850) – Ambon.

Descriptive notes. 22–24 cm; 46 g. Large, conspicuous, olive and yellow bulbul with long bill, weak rictal bristles. Nominate race has small bright yellow spot on lores; otherwise, yellowish-olive above, short hair-like plumes on hindneck, distal third of tail conspicuously bright yellow; underside similar to upperside, but paler; iris warm brown to bright blood-red; bill blackish, paler horn base and cutting edges; legs dark slate. Sexes alike. Juvenile not described. Race *flavicaudus* is much as nominate but slightly longer-winged, tends to be lighter and yellower on upperside and breast, with deeper yellow throat; *mysticalis* is quite different, lacking yellow in tail, has yellow on lores, underparts strongly olive-green with paler shaft streaks, contrasting yellow chin, iris possibly dark brown or black (verification needed). Voice. Song on Seram and Ambon (nominate, *flavicaudus*) a distinctive mournful series of sweet and minor-key notes, lasting 2–4 seconds, slightly erratic or meandering in pace and note length, but essentially slow and leisurely, sliding down scale almost throughout (sometimes slight terminal rise), usually given in bouts, with intervals of 10–20 seconds between songs, sometimes interspersed with harsh single "chrek" or "kruk" notes (these often given while foraging, occasionally in chattering series). Song on Buru (*mysticalis*) vaguely similar but much more complex, beginning with a series of chipping notes (sounding like "kek, kek..."), sometimes involving meandering pitch changes, followed by sequence of whistled notes so distinctly upslurred or warbled as to be polysyllabic, whole effect being of higher-pitched and more tinkling song than that of other two races; Buru race also produces longer, chattering song-like phrase with clipped notes (rather than whistles), tumbling in pitch at end, reminiscent of *Pycnonotus* in tone. At least on Seram (nominate), also a raucous series of piercing, parakeet-like notes (alarm?), sometimes starting and ending more hesitantly, "ki-ki-ki-ki-kréé!-ktéé!-kréé!-kre, kr, kr, kr".

Habitat. Broadleaf evergreen forest, or light woodland, from sea-level to 1700 m. On Seram, occurs from sea-level to submontane forest at 950 m, but seems commonest at lower and middle altitudes. Tolerant of highly degraded forest in lowlands of Seram and Buru, occurring in small gardens cut into forest and in secondary forest down to sea-level in some areas.

Food and Feeding. No information on diet. Occurs at all levels, from understorey to subcanopy. On Seram, often forages with mixed-species flocks in middle storey, and occasionally on forest floor, hopping among leaf litter, in manner of a thrush (Turdidae).

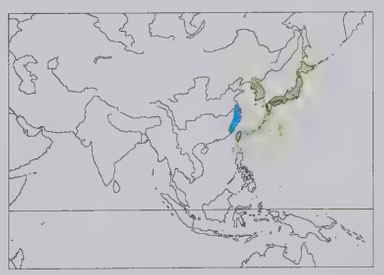
Breeding. Nest containing 2 eggs found in Feb on Buru. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Not evaluated. Fairly common throughout Seram, occurring in Manusela National Park. In E Seram was found to be common at all altitudes from sea-level to 900 m, and one of the most commonly encountered bird species, especially at low altitudes; numbers seen per 100 hours of fieldwork were 98 at Wae Fufa (c. 500 m) and 213 at Hoti (50 m), with respective figures rising to 193 and 231 when those only heard (not seen) are included; in addition, 374 seen/heard per 100 hours at Wae Salas (100 m). Not in any immediate danger of extinction.

Bibliography. Bowler & Taylor (1989, 1993a), Coates & Bishop (1997), Delacour (1943), Dickinson & Dekker (2002b), Isherwood *et al.* (1997), Marsden (1998), Poulsen & Lambert (2000), Siebers (1930), White & Bruce (1986).

Genus *MICROSCELIS* G. R. Gray, 1840



118. **Brown-eared Bulbul**

Microscelis amaurotis

French: Bulbul à oreillons bruns **German**: Orpheusbülbül **Spanish**: Bulbul Orejipardo
Other common names: Japanese/Chestnut-eared Bulbul

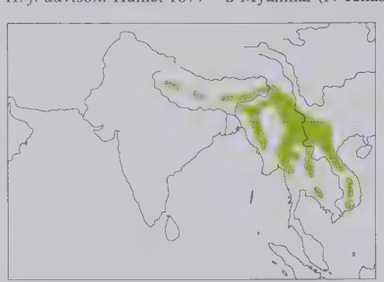
Taxonomy. *Turdus amaurotis* Temminck, 1830, Japan.
Usually placed in *Ixos* or *Hypsipetes*, but divergent morphology suggests that it belongs in its own genus. When placed in an expanded *Hypsipetes* (then also including *Thapsinillas*), race name *harterti* becomes invalid, as preoccupied, and alternative name *nagamichii* is available. Several of the listed races seem weakly differentiated, and possibly invalid. In addition, proposed races *hensoni* (from Hokkaido), *kanrasani* (Quelpart I) and *septentrionalis* (S Sakhalin, non-breeding) considered synonymous with nominate; *insignis* (S Ryukyus) doubtfully distinct from *pryeri* and thus merged with it. Eleven subspecies provisionally recognized.

Subspecies and Distribution.
M. a. amaurotis (Temminck, 1830) – Japan S from Hokkaido (except S Kyushu), and S Korea; non-breeding S to E China and Ryukyu Is.
M. a. matchiae Momiyama, 1923 – S Japan (S Kyushu).
M. a. ogawae (Hartert, 1907) – N Ryukyu Is.
M. a. pryeri (Stejneger, 1887) – C Ryukyu Is.
M. a. harterti (Nagamichi Kuroda, 1922) – extreme S Ryukyus (Yonaguni-jima), Taiwan and Lanyu.
M. a. borodinonis (Nagamichi Kuroda, 1923) – Borodino Is (Kita-daito-jima).
M. a. squamiceps (Kittlitz, 1831) – Bonin Is.
M. a. magnirostris (Hartert, 1905) – Volcano Is (Kito-iwo-jima, Iwo-jima).
M. a. batanensis (Mearns, 1907) – extreme N Philippines (Batan, Ivohos, Sabtang, Babuyan Claro).
M. a. fugensis (Ogilvie-Grant, 1895) – N Philippines (Calayan, Dalupiri, Fuga).
M. a. camiguinensis (McGregor, 1907) – N Philippines (Camiguin Norte).

Descriptive notes. 28 cm. Large, boisterous, highly conspicuous bulbul, elongated and pointed crown feathers forming slight crest; strong undulating flight. Nominate race has crown and nape feathers pale ashy grey, tipped greyish-white; ear-coverts and side of neck chestnut; upperparts dark ashy grey, wings and tail slightly browner than back; throat and breast grey, lower breast and centre of belly with increasingly larger white spots, flanks and thighs grey-brown, undertail-coverts dark grey, broadly edged white; iris red-brown to dark brown (variation possibly age-related); bill dark brown to black; legs dark brown to brownish-pink. Sexes similar. Juvenile is browner than adult, lacking silvery wash. Race *matchiae* has greyer chestband than nominate; *ogawae* has longer wings, pale grey belly and lower breast; *borodinonis* resembles previous, but has paler underparts, darker chestnut ear-coverts and throat, broader olive margins on upperpart feathering, especially crown, back and tail; *pryeri* is similar to nominate but smaller, with cap darker, upperparts more olivaceous, underparts buffy brown (rather than grey),

On following pages: 119. Ashy Bulbul (*Hemixos flavala*); 120. Cinereous Bulbul (*Hemixos cinereus*); 121. Chestnut Bulbul (*Hemixos castanonotus*).

broad collar of warm brown across lower throat; *harterti* is browner throughout, becoming dark rufous on breast; *squamiceps* is slightly smaller than nominate, underparts tinged brown (rather than grey), broad dusky pectoral band; *magnirostris* is similar to previous, but has stronger bill, paler upperparts, narrower rufous collar on lower throat; *batanensis* is larger, with pale forehead, chestnut wash on breast; *fugensis* is like previous but much smaller, with greyer forehead; *camiguinensis* is also similar, but smaller, with greyer flanks. VOICE. Noisy; loud "shreep" and "weesp" notes given throughout year. In Philippines, voice described as harsh "pee-yuk", or descending, accelerating series, "pee-yuk p-uk p-uk p-uk".
Habitat. Deciduous, mixed and evergreen forests in lowlands and foothills, to 1600 m (occasionally 2100 m) in breeding season; in winter, occurs in open agricultural country with groves of trees and hedgerows. Also in suburbs and urban areas, parks and gardens.
Food and Feeding. Eats a wide variety of berries, including holly (*Ilex integra*); also citrus fruits (especially mikan oranges) and leaf vegetables during winter in Japan. Also visits gardens to forage on nectar-rich camellias and other flowers. Sometimes eats insects. Normally occurs in groups. Berries usually plucked while bird is perched. Aggressive and dominant at winter birdfeeders.
Breeding. Apr–Jul, sometimes Aug; multi-brooded, at least in S. Builds sturdy cup-shaped nest 1·5–4·5 m up in lower branches of tree, bush, vines, or in variety of man-made structures. Clutch 3–5 eggs, usually 4; incubation period 13–14 days; fledging period 10–11 days; family remains on territory for a further 2 months.
Movements. Mostly resident. N breeders (e.g. those on Hokkaido) move S or downslope from end Sept, often arriving in plains or suburbs of cities in large numbers during winter. Migration during daylight, sometimes in large flocks; fairly high numbers migrate through Korea in passage. Non-breeding visitor in E China (Jiangsu S to, probably, Fujian), transient in NE.
Status and Conservation. Not globally threatened. Generally abundant and conspicuous throughout Japan, particularly on smaller offshore islands. Locally common in South Korea, uncommon in Taiwan, common in Philippines. Common in China in non-breeding season. In N Japan (SE Hokkaido), mean number of birds/2 km transect ranged from 0·3 in mixed forest to 0·9 in wooded farmland and 1·0 in residential areas; in Japan, has in recent decades expanded its range into urban areas, where now breeds even in city centres (e.g. Osaka). Considered a pest in Japan because of its habit of feeding on commercial fruit and vegetable crops. Acts as a dispersal agent for seeds of a variety of plants.
Bibliography. Brazil (1991), Chang James Wanfu (1993), Cheng Tsohsin (1987), Collar (2004c), Delacour & Mayr (1946), Dickinson & Dekker (2002b), Dickinson, Dekker *et al.* (2002b), Dickinson, Kennedy & Parkes (1991), duPont (1971), Étchécopar & Hüe (1983), Fujimaki (2004), Fukui (1995, 2003), Gore & Won Pyongoh (1971), Kawakami & Fujita (2004), Kennedy *et al.* (2000), Kurosawa & Askins (2003), Lee Woo-Shin *et al.* (2000), MacKinnon & Phillipps (2000), Matsuo (2004), Meyer de Schauensee (1984), Mishima (1960), Severinghaus (1978), Tomek (2002).



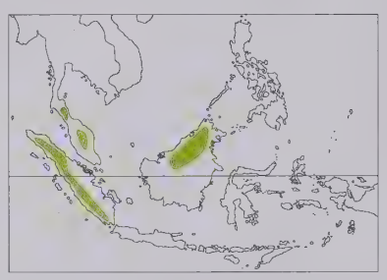
Genus *HEMIXOS* Blyth, 1845

119. **Ashy Bulbul**

Hemixos flavala

French: Bulbul à ailes vertes **German**: Weißkehlbülbül **Spanish**: Bulbul Ceniciento
Other common names: Brown-eared Bulbul(!)

Taxonomy. *H[emixos]. flavala* Blyth, 1845, Nepal.
Sometimes included in expanded genus *Hypsipetes*. Forms a superspecies with *H. cinereus* and *H. castanonotus*, and all often treated as conspecific, but morphological and vocal distinctness of constituent taxa suggests that they are best viewed as allospecies; full review necessary to determine relationship among forms. Isolated race *remotus* is notably divergent, and may warrant elevation to species rank. Five subspecies provisionally recognized.
Subspecies and Distribution.
H. f. flavala Blyth, 1845 – E Himalayas from N India (E from Uttar Pradesh, including S Assam hills) E to SE Tibet, NW Myanmar and S China (W Yunnan), and NE Bangladesh (Sylhet).
H. f. bourdellei Delacour, 1926 – S China (S Yunnan), E Myanmar, NE Thailand and N & C Laos.
H. f. remotus (Deignan, 1957) – S Laos, S Vietnam (S Annam) and SE Cambodia.
H. f. hildebrandi Hume, 1874 – S Myanmar and W Thailand.
H. f. davisoni Hume, 1877 – S Myanmar (N Tenasserim) and SW Thailand.



Descriptive notes. 20–21 cm. Medium-large, dark, conspicuous bulbul, crown feathers often raised into full rounded crest; throat feathers often puffed out. Nominate race has crown dark grey, black lores and moustachial stripe bordering pale brown (tawny) ear-coverts; upperparts grey, tail dark brown with olive margins; wings dark brown, inner remiges and greater wing-coverts broadly fringed bright golden with olive tinge (forming large wing patch); white below, with cold grey breast; iris dark reddish-brown; bill black; legs dark brown or dark reddish-horn, soles yellowish-white, claws blackish-brown. Sexes alike. Juvenile is slightly duller and browner (especially on upperparts), with shorter crest, much duller gold in wing, paler bill. Race *bourdellei* has crown, crest, lores and cheeks black, upperparts browner (less olive), underparts whiter; *remotus* has much paler and browner dark head markings, mid-brown upperparts, brownish-tinged breast; *hildebrandi* is similar but slightly larger, with blackish-brown crest and face markings, brownish-grey upperparts; *davisoni* has rich warm brown crown and warm brown upperparts. VOICE. Song, given throughout year, a variety of simple phrases, mostly short, quick, perky and metallic, interspersed with sharp whistles and weak buzzy notes, usually simple e.g. "skrink-er, rink", with second note markedly lowest and last one marginally highest, but sometimes more complicated and jerky, usually alternating between lower-pitched, weaker note and higher, sharper one, e.g. a squawky "skrink-er, rink-er-rink"; in full song, phrases repeated after very short pauses in rambling monologue, and voice rich enough to sound almost like that of a thrush (Turdidae). Marked regional differences in repertoire. Calls include short, abrupt, twangy buzzes, "kzzp" and "bzier", mixed with range of rich and rather musical chatters.
Habitat. Broadleaf evergreen forest, pine (*Pinus*) forest, bamboo patches, edges and nearby plantations in ravines and foothills; occasionally enters tea plantations in India. Usually at 700–1600 m, sometimes to 2100 m; regularly down to adjacent plains and cultivation in non-breeding season; rarely to sea-level. In Khasi Hills (Meghalaya), in India, confined to highest ridges.
Food and Feeding. Fruit, insects and a variety of other items. Feeds on flowers and fruit of *Leucospectrum* and *Heptapleurum* in Myanmar; also eats nectar (face and forecrown often dusted with pollen) and invertebrates, the latter sometimes caught in aerial sallies. Bold and noisy; in pairs during breeding, forming flocks of up to 30 in non-breeding season. Forages at all levels, but usually in middle stratum or subcanopy. One flock recorded as feeding in a flowering "tea-seed" garden.
Breeding. Breeds Apr–Jul. Reports of male assisting with nest-building and incubation require confirmation. Nest a compact cup-shaped structure, strongly built, composed of grass, dead leaves and (sometimes) bamboo leaves, lined with coarse grass stems, less often a few fern roots and scraps of moss, placed low down (1–2 m above ground) and usually well hidden in thick bush, low tree, bracken or vine tangle; one reported as 12 m up in tree, and others reported in wild citrus tree in open scrubby forest. Clutch usually 3 eggs, sometimes 2, rarely 4; incubation period 13–14 days; nestlings fed by both sexes, no information on nestling period.
Movements. Resident, subject to altitudinal movements.
Status and Conservation. Not globally threatened. Generally scarce and local in Nepal, NE India (e.g. Assam and Meghalaya) and N Myanmar (e.g. Chindwin); regular in forests of NE Bangladesh (Sylhet), and historical reports from E Myanmar suggest that it was fairly common; locally common in N Thailand, sometimes in large flocks; locally fairly common in Laos and Vietnam. First recorded in SE Cambodia (at Dak Dam) in 1997. As most large passerines of SE Asian submontane forests, this species is often hunted by hill tribesmen, but its wide geographical range and its tolerance of heavily degraded habitat suggest that it faces no immediate threat of extinction.

120. **Cinereous Bulbul**

Hemixos cinereus

French: Bulbul terreux **German**: Malaya-Weißkehlbülbül **Spanish**: Bulbul Cinereo

Taxonomy. *I[ole]. cinerea* Blyth, 1845, Melaka, Peninsular Malaysia.
Sometimes included in expanded genus *Hypsipetes*. Forms a superspecies with *H. flavala* and *H. castanonotus*, and all often treated as conspecific, but morphological and vocal distinctness of constituent taxa suggests that they are best viewed as allospecies; full review necessary to determine relationship among forms. Two subspecies provisionally recognized.
Subspecies and Distribution.
H. c. cinereus (Blyth, 1845) – S Thailand, Peninsular Malaysia and Sumatra.
H. c. connectens Sharpe, 1887 – N Borneo.

Descriptive notes. 20·5–21 cm; 27–35 g. Medium-large, arboreal, conspicuous bulbul, elongated and pointed feathers of cap and upper neck often raised as crest, long, erectile chin and throat feathers often puffed out. Nominate race has crown and upper neck ash-brown with prominent pale grey feather tips, indistinct pale grey supercilium; area below eye matt black with fine grey tipping, ear-coverts and side of neck pale brown-grey; upperparts fairly dark ashy brown with low-contrast dull grey tipping; upperwing-coverts as mantle, but with dull grey outer-web edging and tipping; primary coverts, flight-feathers and tail fairly dark ashy brown; chin and throat white, contrasting sharply with face and with uniform dull grey-brown breast and flanks; belly to undertail-coverts whitish; iris dark brown to brownish-red (variation age-related and possibly sex-related); bill black; legs dark greenish-grey to slaty black. Differs from *H. flavala* in much browner and more uniform plumage. Sexes alike. Juvenile is similar to adult, but has less distinct face pattern, duller iris (usually pale cinnamon-brown or greyish-brown), paler legs. Race *connectens* differs from nominate in having less black on face and moustachial area, olive-yellow fringing on wings and tail, and yellow vent and undertail-coverts. VOICE. Regular calls by group-members are a series of loud ringing "tree-tree-tree", a whining "whear", sharp "chiap", and double "wheesh-wheesh" whistle. Song a brief, sweet "beelee-bear beelee burlee", less choppy and metallic than that of *H. flavala*. In Borneo (race *connectens*) thought to be relatively quiet, but has voice similar, a harsh "trrk", low reedy "di-deet di-deet" and low throaty "to to to".
Habitat. Montane broadleaf evergreen forest (primary or selectively logged) and secondary growth. Recorded at 500–2000 m in Sumatra. In Peninsular Malaysia, inhabits submontane zone to recorded maximum altitude of 2000 m, and appears to commute to lowlands on irregular foraging excursions, then frequenting riverine and other tall forest edge, secondary forest, wooded parkland and scrub, down to sea-level; noted also as roosting in open *Phragmites* reedbeds. In Borneo (*connectens*) usually in uplands, but locally resident in lowlands, e.g. Niah Caves (Sarawak); in Maliau basin (Sabah), found in *Agathis* forest and kerangas (low-stature forest on nutrient-poor soils) above 880 m.
Food and Feeding. Fruits, including berries, and seeds; also insects, on Borneo including cicadas (Hemiptera) and crickets (Orthoptera). Recorded items include the "berries" of mass-producing *Lindera pipericarpa*, fruits of understorey *Eurycoma longifolia*, and figs, including non-forest banyans, *Ficus glabella* and *F. sumatrana*; of 25 *Ficus* species studied at Kerau, in Peninsular Malaysia, only one (*F. binnendykii*, mean minimum fruit diameter 7·8 mm) was taken by this species. In Borneo, said to eat many berries, seeds and other fruits, e.g. *Litsea cubica*. Often gregarious, gathering in parties of up to six or more with other bulbuls in fruiting trees; occasionally in loose flocks of almost 20, but a count of almost 100 in Singapore exceptional (several foraging parties likely to have converged). Sometimes attends mixed-species flocks. Forages mainly in canopy, middle storey and edge. Fruits either plucked while bird perched or snatched in brief hovering

flight. Insects plucked from branches, or caught during short aerial sallies, sometimes vertically upwards, from exposed perch.
Breeding. Feb–Jun. One nest was an open cup, placed 3 m above ground in small roadside tree in montane forest. One brood of two fledglings, tended by both pair-members. No other information.
Movements. Resident, with post-breeding dispersive movements. In Peninsular Malaysia, dispersal appears to occur annually, and probably seasonally, but incidence varies, and birds tend not to remain long at any one site; records in lowlands fall between Aug and April, with peak in Sept–Dec, suggesting regular altitudinal migration; influxes reported at low altitudes, down to sea-level, and individuals recorded as far afield as Singapore and even Riau Archipelago (Bintan I). The very few breeding records are from montane zone, and believed that only non-breeders range into lowlands. No seasonal movements described in Borneo and Sumatra.
Status and Conservation. Not globally threatened. Not evaluated. Generally common in mid-montane habitat throughout range, but scarce in N Sumatra. In Peninsular Malaysia, regular and common in uplands, including Fraser's Hill and Cameron Highlands. Said to be abundant in Kelabit uplands of Borneo. Its montane breeding habitat, fairly wide ecological tolerance and mobility imply that this species is still at low risk overall. Occurs within several protected areas, including Kerinci-Seblat National Park, in Sumatra, and at lower levels of Mount Kinabalu National Park, in Borneo.
Bibliography. Büttikofer (1887), Chasen & Hoogerwerf (1941), Davison (1987, 1997a), Dickinson & Dekker (2002b), Dickinson *et al.* (2002b), Gibson-Hill (1949), Holmes (1996), Hume (1878a), Jenkins *et al.* (1996), Jeyarajasingam (1990), Jeyarajasingam & Pearson (1999), Lambert (1989b), Lekagul & Round (1991), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Marsh (1989), McClure (1964, 1966), Medway (1972), Medway & Wells (1976), Rajathurai (1996), Riley (1938), Robson (2000), Smythies (1957, 1999), Tobias & Phelps (1994), Wells (2005), Wells *et al.* (1978).

121. **Chestnut Bulbul**

Hemixos castanonotus

French: Bulbul marron **German**: Hainan-Weißkehlbülbül **Spanish**: Bulbul Castaño
Other common names: Chestnut-backed Bulbul

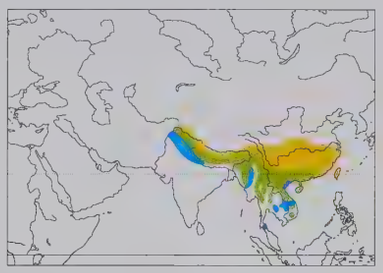
Taxonomy. *Hemixus castanonotus* Swinhoe, 1870, Tai-ping-sze and near Lingmun, central Hainan. Sometimes included in expanded genus *Hypsipetes*. Forms a superspecies with *H. flavala* and *H. cinereus*, and all often treated as conspecific, but morphological and vocal distinctness of constituent taxa suggests that they are best viewed as allospecies; full review necessary to determine relationship among forms. Two subspecies recognized.
Subspecies and Distribution.
H. c. canipennis Seebohm, 1890 – S China (S Hunan, Guangxi, Guangdong, Fujian) and NE Vietnam (Tonkin).
H. c. castanonotus Swinhoe, 1870 – N Vietnam (E Tonkin) and S China (Hainan).
Descriptive notes. 21·5 cm. Medium-sized, noisy, conspicuous bulbul with slightly decurved bill, elongated crown feathers often raised into a crest. Nominate race has forehead chestnut, darkening

to black tinged with reddish-brown on head side and crown; upperparts rich ruddy brown; wings dusky brown, fringed yellowish-green on upperwing-coverts, secondaries and tertials; tail feathers dusky brown, lightly edged greenish-yellow; chin and throat white; underparts whitish, tinged brownish-grey on breast and flanks; iris very dark brown to reddish-brown; bill black; legs black. Sexes alike. Juvenile has much duller head side and upperparts, much paler brown crown, paler and more uniform wings, browner breastband. Race *canipennis* has darker side of head, upperwing-coverts, secondaries and tertials fringed whitish-grey, tail feathers without edging. Voice. Noisy throughout year. Sings with clear, simple, jolly, whistled phrases, e.g. "whi-wi-wu" or "to-to te-wee", usually interspersed with churred notes, often just a simple phrase, at other times semi-continuously from prominent high perch in manner of thrush (Turdidae); quite similar to song of *H. flavala*, but usually thinner and less thrush-like. In flocks, individuals call to each other with harsh single notes.
Habitat. Broadleaf evergreen forest, edges and secondary growth, in hilly lowlands up to 1000 m. Not restricted to tall or mature growth; thrives in brushy ravines and low-stature montane woodland.
Food and Feeding. Eats large quantities of small berries and other fruit; insects and larvae, including caterpillars, also caught, and apparently consumes many moths (Lepidoptera), snatching them in flight after flushing them from hiding places. Often seen in noisy flocks of up to 35 individuals outside breeding season. Probably similar in ecology to *H. flavala*.
Breeding. May–Jul in China; two or more broods. Breeds in territorial pairs. Nest built by female (unassisted?), a deep, compact, cup-shaped structure made from moss, leaves, leaf skeletons, strips of bark and other fibrous material, lined with fine grasses and rootlets, placed at variable height (usually 2–5 m) above ground in fork in tree or bush. Clutch 3 eggs; no information on incubation and nestling periods.
Movements. Generally resident; some movement S in winter. In Hong Kong, where resident population exists, is also an irregular (irruptive) non-breeding visitor Oct–Apr, common in some years, rare in others.
Status and Conservation. Not globally threatened. Often common. Survives even in areas where human population is high. Range seems to be expanding and numbers increasing in some peripheral areas, e.g. Hong Kong. Breeding populations often very densely packed in well-wooded habitats, and numbers remain high near villages and towns.
Bibliography. Caldwell & Caldwell (1931), Carey *et al.* (2001), Cheng Tsohsin (1987), Dickinson & Dekker (2002b), Dickinson *et al.* (2002b), Étchécopar & Hüe (1983), Lewthwaite (1996), MacKinnon & Hicks (1996), MacKinnon & Phillipps (2000), Meyer de Schauensee (1984), Nguyen Cu *et al.* (2000), Robson (2000, 2002c), Stepanyan (1995), Strange (2002), Swinhoe (1870), Webster (1975), Zhang Cizu *et al.* (1997), Zheng Guangmei & Zhang Cizu (2002).

Genus *HYPSIPETES* Vigors, 1831

122. Himalayan Black Bulbul

Hypsipetes leucocephalus



French: Bulbul noir **German**: China-Rotschnabelbülbül **Spanish**: Bulbul Negro
Other common names: Black Bulbul (when treated as conspecific with *H. ganeesa*)

Taxonomy. [*Turdus*] *leucocephalus* J. F. Gmelin, 1789, Guangzhou, Guangdong, south China. Previously included within a broad *H. madagascariensis*. Usually treated as conspecific with *H. ganeesa*, but marked differences in morphology and vocalizations indicate that the two are better considered separate species. Races of present species exceptionally diverse; full review of geographical variation, including adequate sample of recorded songs (not calls), required in order to assess whether more than one species involved. Proposed race *impar* (from Langbian massif, in S Vietnam) treated as a synonym of *concolor*, but may, in view of its geographical isolation, deserve recognition; further study required. Ten subspecies provisionally recognized.

Subspecies and Distribution.

H. l. psaroides Vigors, 1831 – Himalayas from NE Afghanistan (Kunar Valley) and N Pakistan E to NE India (Arunachal Pradesh, also S Assam hills), S Tibet and NW Myanmar; old record(s) in C India.
H. l. nigrescens Stuart Baker, 1917 – NE India (E Assam and Manipur) and W Myanmar (including Chin Hills and Arakan).
H. l. sinensis (La Touche, 1922) – breeds S China (NW Yunnan); non-breeding Thailand, Laos and Vietnam.
H. l. stresemanni (Mayr, 1942) – breeds S China (N Yunnan); non-breeding Thailand and Laos.
H. l. ambiens (Mayr, 1942) – NE Myanmar and S China (Salween watershed, in W Yunnan).
H. l. concolor Blyth, 1849 – E Myanmar, S China (S Yunnan) and Indochina.
H. l. leucothorax (Mayr, 1942) – breeds C China (S Shaanxi, Sichuan, Hubei); non-breeding W, N & E Myanmar, N & NE Thailand, N Vietnam (Tonkin).

H. l. leucocephalus (J. F. Gmelin, 1789) – breeds SE China (S Anhui, Zhejiang and Hunan S to Guangxi and Guangdong); non-breeding E Myanmar and N Indochina.
H. l. nigerrimus Gould, 1863 – Taiwan.
H. l. perniger Swinhoe, 1870 – S China (Hainan); possibly also N Vietnam (E Tonkin).

Descriptive notes. 23·5–26·5 cm. Large, noisy, conspicuous bulbul with expressive, ragged crest, broadly triangular tail notched and splayed somewhat like that of a drongo (*Dicrurus*). Nominate race has all-white head, blackish upperparts, paler on rump; sooty grey below, feathers of belly and undertail-coverts streaked or tipped whitish; iris brown to dark brown, eyelids edged orange; bill deep orange, tinged reddish at base, mouth orange; legs orange, claws horn. Sexes usually alike, female generally smaller than male. Juvenile lacks crest, is dull brown overall, with duller bill and legs, pale grey underparts mottled brownish or greyish (throat and belly whitest, breast darkest), rufescent wing edgings; usually indistinguishable from adult after post-juvenile moult. Race *psaroides* lacks pure white in plumage, is slate-grey throughout, with blackish crown, broad blackish malar bordering paler grey face, whitish-grey central belly, pale-edged undertail-coverts, iris deep chestnut, eyelid black, bill, tongue and legs bright coral-red, claws horn-brown; *nigrescens* is darker blackish-grey above and below, lacks grey patch above lores or behind eye, no contrast between cap and mantle, bare-part colours as previous; *concolor* is even darker, blackish above, with no distinct contrast between cap and upperparts, slightly paler grey below, blackish malar patch; *ambiens* is overall blacker; *sinensis* is very like previous but sometimes quite grey below, occasionally 2–3 white feathers on forehead (possible hybrids), iris deep chestnut, bill and legs bright red; *stresemanni* is similar to nominate (head and breast white), but body entirely blackish-grey, lacking paler grey tones, bare-part colours as nominate; *leucothorax* is inseparable from previous in field, female closely resemble male of previous but slightly smaller; *nigerrimus* is black with conspicuous grey margins on flight-feathers, dark greyish underparts; *perniger* is almost entirely black, but with deep greyish-green gloss on margins of upperpart and underpart feathers (not wings and tail), iris deep chestnut, bill and legs bright coral-red. Voice. Generally noisy, calling semi-continuously when perched or in flight, and often making thin, shrill, nasal, and squeaky sounds; large flocks emit continuous shrill, nasal, chattering babble. Calls include variety of rather high-pitched, somewhat weak, nasal but sharp, staccato "nyurk" and "nurrit" notes, often quickly repeated and subdued in more conversational versions, occasionally interspersed with nasal downslurred squealing mews, "nyeeer", or upslurred "hwiiii", these sometimes doubled. Short nasal "nyerk", "nyer-wick" and "nyack" notes in flight. Songs, by solitary males repetitively from treetops, include shrill, very nasal, twangy "snyur-khwit, snyurt"; also clanging, squeaky, bell-like "skyurt-vee-yurt", first note screechy and nasal. Likely that regional differences exist.

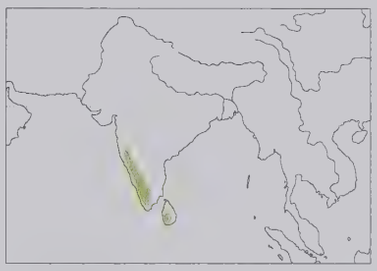
Habitat. Broadleaf evergreen and mixed deciduous forest, groves, clearings and edges, visiting more open forest in winter. In Pakistan, typically associated in breeding season with oak (*Quercus incana*) and pine (*Pinus roxburghi*) forest; in much of breeding range, prefers tall broken forests of oak, pine and rhododendron, sometimes entering mature gardens; usually in mid-montane zone at 600–2100 m, rarely to 3200 m, and breeding at lower foothills in only a few locations (e.g. Royal Chitwan National Park, in Nepal). Outside breeding season, occurs in evergreen and mixed deciduous lowland forests, montane forest and secondary growth, on slopes at all elevations, mainly above 500 m; wanders sporadically to plains (down to c. 100 m) in response to bad weather or fruiting events; vagrants recorded close to sea-level.

Food and Feeding. Diet mainly berries and other fruits, also flower nectar and insects. In Pakistan, thought to subsist largely on berries of *Viburnum foetens* and other shrubs during winter, but largely insectivorous in breeding season; in N Pakistan and Kashmir, berries of "Persian lilac" (*Melia azedarach*) a staple food, along with figs (*Ficus religiosa* and *F. bengalensis*). Figs (including *F. nitida*) make up a large part of the diet in Hainan and Taiwan. In N Myanmar, birds (of both white-headed and black-headed races) were seen to feed on fruits and flowers of, among others, *Prunus*, *Ficus*, *Callicarpa arborea*, *Embelia*, *Maesa*, *Heptapleurum*, *Leucospectrum*, and on insects attracted to these; *Leucospectrum* (especially its nectar) was apparently a very common foodplant. Individuals or groups regularly gather at flowering trees or shrubs to eat nectar, e.g. at rhododendrons (in Himalayas) and at trees such as *Cassia*, *Bombax* and *Salmalia malabarica*; in Himalayan spring, seen to eat deciduous leaf and flower buds. Well known as a skilled catcher of insects, especially in aerial sallies from treetops. Seems to favour beetles (Coleoptera), but one observed to catch and consume a large green mantid in Pakistan, and others seen catching hymenopterans or dipterans attracted to large flowers such as *Butea monosperma* or *Rhododendron arboreum*. Gregarious. In non-breeding season, can gather in large flocks of up to 100 individuals, sometimes several hundreds; at this time white-headed races sometimes mix freely with black-headed ones, but the two usually keep to separate flocks. Usually forages in upper branches of tall trees, often perching directly on top of canopy; rarely descends to undergrowth and never to ground.

Breeding. Breeds Apr–Jul. Nest a neat shallow cup, described variously as flimsy and as relatively large and robust, made of roots, twigs, bamboo leaves and bark, covered and fastened together with cobweb, interwoven with pieces of moss and leaves, lined with fine material such as coarse grass stems, bark shavings, pine needles, mammalian hair and the like; nest material depends on habitat, in Kashmir (*psaroides*) usually a foundation of dead leaves and dried grass, walls of stalks and twigs well plastered with spider webs, sometimes much moss used, and in Taiwan (*nigerrimus*) constructed from bamboo leaves and twigs, covered on outside with moss and spider webs, lined with pine needles and very fine stems and leaf stalks; placed on bough or in fork of bush or tree, including conifer, 2–15 m above ground but usually fairly high (7–10 m), most nests slung between two slender branches that fork horizontally, often near end of horizontal branch, a small minority lodged in upright fork; reported tendency to nest in single tree narrowly isolated from forest. Clutch 2–3 eggs, rarely 4–5; incubation mostly (probably entirely) by female, male sings near nest for much of day; no information on incubation and nestling periods.

Movements. Some races resident, others migratory. Migration patterns complex; species usually erratic in occurrence, depending on food supplies, even where essentially resident (e.g. N Thailand). White-headed races (nominate, *leucothorax*, *stresemanni*) generally migratory, probably travel greatest distances; common non-breeding visitors to NE Myanmar, and unknown races occur in winter S to N Thailand and sometimes farther S (*leucothorax* a vagrant in S Thailand); one record for Bangladesh, thought to have involved *stresemanni*. In Laos, numbers of resident black-headed race (*concolor*) augmented by influx of black-headed and white-headed winter visitors (the latter more common); both types have been recorded in small numbers in Cambodia in winter. Individual of unknown race has occurred in N Peninsular Malaysia. White-headed individuals seen during summer on Taungyi crag, in Shan States of Myanmar, prompting suggestion that they may breed that far S, but this seems unlikely. Tends to migrate back to breeding quarters in Mar–May. In addition, seasonal altitudinal migrations undertaken in N Pakistan, Kashmir, Himachal Pradesh and elsewhere in Himalayas, some individuals moving farther afield, into plains of Pakistan and India.

Status and Conservation. Not globally threatened. Generally fairly common to very common. Race *psaroides* fairly common in N Pakistan, N India and much of Nepal; *perniger* common on Hainan; white-headed races common in parts of China. This species' tolerance of degraded habitats suggests that deforestation poses no serious threat to its future survival.



Bibliography. Ali & Ripley (1996), Ali *et al.* (1996), Bailey (1915), Bates & Lowther (1952), Caldwell & Caldwell (1931), Carey *et al.* (2001), Chang James Wanfu (1993), Cheng Tsohsin (1987), Cock & Marshall (1873), Collar (2004c), Cook (1912), Currie (1916), Daltry & Momberg (2000), Davidson (1998), Deignan (1945), Delacour & Jabouille (1931), Dickinson & Dekker (2002b), Dickinson *et al.* (2002b), Duckworth & Hedges (1998), Duckworth, Salter & Khounboline (1999), Étchécopar & Hüe (1983), Fulton (1904), Grimmett *et al.* (1998), Harington (1909a), Hingston (1921), Hopwood (1912), Hüe & Étchécopar (1970), Hume (1872–1873, 1888), Hume & Davison (1878), Inskipp & Inskipp (1991), Inskipp *et al.* (2000), Jones (1919), King *et al.* (2001), La Touche (1898), Lekagul & Round (1991), Lewthwaite (1996), MacKinnon & Phillipps (2000), Magrath (1908, 1909), Mahabal (1992), Mayr (1942), Mears & Oates (1907), Medway & Wells (1976), Meyer de Schauensee (1984), Paludan (1959), Perreau (1910), Prater (1923), Rattray (1905), Riley (1938), Rippon (1901), Roberts (1992), Robinson & Kloss (1919a), Robson (2000), Robson *et al.* (1998), Scully (1879), Smythies (1986), Stanford & Mayr (1940–1941), Stepanyan (1995), Stevens (1923–1925), Stuart Baker (1892–1893), Swinhoe (1863), Thompson & Johnson (2003), Ticehurst (1933), Traylor (1967), Ward (1906–1908), Webster (1975), Wells (2005), Whistler (1918), Whitehead (1910–1911), Wickham (1929–1930), Zheng Guangmei & Zhang Cizu (2002).

123. Square-tailed Black Bulbul

Hypsipetes ganeesa

French: Bulbul des Ghats **German**: Indien-Rotschnabelbülbül **Spanish**: Bulbul de los Ghats
Other common names: Black Bulbul (when treated as conspecific with *H. leucocephalus*)

Taxonomy. *Hypsipetes Ganeesa* Sykes, 1832, "Dense woods of the Ghats" = Mahabaleshwar, India.
Previously included within a broad *H. madagascariensis*. Usually treated as conspecific with *H. leucocephalus*, but marked differences in morphology and vocalizations indicate that the two are better considered separate species. Further, morphological distinctions between nominate race and *humii* minor, but vocal differences seem substantial; further study needed in order to determine whether two species involved. Two subspecies provisionally recognized.
Subspecies and Distribution.
H. g. ganeesa Sykes, 1832 – Western Ghats of India S from Bombay (including Shevaroys).
H. g. humii (Whistler & Kinnear, 1932) – Sri Lanka.

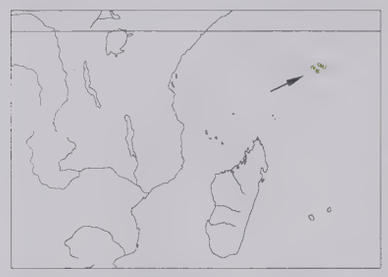
Descriptive notes. 21–24 cm. Large, noisy, conspicuous bulbul, appearing generally dark sooty grey, with very short crest, square-tipped tail. Has glossy black head, greenish sheen when plumage fresh; cheeks and ear-coverts slaty brown; upperparts dull bluish-slate, centres of back feathers especially dark; wings and tail dull brown, wing-coverts, secondaries, innermost primaries and base of rectrices edged bluish-ash; chin fairly dark; throat, chest and underparts faded slate-grey, palest on belly; undertail-coverts slaty brown with dark shafts and whitish edges; iris reddish, hazel, or orange with dusky tinge (sometimes slightly brownish); bill bright red, tinged orange; legs yellowish-red, claws blackish. Sexes alike. Juvenile is browner, paler below, flight-feathers and tail feathers fringed pale tawny, also has duller legs, yellowish-brown iris, blackish marks at bill tip and around nostril. Race *humii* is noticeably larger than nominate, also fractionally paler, with distinctly larger bill. Voice. Often calls from exposed treetop branches, or in flight, voice much harsher and less nasal than that of *H. leucocephalus*, but races differ considerably from each other; nominate has higher-pitched, harder, shriller vocalizations, those of *humii* noticeably lower and more guttural. Songs (nominate) include slow, high-pitched, strident, shrill "chur-chik-chik!" and similar variants with 2–5 notes, e.g. "chik!-chur-chik!"; also longer versions, sometimes with melodious, throaty, almost warbling notes, e.g. "kluk-kluk, takluk", and sharp "seep" notes appended. Songs of *humii* include steady, squawky, guttural strophes of chortling screeches, and longer versions with a few thinner more metallic notes admixed; also short raspy gurgles (e.g. "schurt, schew-pits"), sometimes with final note stressed (e.g. "skurt-skyewéé!"), first note quick and squawky, other two thin, squeaky and metallic. Calls include prolonged harsh mewing that descends only slightly; rapid, raspy, chuckling series, gradually slowing and becoming more strident; and harsh, often doubled "chyerk" notes, lower, harder and less nasal than those of *H. leucocephalus*.

Habitat. In India occurs in wide variety of forest types, including heavily degraded forests mixed with plantations; usually at 1000–2600 m, sometimes descending to 500 m when not breeding. In Sri Lanka, race *humii* occurs in similar habitats in Wet Zone lowlands and adjacent mid-altitude hills, to at least 1600 m; seasonally into Dry Zone or up to higher altitudes.

Food and Feeding. Fruits and seeds; berries include *Ziziphus*, *Eugenia*, *Vaccinium*; also insects. In S India, visits flowers of *Erythrina*, *Loranthus* and others, including introduced *Grevillea* and *Eucalyptus*, for nectar and insects. Often in mixed flocks (including species of *Zosterops*, *Sitta*, *Garrulax*, *Muscicapa* etc.), or in monospecific flocks of 20–30 (sometimes hundreds) in non-breeding season. Takes insects from foliage and branches; sometimes sallies after flying insects. Occasionally clings to large vertical trunks or branches.

Breeding. Feb–May and Jul–Sept in Sri Lanka and Mar–Jun in India; at least two broods. Nest in Sri Lanka described as a small and untidy cup, made of dead leaves, roots and mosses, lined with fine fibres, placed well up (usually 5–8 m) and fairly well concealed in forking branch of tree, apparently regularly in one narrowly isolated from main forest; nest in India small for size of bird, composed principally of moss, amply lined with fine grass and moss rootlets, placed against side of

On following pages: 124. Seychelles Black Bulbul (*Hypsipetes crassirostris*); 125. Reunion Black Bulbul (*Hypsipetes borbonicus*); 126. Mauritius Black Bulbul (*Hypsipetes olivaceus*); 127. Madagascar Black Bulbul (*Hypsipetes madagascariensis*); 128. Comoro Black Bulbul (*Hypsipetes parvirostris*); 129. White-headed Bulbul (*Cerasophila thompsoni*).



stout branch, supported by a few thin twigs, or in branches of dense parasitic plant in canopy of acacia (*Acacia*) or other tree. Clutch 2 eggs, sometimes 3; no information on incubation and nestling periods.
Movements. Essentially resident, although erratic wandering and regular altitudinal migration in India. Tends to vacate wettest slopes during heaviest of the SW monsoon (e.g. May–Oct, and especially Jul–Aug). In the Nilgiris (S Western Ghats) occupies higher altitudes in Mar–Jun, descends in Jul–Dec, and large scattered flocks of several thousands of individuals seen migrating in Jul; in same area, reported also as undertaking daily altitudinal movements in large numbers.
Status and Conservation. Not globally threatened. Common and conspicuous in much of Sri Lanka (especially at higher altitudes) and likewise in S portion of Western Ghats. Common in the Nilgiris, where it occurs in variety of reserves, and also in the Periyar National Park. An old record from C India (Berar) should be treated as provisional. This species' survival in small forest fragments, combined with its mobility, suggests that it is unlikely to be immediately threatened by deforestation.

124. Seychelles Black Bulbul

Hypsipetes crassirostris

French: Bulbul merle **German**: Dickschnabelbülbül **Spanish**: Bulbul Picogordo
Other common names: Seychelles/Thick-billed Bulbul

Taxonomy. *Hypsipetes crassirostris* E. Newton, 1867, Mahé, Seychelles Islands.
Sometimes considered to form a superspecies with all other members of genus, and in the past all have been treated as conspecific. Monotypic.
Distribution. Seychelles: Mahé, Praslin, La Digue and Silhouette, and a few neighbouring islands.

Descriptive notes. 24–25 cm; mean 79·5 g (estimated mean for male 83·2 g, for female 74·7 g). A large, chunky bulbul with conspicuous heavy bill, loose, pointed crown feathers often raised to form shaggy crest. Top of head black, slightly glossy; lores blackish, mottled olive-green, cheeks, ear-coverts and side of hindcrown from above rear of eye scaly olive; upperparts olive-brown, variably fringed olive-green (faintly mottled appearance); wings olive-brown, flight-feathers narrowly edged greenish; tail olive-brown, terminally fringed narrowly dirty white, fringes wider (c. 3 mm) on outer feathers than on inner and white extending some way up inner webs on outer feathers; throat and underparts paler olive, feather bases darker on chin and upper throat (appearing more scaly), fading to yellowish in centre of upper belly and undertail-covert feathers, yellowish-white on lower belly, lower flanks washed brownish; iris reddish-brown; bill bright orange; legs bright orange, dark yellow or yellowish-brown. Sexes alike, female on average smaller than male. Juvenile has flight-feathers chestnut, crown feathers fringed dark olive-green, eye yellow-brown, bill blackish and legs dark brown. Voice. Highly vocal. Song, usually by one member of pair from prominent perch, a series of clucks, squawks, whistles and chatters of variable structure and duration. Calls include a cluck, usually singly, sometimes repeated, given mostly immediately upon take-off, apparently as contact when moving between trees; a raucous, bleating "nyeer" ("cat call"), often at intervals of 5–10 seconds, usually by isolated bird separated from other group-members and frequently answered; and rapid "ak-ak-ak-ok-ok-ok" chatter, often lasting for more than 30 seconds, usually in chorus by pair, sometimes family group, often provoking similar response from neighbouring groups and thought to have territorial function. Juvenile may give soft "twee-twee-twee" as begging call.
Habitat. Woodland and forest, including secondary and introduced formations of almost all types. Found virtually wherever fruiting trees and bushes occur, including near habitation where cover present; rare in towns and in lowlands of Mahé, particularly in areas dominated by coconuts. At all altitudes; to 914 m on Morne Seychellois, the highest point in Seychelles.
Food and Feeding. Fruit, flowers, arthropods, bird eggs; possibly nectar. One study documented 22 species of hard and soft fruit, including native genera *Deckenia*, *Dillenia* and *Phoenicophorium* and exotic *Artocarpus*, *Ceiba*, *Cinnamomum*, *Ficus*, *Mangifera*, *Psidium*, *Rubus*. Athropods include mantids, cicadas (Cicadidae), caterpillars, hymenopteans (ants, wasps), orthopterans and spiders (Araneae). Gregarious, occurs in pairs, family groups or small parties; up to 15 may gather at fruiting trees. Forages mainly in crowns of trees and bushes, rarely in understorey. Gleans insects from branches and trunks, probes in leaf clusters; snatches large insects from branches or large leaves in swooping flight, and acrobatically catches winged insects in flight. Also pulls apart tangles of dead leaves, flying down to catch dislodged insects in mid-air; reluctant to retrieve from ground. Will descend to ground to eat contents of large fruit broken by fall. Aggressive, with frequent chasing.
Breeding. Recorded in Sept–Jan wet season, occasionally in other months; birds in breeding condition in Jul and mating in Sept. Territorial, territory defended against conspecifics and most other birds by pair or by group of three or more; role of additional individual(s), which often (but not always) immature, unclear, but during nest-building stage pair sometimes tolerates and feeds with a third bird, although latter does not approach nest. Nest built either by one member of pair, the other staying close by, or by both sexes in early stages and then by one, assumed to be female, which incorporates material brought by mate, construction takes 6–10 days; roughly circular, made of strips of grass up to 20 cm long, dead leaves in base and lower part of outer walls, palm fibres, small twigs, bark fragments, moss and pieces of creeper, lined with coarse fibres such as *Casuarina* needles, external diameter 13 cm, depth 8 cm, internal diameter 9 cm, cup depth 4–5 cm; mostly well above ground, to 15 m, once at 2 m, attached to support by cobwebs, usually in branch fork of forest tree, mostly large-leaved one (e.g. *Terminalia catappa*, *Tabebuia pallida*, *Sandoricum indicum*), but typically where no foliage and hence very exposed. Clutch 2 eggs, rarely 3; incubation mostly by female, some observations indicating that male may incubate for an hour or so each day, period c. 15 days; chicks brooded by both parents at least initially, nestling period 21 days; young reportedly fed by adults for one week after fledging, although other observations indicate that begging juveniles ignored or chased off. Likely that usually only one chick survives; in one study, 92 of 109 juveniles with parents in Sept–Oct were single young, although possibility of very rapid dispersal away from natal territory, perhaps by one sex, was not ruled out.
Movements. Sedentary. Three colour-ringed individuals observed very close to ringing site almost one year later; no movements of more than 200 m recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Granitic Seychelles EBA. Generally common and widespread. Has adapted well to anthropogenic habitat modification. Occurs in several protected areas, including Praslin and Morne Seychellois National Parks and La Digue Special Reserve; estimated population in Praslin National Park and surrounding areas 200–500 pairs, in Mahé highlands and surrounding areas (including the national park) 1700–2300 pairs, on La Digue I 2000–4000 pairs and on Silhouette I 500–2700 pairs.

125. Reunion Black Bulbul

Hypsipetes borbonicus

French: Bulbul de Bourbon **German**: Reunionbülbül **Spanish**: Bulbul de Reunión
Other common names: Reunion Bulbul/Merle

Taxonomy. [*Turdus*] *Borbonicus* J. R. Forster, 1781, Réunion Island.
Sometimes considered to form a superspecies with all other members of genus, and in the past all have been treated as conspecific. Was often thought to be conspecific with *H. olivaceus*, but differs in behaviour, voice and eye colour; treatment as a separate species supported by recent molecular studies. Monotypic.
Distribution. Réunion.

Descriptive notes. c. 22 cm; male 51 g, female 57·2 g, unsexed 43–56 g. A medium-large grey-brown bulbul with pale eye, long orange bill, and loose and erectile pointed crown feathers. Top of head is glossy black, sharply demarcated from nape and hindneck, which are greyish-olive with some browner streaking, lores black, cheeks, ear-coverts and side of hindcrown behind eye grey, ear-coverts with darker shaft streaking; upperparts dark greenish-olive, streaked brownish, rump washed cinnamon, tail dark olive-brown; wings olive-brown, secondaries and tertials fringed greenish-grey; chin black, throat and breast dark grey, flanks dull greenish-grey, upper belly yellowish-grey, lower belly dirty yellowish, lower flanks pale cinnamon, undertail-coverts dirty yellowish with cinnamon wash; iris white or creamy; bill and legs yellowish-orange. Sexes alike, female thought to be smaller on average than male. Juvenile has body plumage paler, primaries and tail feathers rusty. Voice. Four main types of vocalization recognized, a "chuckle", a "cat call", a stress "kek" and soft notes of pair contact; repertoire generally resembling that of *H. olivaceus* but differing in detail. Song, commonly in early morning and at intervals during day, often from high perch, loud, fairly short and monotonous, consists of various chuckle phrases strung together; shorter chuckle elements, sometimes combined with cat calls, often given by both members of pair, whether close to each other or some distance apart. Cat call (or "mew") a long drawn-out nasal, wheezy note, initially slightly ascending and then descending; "kek" seems to be given in situations of fear and aggression, as when being mobbed. Loud, ascending whistle also reported.
Habitat. Mixed evergreen forest, to lesser extent also degraded forest and native *Acacia heterophylla*-dominated forest, at 300–2500 m, occasionally as low as 100 m; below 1800 m only in patches of native mixed forest on slopes of ravines and canyons. Breeding largely confined to native forest, at 500–1800 m. Avoids heath vegetation, cultivated areas and gardens.
Food and Feeding. Mainly frugivorous; flowers, nectar and some insects also taken. Native fruits include, in particular, *Aphloia theiformis*, also *Acanthophoenix*, *Allophylus*, *Ficus*, mistletoe (Loranthaceae) and possibly *Sideroxylon*; introduced fruits such as guava (*Psidium guajava*) and strawberry guava (*P. cattleianum*). Flowers and buds of *Nuxia* and eucalyptus (*Eucalyptus*) are eaten, and nectar of latter also taken. Only few records of clumsy flycatching from a perch and equally maladroit "leap-snatching" of insects from trees; seems less insectivorous than are congeners in Malagasy Region. Occurs singly, in pairs or in small family groups; more than one pair may congregate at a food source, and at lower elevations forms noisy groups of 4–10 (usually 3–6) individuals, perhaps family parties. Forages mostly in middle strata, only rarely descending to the ground to collect fallen fruit. Generally silent, with occasional spells of interaction; very shy, flies off noisily when disturbed.
Breeding. Nesting recorded in Jul–Feb, coinciding with dry season and start of rains; recent fledglings in Feb and juvenile in Mar; possibly double-brooded. Nest an untidy cup, built of stems and leaves of ferns, mosses and rootlets, in small tree or bush. Clutch 2–3 eggs; no information on incubation and fledging periods.
Movements. Seasonal altitudinal migration recorded. Post-breeding movement to lower elevations in Feb–Aug, possibly in response to decreased food supply in upland forests during austral winter; returns to higher elevations to breed in Aug–Feb. Situation not clear, however, since movement to higher altitudes in Jul–Aug has been reported to be associated with ripening of fruit (in particular, the guava crop); corresponding movement down towards coastal areas in Dec–Mar, again reputedly to coincide with guava fruiting season. Some individuals found at high altitudes all year. Further study required.
Status and Conservation. Not globally threatened. Restricted-range species: present in Réunion EBA. Uncommon; most frequent in native mixed evergreen forest. Was considered "extraordinarily abundant" in the past, but numbers greatly reduced by hunting. In 1973–74, mean density estimated at 25 pairs/km² within breeding distribution of c. 1000 km², giving total population of c. 25,000 pairs; in 1980–81, however, much lower total of 20,500 individuals estimated. Until 1989 this species was officially classed as game, and could be legally hunted for about two months per year; it was widely shot outside this period, however, and was also caught illegally by liming. Now fully protected by law, and numbers thought to be increasing as a result. Appreciated as a songster; illegal capture for the local cagebird trade is the biggest current threat. Parts of its population are protected in La Roche Ecrite Nature Reserve and Grand Bénard Protected Biotope. Still very shy of humans, as a consequence of hunting.
Bibliography. Barré (1983), Barré *et al.* (1996), Berlioz (1946), Cheke (1987b), Cheke & Jones (1987), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Gregory (2000), Horne (1987), Newton (1876), Sargeant (1992), Sinclair & Langrand (1998), Stattersfield *et al.* (1998), Staub (1976), Warren (2003).

126. Mauritius Black Bulbul

Hypsipetes olivaceus

French: Bulbul de Maurice **German**: Mauritiusbülbül **Spanish**: Bulbul de Mauricio
Other common names: Mauritius Bulbul, Mauritius Merle

Taxonomy. *H[ypsipetes]. olivacea* Jardine and Selby, 1837, Mauritius.
Sometimes considered to form a superspecies with all other members of genus, and in the past all have been treated as conspecific. Was often thought to be conspecific with *H. borbonicus*, but differs in behaviour, voice and eye colour; treatment as a separate species supported by recent molecular studies, which also indicate that it is sister to *H. madagascariensis*. Monotypic.
Distribution. SW, C & SE Mauritius.

Descriptive notes. 25–27 cm; male 69 g, female 76 g, unsexed 70 g and 79 g. A large bulbul with conspicuous pinkish-orange bill, loose and pointed erectile crown feathers. Forehead is olive grey-green, streaked darker, crown and nape very dark olive-green to blackish, slightly glossy; lores blackish, cheeks, ear-coverts and side of hindcrown above mid-point of eye greenish olive-grey; hindneck dull olive grey-green, streaked darker, upperparts dark greenish-olive, streaked brownish, rump slightly browner and warmer; tail and wings olive-brown, secondaries and tertials narrowly fringed greenish-grey; throat, breast and flanks dull dark greenish-grey, belly yellowish-grey, rear flanks pale cinnamon, undertail-coverts dirty yellowish with brownish feather centres; iris dark red-brown; bill pinkish-yellow or orangey, usually darker distally on distal culmen and on cutting edges; legs yellowish-orange or pinkish. Sexes alike, female on average smaller than male. Juvenile moults soon after fledging, then resembles adult but very dingy greyish-brown (lacking bright chestnut remiges of young *H. crassirostris*), with dark, dull bare parts. Voice. At least four types of call recognized, a "chuckle", a "cat call", a stress "kek" and soft notes of pair contact, similar to repertoire of *H. borbonicus*. The chuckle, "chuck chuck", varies seasonally, sexually and with context, but forms basis of simple song, given morning and evening by territorial male, and used for recognition or greeting between pair-members, e.g. by female after a call sequence when rejoining mate or foraging group. Cat call a rather long, clearly defined, raucous "nyeer"; "kek" apparently given in situations of fear and aggression, as during interspecific and intraspecific interactions. Foraging pair utters soft, short chuckles, as do members of group at common food source, suggesting that pair-members maintain contact when in group; on rejoining after some time apart, both also chuckle jointly.
Habitat. Humid forest dominated by native trees, including areas where canopy broken or forest heavily invaded by exotic plants; also uses entirely exotic vegetation where favoured food plants occur, and may travel widely to visit such plants. Mainly between 200 m and 824 m (highest point of island), often lower, and occasionally at sea-level. Core of distribution coincides with upland wet forest, but lowland dry forest also used; exploits wooded valleys of S plateau (containing mostly exotic vegetation). Any area with native or favoured exotic trees over a large part of the S & C part of island may be visited occasionally, perhaps seasonally. Avoids native dwarf forest; generally absent from pine (*Pinus*) and eucalyptus (*Eucalyptus*) plantations.
Food and Feeding. Fruit, arthropods, small vertebrates; occasionally flowers and nectar. Diverse range of native and introduced fruits taken. Native species include *Aphloia*, *Calophyllum*, *Protium*, *Syzygium*, *Warneckia* and an unidentified palm; naturalized exotics include *Apodytes*, *Artocarpus*, *Flacourtia*, *Lantana*, *Ligustrum*, *Litsea*, *Melia*, *Michelia*, *Ossaea*, *Psidium* and *Rubus*. Also takes grapes, apples, papaya, mulberries, raspberries and cherries. Flower-feeding recorded on exotic *Ipomoea* and native *Nuxia*; one observation of nectar-feeding on exotic rose-apple (*Syzygium jambos*). Most animal items taken are arboreal insects: stick-insects (Phasmida), orthopterans (bush-crickets), cicadas (Cicadidae), lepidopterans (adults and caterpillars) and dragonflies (Odonata). Native diurnal geckoes (*Phelsuma*) account for 30% of animal items identified and may, because of large size, constitute a high proportion of biomass eaten. Usually found singly, in pairs, or in (probably family) groups; up to eight seen together. Strictly arboreal; extremely rarely collects food from ground. Animal prey caught by gleaning from leaf bases, twigs and branches, and clumsy flycatching; also crashes into dense foliage and sallies after small insects flushed. Larger items held in bill and immediately beaten against branches.
Breeding. Nesting recorded Nov–Feb; probably single-brooded. Monogamous. Co-operative breeding possible based on third bird feeding young at one nest. Traditional territory may be reclaimed from year to year, vigorously defended by both partners; male frequently gives aerial display to mate, using rapid, exaggerated wingbeats, with tail raised and slightly fanned, while giving a series of "chuckle" notes with head thrown back. Nest built by female (one nest only), a coarse cup made of twigs, coarse grass, leaves, roots(?), moss and lichens, lined with finer material, external diameter 13–23 cm, placed 2–9 m above ground on horizontal branch in low bush or tree, often Japanese red cedar (*Cryptomeria japonica*) where available; territory c. 1 ha around nest. Clutch 3 eggs, in one case completed in 4 days (first and second eggs laid 2 days apart); if clutch lost, repeat laid 8–9 days later in new nest; incubation, by presumed female only, 15–16 days; chicks brooded by presumed female only, fed by both parents, once also by third individual (probably immature?), nestling period 3 weeks; family-members may remain together once young feeding independently. Success poor; fledged broods of one, less often two, juveniles rarely seen; signs of failure consistent with attacks by introduced black rats (*Rattus rattus*) or crab-eating macaques (*Macaca fascicularis*).
Movements. Largely resident; often absent from breeding territories outside nesting season, and may appear in widely scattered localities.
Status and Conservation. VULNERABLE. Restricted-range species: present in Mauritius EBA. In 1993, population estimated at 280 (225–340) pairs in simple census, and total area of occupancy 78 km². Densities extremely low compared with other Malagasy members of genus; generally fewer than 10 pairs/km², possibly reaching 15 pairs/km² in few localities; home range up to 50 ha. Dependent on woody vegetation that provides fruit and animal food; such vegetation currently largely native, and long-term decline caused by destruction of this habitat. Main threat is continued habitat degradation resulting from spread of exotic plants poor in food. This species' populations may be limited by nest predation by non-native mammals and by resource competition with exotic birds, including Common Myna (*Acridotheres tristis*) and *Pycnonotus jocosus*, and mammals. Occurs in Black River Gorges National Park, as well as in number of nature reserves and mountain reserves, the latter aimed at watershed protection; some areas of critical habitat, however, are not included in any form of protected area. Introduced in Diego Garcia (Chagos Archipelago), but now extinct there.

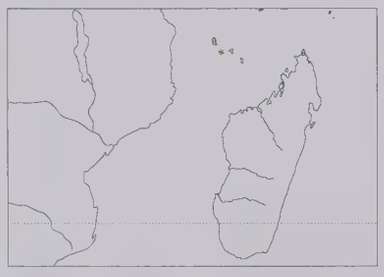
127. Madagascar Black Bulbul

Hypsipetes madagascariensis

French: Bulbul de Madagascar **Spanish**: Bulbul Malgache
German: Madagaskar-Rotschnabelbülbül
Other common names: Madagascar/Black Bulbul

Taxonomy. *Turdus Madagascariensis* Statius Muller, 1776, Madagascar.
Sometimes considered to form a superspecies with all other members of genus, and in the past all have been treated as conspecific. Recent molecular analysis indicates that present species and *H. olivaceus* are sister-taxa; also that populations of Madagascar and Comoros (nominate race) form a monophyletic group, sister to race *rostratus*. Birds from Grande Glorieuse I described as race *grotei*, largely on basis of putative differences in bill size and colour, but not satisfactorily distinguishable from nominate, as any slight differences appear to involve individual, not geographical, variation. Two subspecies recognized.
Subspecies and Distribution.
H. m. madagascariensis (Statius Muller, 1776) – Comoros (all four main islands and some islets), Glorieuse Archipelago (Grande Glorieuse I) and Madagascar.
H. m. rostratus (Ridgway, 1893) – Aldabra.

Descriptive notes. c. 24 cm; male 39–52 g, female 33–52 g. A medium-large, long-tailed, dark grey bulbul, pointed and loose crown feathers often raised to form shaggy crest. Nominate race has top of head and nape black with dark green wash, glossy; lores, preorbital area and narrow line extending back from rear of eye black, indistinct grey supercilium behind eye, dark grey cheeks and ear-coverts; many individuals have faint grey supraloral spot; upperparts dark slate-grey, shaft and centre of feathers brownish; tail dark grey-brown; wings dark brown, secondaries, tertials and greater wing-coverts narrowly fringed grey; chin often dark, throat and underparts dark grey, somewhat paler on flanks, pale grey-white in centre of belly, undertail-coverts grey with pale fringes; iris dark brown or dark red; bill orange, often with dark tip and distal part of culmen; legs dull horn, dull orange-brown, dull yellowish-orange or pinkish. Sexes alike, female on average smaller than male. Juvenile has crown feathers dull, not glossy black, intermixed brownish, back tinged brown, flight-feathers, wing-coverts and margins of tail feathers rusty. Race *rostratus* is longer-legged than nominate, black on head extends only to hindcrown (not nape), upperparts and flanks washed brownish, breast also washed brown, belly centre buffy with slight olive tinge. Voice. Highly vocal; calls varied but unmelodic. Common element a brief nasal, disyllabic, penetrating, downward-inflected "tireet" or "tyeeu", often by several individuals together (perched or in flight), and extended, sometimes with other notes, into conversational 3-note "tireet teetee tireet", "thci-churr-tchi" or "choo-chee chili". Also characteristic single nasal mewing (the "cat call" or "bleat"), "eeeee", "eee-ew", "nyeeea" or "meu", often hard to locate. Some inter-island variation in harmonic frequency of cat call noted in Comoros; birds on Mohéli have distinct song type (not noted elsewhere in Comoros), in which song is cut across with short, clear, abrupt whistled "tju"; Glorieuse population also reportedly exhibits some vocal differences from that on Madagascar. Race *rostratus* has similar repertoire, based on loud, clear "cheep" or "chip" sounds, commonly consisting of 2 notes, second lower than first, sometimes extending to 3 or 4 notes, the final two still lower in pitch; also rapid series ending in louder and higher single note, a harsh alarm call "yeeah", and a grating "keeeoo", resembling closely mewing call of nominate.
Habitat. Forest of all types, secondary growth, sparsely wooded savanna, orchards, plantations, scattered trees in agricultural fields, urban parks and around habitation. In primary forest in Madagascar, confined to edge habitats in some places, penetrates deep into forest interior in others; sea-level to 2500 m. In Comoros, commonest on Grand Comoro (Njazidja) in coastal areas but found to 700 m (occasionally 1000 m) on Mt Karthala and to 800–900 m on La Grille; to 400 m on Mohéli (Mwali), where also most abundant around coast; at higher altitudes on both islands replaced by *H. parvirostris*; on Anjouan (Ndzuani) and Mayotte (Maore), where *H. parvirostris* absent, found to 1100 m and summit (600 m), respectively. Occurs throughout Aldabra wherever trees and scrub present, but less common in mangrove.
Food and Feeding. Fruit, also flowers and seeds; also arthropods, including hymenopterans (ants, wasps), ant-lions (Myrmeleonidae), beetles (Coleoptera), bugs (Hemiptera), cicadas (Cicadidae), grasshoppers (Orthoptera), mantids, moths (Lepidoptera), spiders (Araneae). Fruit of native and introduced species taken, including *Bakerella*, *Capparis*, *Canthium*, *Celtis*, *Chassalia*, *Clidemia*, *Cordia*, *Dianella*, *Ficus*, *Medinilla*, *Melia*, *Neotina*, *Oncostemum*, *Pauridiantha*, *Rinoria*, *Vaccinium*; flowers including *Crateva*. On Aldabra, fruit includes *Apodytes*, *Asparagus*, *Flacourtia*, *Mystroxylon*, *Passiflora*, *Phyllanthus*, *Polysphaeria*, *Scaevola*, *Scutia*, *Solanum*, *Terminali*, *Ticalysia*, *Ricinus*, and recorded as feeding at flowers of *Agave*, *Erythrina* and *Lantana*. Conspicuous and noisy. Gregarious when not breeding; often perches high in trees in groups of up to 15 individuals; active. Often joins mixed-species flocks. Communal roosts reported in Comoros (Mayotte), sometimes with Common Mynas (*Acridotheres tristis*). Usually forages in crowns of trees and bushes; rarely in understorey, except in areas of contact with *H. parvirostris* on Grand Comoro and Mohéli (Comoros), where tends to keep low in vegetation, with its larger congener in the higher strata. Also picks fruit by hovering or in awkward fluttering flight. Gleans insects from leaves and twigs, catches others in flight in sometimes long aerial sallies. Occasionally feeds on ground on Aldabra.
Breeding. Nesting recorded in Sept–Jan in Madagascar and Sept–Nov in Comoros; breeds mainly Oct–Jan on Aldabra. Nest hemispherical, firmly but not densely constructed of small twigs, fine rootlets, flower stems, dried grass, moss and plant fragments, lined with fine grass and plant stems, bottom may be loosely woven (eggs visible from below), parts of cast reptile skins reported as sometimes incorporated into foundation, external diameter 10–12 cm, depth 6·5–7 cm, internal diameter 7 cm, cup depth 3–5 cm; placed 1–8 m above ground, usually low, sometimes at end of branch, once secured to four points of two adjacent branches with spider webs, on Aldabra 1–2 m up in fork of thorny shrub. Clutch 3 eggs, records of 2 on Anjouan (Comoros); no information on incubation and fledging periods.



Movements. No information; presumed sedentary.
Status and Conservation. Not globally threatened. Common to very common. Common to abundant throughout much of Madagascar, where it has adapted well to deforestation; recorded mean densities of up to 2·7 birds/ha in Montagne d'Ambre, 117 birds/km² in Anjanaharibe-Sud, 270 birds/km² in Zahamena and 99–311/km² in Zombitse-Vohibasia. One of the three commonest bird species in the Comoros. Recently rediscovered on Grande Glorieuse, where had been reported as extinct; unclear whether earlier reports were incorrect or there has been a subsequent recolonization. Race *rostratus* widespread on Aldabra, where population estimated at 4000–8000 pairs; 19th-century records from nearby Cosmolédo and Astove may have referred to this race, but now extinct on those atolls. Present in a large number of protected areas on Madagascar; occurs in a number of reserves on Mayotte, but no protected areas exist in the Union of the Comoros. Aldabra Atoll is a nature reserve and World Heritage Site.

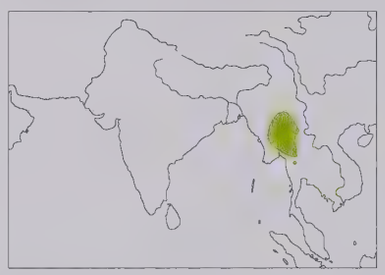
128. **Comoro Black Bulbul**

Hypsipetes parvirostris

French: Bulbul des Comores **Spanish**: Bulbul de Comores
German: Komoren-Rotschnabelbülbül
Other common names: Comoro Bulbul

Taxonomy. *Hypsipetes parvirostris* Milne-Edwards and Oustalet, 1885, Grand Comoro, Comoro Islands.
Sometimes considered to form a superspecies with all other members of genus, and in the past all have been treated as conspecific. Presence of two species of this genus in Comoros has long been contentious; significance of the olivaceous phenotypes restricted to Grand Comoro and Mohéli obscured by presence on all four main islands of *H. madagascariensis*. Shortly after its initial description, nominate race became treated as a hybrid between *H. madagascariensis* and *H. crassirostris*; subsequently, all Comoros forms considered sufficiently distinct in combination from Madagascar populations to merit subspecific rank, for which name *parvirostris* was used (despite the fact that the type was the supposedly "aberrant" olivaceous form); the larger olivaceous *moheliensis* was originally described as a race of *H. crassirostris*. It is now recognized that the olivaceous phenotype constitutes a separate species, which behaves as a parapatric vicariant of *H. madagascariensis* (replacing latter in montane forest habitats). Furthermore, recent molecular analysis suggests that *moheliensis* is not the sister-taxon of nominate and that it should be accorded rank of full species, a treatment supported by differences in size and vocalizations; retained as race of present species, pending fuller study of the two taxa. Two subspecies provisionally recognized.
Subspecies and Distribution.
H. p. parvirostris Milne-Edwards & Oustalet, 1885 – La Grille and Mt Karthala on Grand Comoro (Njazidja), in N Comoro Is.
H. p. moheliensis (Benson, 1960) – Mohéli (Mwali), in C Comoros.

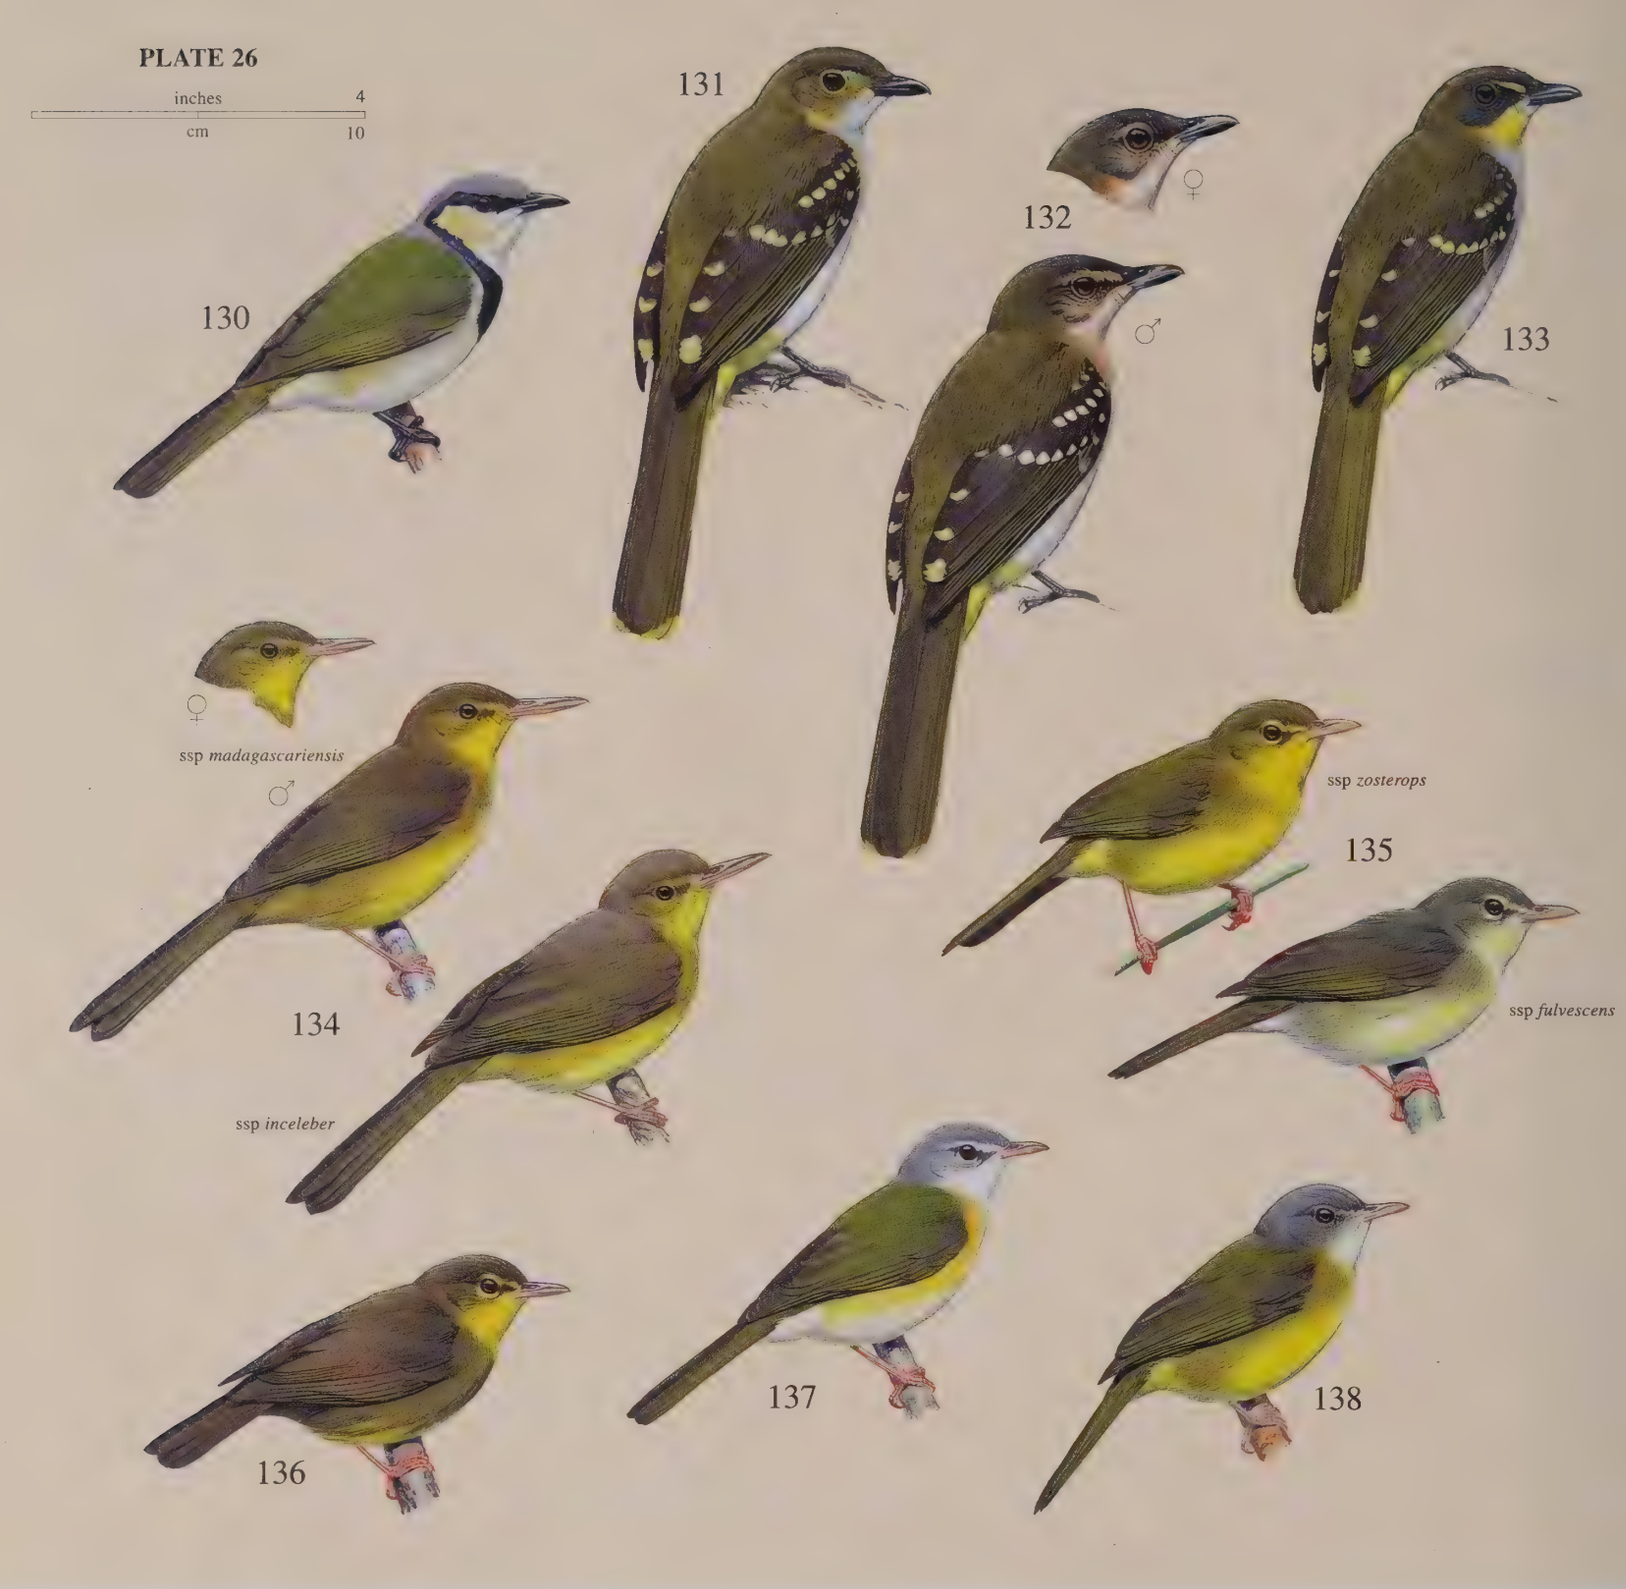
Descriptive notes. c. 25 cm; mean 56·9 g (nominate), 62·1 g (*moheliensis*). Large, olive bulbul, loose and pointed feathers of crown and nape often raised to form shaggy crest. Nominate race has top of head, nape and upper hindneck blackish, slightly glossy, with indistinct paler shaft streaking; lores blackish, mixed dark olive-green, cheeks, ear-coverts and side of hindcrown behind eye brownish olive-green; upperparts greenish-olive, feathers with variable amounts of brownish centrally, giving indistinctly mottled appearance; tail and wings olive-brown, flight-feathers and greater wing-coverts narrowly fringed greenish; throat, breast and flanks paler dirty yellowish olive-green, darkest on side of breast; belly pale dirty yellowish, undertail-coverts yellowish-white; iris chestnut-brown; bill dull orange; legs yellowish-brown or dull ochraceous brown. Differs from *H. madagascariensis* in larger size, proportionately shorter tarsi, and greenish or greenish-yellow (not grey) coloration, particularly ventrally. Sexes alike, female on average smaller than male. Juvenile is duller than adult, bill pale brown, with primaries, secondaries, alula and edges of wing-coverts and tail feathers rusty, some pale feathers on sides of head and neck. Race *moheliensis* is larger than nominate, with heavier bill, has belly dark like breast, vent and undertail-coverts with only a little yellow. Voice. Repertoire resembles those of congenerics in the region. Song of nominate an extended series of monotonous, loud nasal cacklings of limited variety, e.g. "swok-swuk-tchik-tchuk-waa-waa-tchuk-tchak-tchuk-tchik", with occasional short pauses between each series, speed and intensity of delivery varies, when more excited becomes higher-pitched "chewdly-cheoo-ch-ch–chewdly-chu-chewchu-chew-chu-chew"; main "cat call" a penetrating, nasal whine, "swaaaay" or "waaa". Vocalizations of race *moheliensis* similar in structure but slower, song somewhat lower-pitched and purer-toned, each element delivered in strident, measured, emphatic way, "tyo, tyu, tyo, tyu, tyo, tya, tyo, tyoo", somewhat reminiscent of *Nicator*, also may become more excited and faster "chack-chuck-chuck-chock-chuk"; call "thwaa thwaa", more strident and wheezing than that of *H. madagascariensis*.
Habitat. On Grand Comoro confined to natural forests, including clearings and associated degraded areas, on peaks of La Grille and Mt Karthala at 500–1850 m (limits of forest), but less frequent above 1000 m; associated with mature forest, pioneer forest on lava flows, forest underplanted with banana and taro, less frequent in logged forest in which structure has been destroyed. On Mohéli (*moheliensis*) in forests of central ridge, mainly above 200–400 m, to 790 m. On both islands replaces *H. madagascariensis* at higher altitudes, the two overlapping at 500–750 m on Mt Karthala, extensively at same altitudes on La Grille, and at 200–500 m on Mohéli.
Food and Feeding. Little information. Berries and other fruit, including exotic *Rubus rosifolius*, and insects. Gregarious, in noisy groups. Nominate race forages mainly in upper strata and crowns of trees; *moheliensis* much more in understorey.
Breeding. Fledglings seen in Nov on Grand Comoro. Nest (of nominate) a thick, firm cup of mosses, ferns, dead leaves and stems, larger than that of *H. madagascariensis*, built in fork of bush. No other information.
Movements. No information; likely sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Comoro Islands EBA. Both races considered to be common or very common within remaining limited forest habitat; until recently, status was obscured by taxonomic confusion and identification problems. Forests on both islands lack any formal protection, and are threatened with clearance for agriculture. Continuing forest loss would potentially threaten this species, as it seems unable to adapt well to heavily modified habitat, or is outcompeted, at least at lower altitudes, by *H. madagascariensis*.
Bibliography. Benson (1960), Cheke & Diamond (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Herremans (1988, 2001), Louette (1988, 2004, 2005), Louette & Herremans (1985), Louette & Stevens (1992), Louette, Bijnens *et al.* (1989), Louette, Stevens *et al.* (1988), Milne-Edwards & Oustalet (1888), Safford & Evans (1992), Sinclair & Langrand (1998), Stattersfield *et al.* (1998), Stevens *et al.* (1995), Warren (2003).



Genus *CERASOPHILA* Bingham, 1900

129. **White-headed Bulbul**

Cerasophila thompsoni



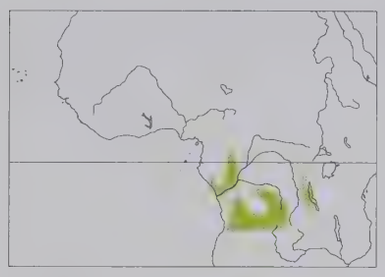
French: Bulbul à tête blanche **German**: Thompsonbülbül **Spanish**: Bulbul Cabeciblanco
Other common names: Bingham's (White-headed)/Brown-vented Bulbul

Taxonomy. *Cerasophila Thompsoni* Bingham, 1900, Southern Shan States, Myanmar.
Often included in an expanded genus *Hypsipetes*. Monotypic.
Distribution. N, C, E & S Myanmar (Bhamo district S to N Tenasserim) and W & NW Thailand.

Descriptive notes. 20 cm; 42 g. Distinctive, medium-sized bulbul. Entire head, upper neck and throat are pure white, apart from thin black loral streak extending around upper side of eye as partial black eyering; upperparts uniform pale smoky grey; wings and tail mid-grey, fringed paler ashy grey; upper breast to lower belly pale smoky grey (as upperparts), vent and undertail-coverts conspicuously rufous-chestnut; iris light yellow or brownish-yellow, edge of eyelid bright vermilion or orange-red (narrow patch of darker bare skin around eyering); bill coral-red, tip paler yellow or horn; legs coral-red, claws horny brown or brown with orange tinge. Distinguished from similar white-headed races of *Hypsipetes leucocephalus* by smaller body and bill, lack of shaggy crown and throat feathers, paler plumage, richly coloured undertail-coverts. Sexes alike. Juvenile is browner overall, with olive-buff edgings of grey feathers, head initially brownish-grey, darkest on crown side, gradually turning white. Voice. Singles or pairs generally silent unless singing, but flocks can be noisy. Song of variable short squeaky phrases, including rhythmic "chit-chirui chit-chiriu"; calls generally harsher and more buzzing than equivalent notes of *H. leucocephalus*.
Habitat. Forest edges, secondary forest, lightly wooded country, poppy gardens, park-like areas of scrub or grass with widely spaced pines (*Pinus*) or other trees. Usually at 900–2135 m; straggles to lower altitudes in non-breeding season, once down to 150 m.
Food and Feeding. Diet little known; one stomach from N Thailand contained only insects. Forages in loose flocks of up to 20 individuals; restless arboreal habits, as *H. leucocephalus*. Often perches openly on dead trees, and flies at considerable heights over open areas.
Breeding. Mar–Jul in N Thailand. Nest (in Myanmar) a fairly shallow cup built of grass seed-stems (possibly of *Saccharum arundinaceum*), grass and bamboo leaves, and hidden 1–2 m up in low bank, sometimes in pronounced recess; one was made of coarse grass, lined with fine grass, attached to stems of a plant just above ground on steep cleared slope. Clutch 2–4 eggs; no information on incubation and fledging periods.
Movements. Generally resident. Some evidence of post-breeding downslope movement; arrives in numbers in winter months in N Thailand.
Status and Conservation. Not globally threatened. Locally fairly common in its relatively small range; e.g. common in Karen Hills, in Myanmar. Quite common in N Thailand during winter months, at which time protected areas such as Doi Inthanon National Park support important populations.
Bibliography. Bingham (1903), Deignan (1945), Dickinson *et al.* (2002b), Gregory (2000), Lekagul & Round (1991), Mackenzie (1929), Prater (1923), Riley (1938), Rippon (1901), Robson (2000), Round (1988), Smythies (1986), Wickham (1924, 1929–1930).

PLATE 26 ➤

Genus *NEOLESTES* Cabanis, 1875



130. Black-collared Bulbul

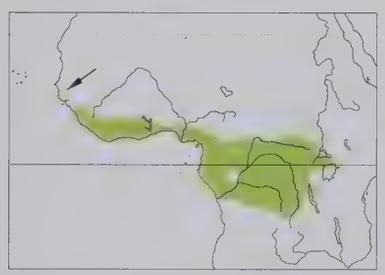
Neolestes torquatus

French: Bulbul à collier noir **German**: Rüttelbülbül **Spanish**: Bulbul Acollarado

Taxonomy. *Neolestes torquatus* Cabanis, 1875, Chinchoxo, Angola.
Has often been placed with the bush-shrikes (Malaconotidae) or the helmet-shrikes (Prionopidae) because of obvious similarities in plumage colour and pattern, or considered of uncertain position. Recent skeletal and molecular studies indicate that this species is best placed within present family; phylogenetic analysis suggests that it is basal to other bulbuls within a monophyletic clade. Monotypic.

Distribution. Extreme S & SE Gabon and C & S PRCongo S to NW & N Angola (Cabinda, and S to Huambo and Moxico), SC & E DRCongo (including, in E, Idjwi I and from near Mt Kabobo S to Marungu Highlands) and extreme NW Zambia.
Descriptive notes. c. 16 cm; male 20–23·5 g, female 20–27 g. A handsome, unmistakable, shrike-like bulbul. Has forehead to neck grey, broad glossy black band from lores and around eye onto ear-coverts, then extending down side of neck and broadening across upper breast to form gorget; upperparts olive-green, tail feathers dark brown, edged olive-green, wings bright olive-green, edges of flight-feathers more yellowish-green, bend of wing yellow; chin, throat and cheeks creamy white, ear-coverts buffy, lower breast buffy white, breast side and flanks washed greyish, lower flanks tinged olive-green; iris dark brown; bill greenish-black or dark olive-green; legs black. Sexes alike, no sexual dimorphism in size. Juvenile is duller, top of head greenish, some mantle feathers with pale edges, olive-brown scapulars and upperwing-coverts tipped buff (forming pale barring across greater and median coverts), breastband dull. Voice. Song a rapid subdued babble, somewhat resembling that of *Pycnonotus barbatus* but phrases more mellow and fluid. Call notes "twee-dududu", "tji-li-li" and "dee-de-de-de-de", and softer nasal trill; twittering notes when foraging.

Habitat. Wooded grassland with 20–30% bush cover (mainly *Annona senegalensis* and *Hymenocardia acida*); prefers dense grassland 1–2 m tall, often of *Hyparrhenia*. Also secondary miombo woodland scrub, overgrown cultivation, termitarium thicket and *Lantana* thicket. Sea-level to 1750 m; rarely, to 2060 m in E DRCongo (Marungu).
Food and Feeding. Mainly insectivorous but also some fruit. Occurs singly, in pairs, or in groups of up to four individuals (thought to be family parties). Perches boldly on bare branches or fence posts. Hawks insects in the air; also drops into grass to take them. Active and restless, quickly working through an area.
Breeding. Nesting recorded in Aug–Oct and Dec–Jan (juveniles Dec–Feb) in DRCongo and Oct and Jan in Zambia; birds in breeding condition in Jul and Oct–Dec and fledgling in Mar in Angola. Solitary breeder, territorial, territories well spaced. As possible breeding display, a bird darted up into air in short jerky flight with noisy wingbeats for c. 30 m, remained there for several minutes before descending rapidly and jerkily, performance accompanied by continuous chattering. Nest a frail, untidy, unlined transparent cup made of thin layers of fine, dry grass, with or without a few plant stems, and with many gaps, external diameter 7·5–8·5 cm, internal diameter 5·5–6·5 cm, cup depth 4 cm, placed c. 1 m above ground in fork of 1·5 m-tall bush in open area of grass and scattered bushes outside miombo scrub; another was built in *Combretum* bush. Clutch 2 eggs; no information on incubation period; chicks fed by both parents, visiting nest together at intervals of up to 30 minutes; young leave nest by day 17, attended by parents in adjacent bush.
Movements. Little information; probably resident.
Status and Conservation. Not globally threatened. Generally considered common. Estimated density in Odzala National Park, in PRCongo, 4–5 pairs/km². Occurs in a number of protected areas, including Odzala National Park, Conkouati Reserve and Lefini Faunal Reserve, in PRCongo, and Lekoni National Park, in Gabon.
Bibliography. Bannerman (1939), Benson *et al.* (1971), Borrow & Demey (2001), Bowen (1983), Chapin (1921, 1953), Chappuis (1975), van Daele (1999), Dean (2000), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett & Prigogine (1974), Dowsett, Aspinwall & Dowsett-Lemaire (2004), Dowsett, Olson *et al.* (1999), Dowsett-Lemaire & Dowsett (1991), Fry *et al.* (2000), Hall & Moreau (1970), Lippens & Wille (1976), Mackworth-Praed & Grant (1960, 1963, 1973), Rand *et al.* (1959), Salvan (1972).



Genus *NICATOR* Hartlaub & Finsch, 1870

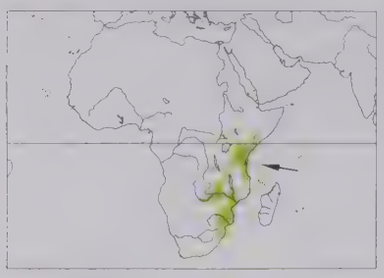
131. **Western Nicator**

Nicator chloris

French: Bulbul nicator **German**: Graukehlnicator **Spanish**: Conquistador Occidental
Other common names: Yellow-spotted/Common Nicator

Taxonomy. *Lanius chloris* Valenciennes, 1826, Galam, Senegal.
Systematic position of genus long a subject of debate. Traditionally classified within a broad family Laniidae on basis of similarities in coloration and bill morphology, and has at different times been placed with the Malaconotidae (formerly part of Laniidae) and with present family, depending on varying interpretations of the significance of different morphological characters. Analyses of feather proteins and early studies of DNA–DNA hybridization both favoured placement in present family, but genus appears unique in a number of morphological and other features (including nest structure). Recent DNA studies suggest that it is not closely related to any other group, and that it appears to represent a separate, monogeneric family. For convenience, retained within present family pending further investigation. Present species forms a superspecies with *N. gularis*, and often considered conspecific. Monotypic.
Distribution. Senegambia and S Guinea E to extreme S Sudan (Imatong Mts) and E Uganda, S to N Angola and S DRCongo, also extreme NW & W Tanzania.

Descriptive notes. 20–23 cm; male 48–67 g, female 32–51 g. Distinctive, shrike-like bulbul with relatively heavy hooked bill, conspicuous yellow spotting on wings, feathering of lores and preorbital area stiff, short and upward-pointing. Plumage is dark olive-green above, rump and uppertail-coverts more yellowish-green; tail dark green, edges tinged yellowish, tips of all except central pair also yellowish, widening from c. 1 mm on second pair (T2) to c. 10 mm on outer edge of outermost (T6); stiff feathers closest to bill and extending onto crown side black, forming dorsal edge of supraloral streak, those beneath and nearer eye pure white (a few with black tips); row of black preorbital bristles around leading edge of eye, extending in arc from beneath supraloral streak to above rear of gape; wings dark brown, outer primaries with narrow bright yellow edges, outer edges of inner primaries, secondaries and tertials olive-green, inner secondaries and tertials with large yellow terminal spot on outer web, remaining secondaries with narrow yellow tips; primary coverts with greenish outer edge and yellow tip, secondary coverts with large yellow terminal spot (three rows of contrasting yellow spots across upperwing-coverts); throat grey, yellow at side, breast grey, greener on side, flanks greyish-white, centre of belly off-white, thighs greenish-yellow, undertail-coverts bright yellow, underwing-coverts and axillaries yellow; iris brown, grey-brown or chestnut-brown, orbital ring and gape dull yellow; bill black; legs blue-grey. Differs from very similar *N. gularis* in more olive-green (less grey) crown. Sexes similar, female on average much smaller than male. Juvenile is slightly paler above, lower breast and belly pure white. Voice. Song powerful, melodious and very varied, comprising explosive crescendo of clear whistles, guttural rattles, etc., likened by some to that of Common Nightingale (*Luscinia megarhynchos*), typically begins with churring notes and ends with pure ones, "tuk-tutuk-turrr-wick", "tuk-tichur-ti-weety-weety-wok", "wee-tip-chup chorra chorra chorra"; sometimes launches straight into whistles, e.g. "weeoo chopa" or "wop-wop-cheep-cheep woja"; sometimes no pure whistles, as "chup-chup-chup-chup" ending with shrike-like, descending "teeurrrrr". Will mimic other species, including Sjöstedt's Owlet (*Glaucidium sjostedti*), African Pied Hornbill (*Tockus fasciatus*) and Yellow-bellied Wattle-eye (*Diaphorophyia concreta*), as well as *N. vireo*. Common call a loud "chuk" or "chok", also longer, more subdued series of dry "tuk" notes at irregular intervals, and loud, insistent "gwa-gwa-gwa-gwa"; contact call a series of clicks.
Habitat. Primary and secondary evergreen and semi-deciduous forest, swamp-forest, gallery forest, and areas of dense shrubbery in savanna zone; in secondary situations such as logged forest and shaded cacao plantations, along logging roads and beside watercourses. Infrequent or absent in closed-canopy forest with open understorey. Mainly lowlands, but also in forests up to 1400–1500 m, exceptionally to 1800 m.
Food and Feeding. Arthropods, including large orthopterans, mantids, beetles (Coleoptera), caterpillars; also vertebrates such as small frogs; a few berries and seeds. Occurs in pairs, but partners often forage some distance apart; sometimes joins mixed-species flocks. Works slowly and methodically through dense undergrowth and more open vegetation; inquisitive but skulking. Explores tangled lianes, bunches of dead leaves, epiphytic vegetation on trunks and branches, thick regrowth in treefall gaps and similar places, mainly in understorey and middle strata at 5–25 m; occasionally down to ground level. Spread rectrices laterally when foraging; flicks wings and pumps tail when excited.
Breeding. Nesting recorded in Apr in Sierra Leone, Feb and Nov (immatures Feb, Apr, Jul–Aug) in Liberia and Dec in Ivory Coast; Jun (breeding condition Mar, May, also dependent young Oct) in Nigeria, Apr–Jun and Aug in Cameroon; all year, peak during rains and short dry season, in Gabon, and May–Nov (breeding condition Feb, Apr, Dec) in DRCongo; Jul–Aug in Sudan and Apr and Jun–Jul in Uganda; birds in breeding condition in Jun in Central African Republic and Feb–Mar in Angola. Monogamous. Territorial; in aggressive situations, holds wings out from body and spreads tail while singing. Courting male seen to crouch silently on branch, spread wings and tail, hop several times and squat again. Nest small and rudimentary, 6 × 6 cm, built from a few sticks which support tendrils and rotting twigs, selected twigs in state of decomposition in order that fungus growing on them spreads across whole nest, so binding it together and to support, resulting structure appearing extremely fragile (many nests destroyed before mycelial growth sufficient to hold them together); placed 0·4–4·5 m above ground among leaves in undergrowth, sometimes in fork or on bundle of dead leaves hanging from branch; territory size 3–4 ha in PRCongo. Clutch 1 egg (nest too small to accommodate more); incubation by female only, period 17–18 days; chick fed by both parents (with relatively large prey) on average once every 30 minutes, leaves nest by 16–18 days, well before able to fly, moves into neighbouring branches; watched over by one parent, remains motionless, well camouflaged by its spotted appearance, when parent gives alarm call. Of 30 nests in Gabon, 17 produced flying young; four nests lost when blown down before fungal growth had secured structure.
Movements. Sedentary, at least in Gabon.
Status and Conservation. Not globally threatened. Generally common throughout its range. Present in numerous national parks, including those of Sapo, in Liberia, Taï Forest, in Ivory Coast, Kakum, in Ghana, Cross River, in Nigeria, Korup, in Cameroon, Lopé, in Gabon, Nouabalé-Ndoki, in PRCongo, Salonga, in DRCongo, Kibale Forest, in Uganda, and Mahali Mountain, in Tanzania.
Bibliography. Bannerman (1939), Barlow *et al.* (1997), Borrow & Demey (2001), Britton (1972, 1980), Brosset (1971a), Brosset & Érard (1976, 1986), Brown & Britton (1980), Carswell (1986), Chapin (1921, 1953), Cheke & Walsh (1996), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dean (2000), Demey & Fishpool (1994), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1991), Elgood *et al.* (1994), Fishpool & Evans (2001), Fishpool *et al.* (1994b), Fry *et al.* (2000), Gatter (1997), Gore (1990), Grimes (1987), Hall & Moreau (1970), Jackson & Sclater (1938), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1960, 1963, 1973), Morel & Morel (1990), Nikolaus (1987, 1989), Prigogine (1971, 1978, 1984), Sargeant (1993), Schouteden (1957), Stevenson & Fanshawe (2002), Thiollay (1985).



132. **White-throated Nicator**

Nicator gularis

French: Bulbul à tête brune **German**: Braunkopfnicator **Spanish**: Conquistador Oriental
Other common names: Eastern/Zambesi Nicator

Taxonomy. *Nicator gularis* Hartlaub and Finsch, 1870, Shupanga, Zambesi.
Systematic position of genus long a subject of debate. Traditionally classified within a broad family Laniidae on basis of similarities in coloration and bill morphology, and has at different times been placed with the Malaconotidae (formerly part of Laniidae) and with present family, depending on varying interpretations of the significance of different morphological characters. Analyses of feather proteins and early studies of DNA–DNA hybridization both favoured placement in present family, but genus appears unique in a number of morphological and other features (including nest structure). Recent DNA studies suggest that it is not closely related to any other group, and that it appears to represent a separate, monogeneric family. For convenience, retained within present family pending further investigation. Present species forms a superspecies with *N. chloris*, and often considered conspecific. Populations of Zambesi Valley (from Zambia E to C Mozambique) described as race *phyllophilus* on basis of paler browner forecrown, more greyish-yellow hindcrown and neck and brighter upperside, but differences from populations in rest of range slight, and considered insufficient to warrant naming of geographical races. Monotypic.
Distribution. S Somalia, SE Kenya, NE & E Tanzania (including Zanzibar, also scattered records farther W), S Zambia, parts of N, E & SE Zimbabwe, and much of Malawi and S Mozambique S to NE South Africa (KwaZulu-Natal) and E Swaziland; disjunct population in extreme SE DRCongo and adjacent NW Zambia.
Descriptive notes. 20–23 cm; male 40–63 g, female 29–41 g. Distinctive, shrike-like bulbul with relatively heavy hooked bill, conspicuous pale yellow spots on wings, feathering of lores and preorbital area stiff, short and upward-pointing. Top of head is olive-grey, upperparts dull olive-green; tail feathers greenish-brown, edged yellowish, tips of all except central pair also pale yellowish, widening from c. 1 mm on second pair (T2) to c. 7 mm on outer edge of outermost (T6); stiff feathers closest to bill and extending onto side of crown as the dorsal edge of supraloral streak

On following pages: 133. Yellow-throated Nicator (*Nicator vireo*); 134. Common Tetraka (*Bernieria madagascariensis*); 135. Short-billed Tetraka (*Xanthomixis zosterops*); 136. Dusky Tetraka (*Xanthomixis tenebrosus*); 137. Appert's Tetraka (*Xanthomixis apperti*); 138. Grey-crowned Tetraka (*Xanthomixis cinereiceps*).

are blackish, those beneath and nearer eye pale yellow; row of black preorbital bristles around leading edge of eye, extending in arc from beneath supraloral streak to above rear of gape; narrow pale yellow orbital ring; sparse feathering behind and below eye pale buffish-brown, becoming more olive-green on rear of ear-coverts; wings dark brown, outer primaries with narrow whitish edges, outer edges of inner primaries, secondaries and tertials greenish, inner secondaries and tertials with large pale yellow terminal spot on outer web, remaining secondaries with narrow yellow tip; primary coverts with narrow yellowish tip, greater and median secondary coverts with large yellowish white terminal spot (three rows of contrasting pale yellow spots across upperwing-coverts); throat buffish-white, upper breast greyish-brown, greener at side and becoming greyish-white on flanks and whitish on centre of belly; thighs pale greenish-yellow, undertail-coverts pale yellow; underwing-coverts and axillaries yellow; iris brown or yellowish-brown; bill horn, greyish-brown, blackish or pale grey, paler cutting edges; legs slate or pale blue-grey. Sexes similar, female on average much smaller. Juvenile has primaries yellow-tipped. Voice. Song, from high well-concealed perch, less frequently from exposed one, starts with a few low notes, "tik-chopweeoo-tok", followed by emphatic "trrr" and then loud, liquid whistling, e.g. "hip-to-wee-to-chip to-weet", "weeo wee, wee-ee-oo-chowee", "chip-chop-chipweooo-trrr… chip-to-weet" or "chwik, cheeerk, chwick, wherrreek, cho-chidilee", resembles that of *N. chloris*; duration c. 3 seconds, interval between songs may be filled with low conversational notes. Recorded as mimicking other species, including Moustached Green Tinkerbird (*Pogoniulus leucomystax*) and Eastern Black-headed Oriole (*Oriolus larvatus*). Alarm call a penetrating "tsuck" or "zokk"; also softer "tsuk-tsuk" and whistled "wee-oo".

Habitat. Coastal forest and lowland rainforest, riparian forest, evergreen and deciduous thickets, transition woodland, moist thornveld and coastal scrub; locally in second growth and suburban gardens. Mainly lowlands, occasionally reaching 1400 m in Malawi, 1550 m in Zambia, 1900 m in Kenya and 2150 m in Tanzania.

Food and Feeding. Arthropods, including large orthopterans, beetles (Coleoptera) and caterpillars. Occurs singly or in pairs; occasionally joins mixed-species flocks (reputedly females only; basis for this unclear). Secretive and inconspicuous when not calling, usually skulking in dense cover. Forages from ground level to canopy, usually in understorey, hopping unhurriedly from branch to branch, while looking about for prey; also actively searches in clumps of dried leaves. Also descends to ground level to work leaf litter, from where it takes prey up to a low branch to consume it. May flick wings while foraging, holding them half open and drooped. Seen also to fly silently and repeatedly in tight horizontal and oblique circuits close around base (at 0–2 m) of multi-stemmed low tree, while fanning tail and flirting wings (yellow spotting very conspicuous); this interpreted as behaviour intended to startle cryptic trunk-dwelling or hidden prey into movement, although none seen to be taken. Also follows small and large ungulates, feeding on insects flushed by their movement; occasionally perches on them to glean ticks, etc.

Breeding. Nesting recorded in Jun and Nov–Dec in Kenya and Tanzania, and birds in breeding condition Oct–May (from beginning of short rains until end of long rains) in coastal Tanzania; in Jan in Zambia, Dec–Jan in Malawi, Nov–Dec (also breeding condition Mar) in Mozambique, Jan in Zimbabwe, and Nov–Jan in South Africa. Monogamous. Solitary nester; territorial. Nest flat, rudimentary, a triangle of stout twigs supporting smaller twigs and tendrils, sometimes with rootlets, bamboo leaves, moss or stems and leaves of *Lantana* incorporated, the whole appearing too insubstantial to support the bird, external diameter 10–15 cm (outer edges very diffuse), cup diameter 7·5 cm; placed usually low down, c. 1 m above ground, in small bush of forest undergrowth, in tangle of dead branches, among stems of mat of creepers, or in forked branch of sapling, well concealed or sometimes exposed, once in full view 1·5 m from path in mass of thorns above large rock. Clutch 1–4 eggs, usually 2–3; incubation by female only; no information on incubation and nestling periods.

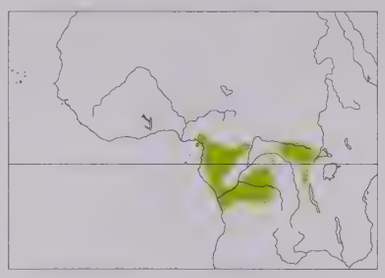
Movements. Thought to be sedentary.

Status and Conservation. Not globally threatened. Uncommon and locally common to common in different parts of range. Population in S Mozambique estimated to be at least 10,000 birds. Estimated densities in Swaziland 2·7 birds/100 ha in broadleaf woodland and 20 birds/100 ha in riverine forest; in most favoured habitats in Malawi, reaches 3–5 pairs/10 ha. Well represented in numerous protected areas, including Kruger National Park, in South Africa.

Bibliography. Ash & Miskell (1983, 1998), Benson & Benson (1977), Benson *et al.* (1971), Britton (1972, 1980), Brown & Britton (1980), Clancey (1964, 1996), Cordeiro (1994a), Dowsett & Dowsett-Lemaire (1980, 1993), Dowsett & Forbes-Watson (1993), Dowsett *et al.* (2004), Dowsett-Lemaire (1989), Dowsett-Lemaire & Dowsett (2004), Fry *et al.* (2000), Ginn *et al.* (1989), Hall & Moreau (1970), Hanmer (1978), Harrison *et al.* (1997), Irwin (1981), Jackson & Sclater (1938), Lewis & Pomeroy (1989), Lippens & Wille (1976), Long (1959), Mackworth-Praed & Grant (1960, 1963), Maclean (1993), Mlingwa (1996a), Monadjem (2002b, 2003), Moreau & Moreau (1937, 1939), Pakenham (1979), Parker (1999), Roche & Kilpin (2003), Stevenson & Fanshawe (2002), Tarboton (2001), Turner & Zimmerman (1979), Vernon & Dean (2005b), Zimmerman *et al.* (1996).

133. **Yellow-throated Nicator**

Nicator vireo



French: Bulbul à gorge jaune **German**: Gelbkehlnicator **Spanish**: Conquistador Gorgiamarillo

Taxonomy. *Nicator Vireo* Cabanis, 1876, Chinchoxo, Angola.

Systematic position of genus long a subject of debate. Traditionally classified within a broad family Laniidae on basis of similarities in coloration and bill morphology, and has at different times been placed with the Malaconotidae (formerly part of Laniidae) and with present family, depending on varying interpretations of the significance of different morphological characters. Analyses of feather proteins and early studies of DNA–DNA hybridization both favoured placement in present family, but genus appears unique in a number of morphological and other features (including nest structure). Recent DNA studies suggest that it is not closely related to any other group, and that it appears to represent a separate, monogeneric family. For convenience, retained within present family pending further investigation. Monotypic.

Distribution. W & S Cameroon, SW Central African Republic and N & W PRCongo S to N Angola, also W, SW, NE & E DRCongo and extreme W Uganda.

Descriptive notes. c. 16–18 cm; male 21–26 g, one female 23·5 g. Small, shrike-like bulbul with relatively heavy hooked bill, conspicuous yellow spots on wings, feathering of lores and preorbital area stiff, short and upward-pointing. Forehead and crown are greyish-olive, hindcrown and upperparts olive-green; tail paler and yellower green, tips of all except inner two feather pairs bold

yellowish, yellow widening from c. 1 mm on third pair (T3) to c. 6 mm on outer edge of outermost (T6); stiff feathers forming well-defined two-tone contrasting supraloral streak extending from base of bill to above eye, narrowly black above, wider bright yellow below; row of black preorbital bristles around leading edge of eye, extending in arc from beneath supraloral streak to above rear of gape; periorbital area, cheek and ear-coverts olive-grey; flight-feathers dark brown, narrowly fringed bright olive-green, inner secondaries and tertials with large yellow terminal spot; larger upperwing-coverts dark brown, primary coverts narrowly fringed yellow, greater and median coverts with large pale yellow terminal spot, lesser coverts dark green (two rows of contrasting yellow spots across upperwing-coverts); chin grey, throat and side of neck yellow or yellowish-green; breast and flanks grey, washed greenish laterally, belly greyish-white, thighs green, undertail-coverts yellow or greenish-yellow; underwing-coverts and axillaries yellow; iris brown or grey-brown; bill blackish or blackish-horn above, blue-grey or pale grey below; legs grey of blue-grey. Differs from *N. chloris* in smaller size, yellow throat, more extensive, yellow supraloral streak. Sexes alike, female on average smaller than male. Juvenile has forehead green, less yellow on throat. Voice. Song, from dense cover, a loud, far-carrying series of 8–11 resonant, explosive notes, "ko-kwee-ko-ko-ko-kwee-kuk-kuk" or "po-tyoo-ho-ho-ho-whee, tyoo-ho-ho", with some variations. Calls include angry "gwrrrrrr".

Habitat. Primary forest and old secondary forest, also abandoned cultivation and beside logging roads once regrowth sufficiently dense; also forest remnants in coffee plantations. Lowlands; reaches 870 m in DRCongo and 900 m in Uganda.

Food and Feeding. Arthropods, including orthopterans, mantids, beetles (Coleoptera) and caterpillars. Usually solitary, in territorial pairs. Extremely shy and skulking; forages usually 2–8 m above ground level, favouring dense understorey and disturbed areas such as treefall gaps, margins of clearings and ecotone between unlogged and regenerating forest. Likes damp spots and riverine vegetation.

Breeding. Nesting recorded in Oct in Cameroon and Dec–Mar (but extended season suspected) in Gabon; birds in breeding condition in Feb and Jul and juveniles in Mar and Jul in Angola. Territorial; same area occupied for many consecutive years. One nest described, a tangled mass of thin, dry creeper tendrils with shallow cup in centre, built upon base of dead twigs in form of a rectangle, external diameter 15 cm, internal 7 cm, placed 0·75 m above ground on small branches and skeletonized leaves of bush in thick undergrowth at forest edge, 12 m from cleared area. Clutch 2 eggs; incubation by female only, male sings nearby; no information on incubation and nestling periods; young out of nest fed by both parents.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Not uncommon to common. Estimated densities in Gabon 1 pair/20 ha in primary forest and 2–3 pairs/10 ha at forest edge. Occurs in a number of national parks, including those of Campo Ma'an, in Cameroon, Gamba, in Gabon, Dzanga-Ndoki, in Central African Republic, Odzala, in PRCongo, Salonga, in DRCongo, Quiçama, in Angola, and Semliki, in Uganda.

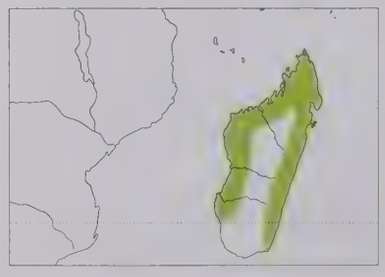
Bibliography. Bannerman (1939), Borrow & Demey (2001), Britton (1972, 1980), Brosset (1971a), Brosset & Érard (1976, 1986), Chapin (1953), Christy & Clarke (1994), Dean (2000), Dean *et al.* (2002), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1991), Fishpool & Evans (2001), Fry *et al.* (2000), Green & Rodewald (1996), Hall & Moreau (1970), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1960, 1963, 1973), Prigogine (1971, 1978, 1984), Sargeant (1993), Schouteden (1957), Stevenson & Fanshawe (2002).

Genus *BERNIERIA* Bonaparte, 1854

134. **Common Tetraka**

Bernieria madagascariensis

French: Bulbul tétraka **German**: Gmelinbülbül **Spanish**: Bulbul Tetraka
Other common names: Long-billed/Madagascar Greenbul



Taxonomy. *Muscicapa madagascariensis* J. F. Gmelin, 1789, Madagascar.

Relationships with rest of family uncertain. Previously thought close to species currently placed in *Xanthomixis* but formerly included in present genus; recent data derived from mitochondrial DNA sequencing indicate, however, that the two groups are not monophyletic. Two subspecies recognized.

Subspecies and Distribution.

B. m. inceleber Bangs & Peters, 1926 – N & W Madagascar (Montagne d'Ambre and Sambirano S to Toliara), including Nosy Be.

B. m. madagascariensis (J. F. Gmelin, 1789) – E Madagascar (Andapa S to Tolagnaro), including Sainte Marie I.

Descriptive notes. 17·5–20 cm; male 22–39 g, female 20·5–31·5 g. A medium-sized, slender species, notable for distinctive long and thin bill, upper mandible with terminal hook, lower mandible slightly inflated centrally, and marked sexual dimorphism in size. Has top of head and upperparts, including tail, dull dark brownish-green, wings slightly darker, flight-feathers brown with indistinct narrow yellowish edges; lores, cheeks and ear-coverts dull brownish-green, ill-defined darker eyestripe, indistinct, narrow paler olive-yellow supercilium, most obvious in front of eye, ear-coverts brownish-green thinly streaked with olive-yellow; inconspicuous narrow eyering yellowish-green above and below eye, darker brownish-green before and behind eye (thus blending with supercilium and eyestripe);

chin and throat yellow, centre of breast and upper belly duller yellow to off-white, rest of breast, flanks, lower belly and undertail-coverts olive-green; iris chestnut or mid-brown; upper mandible dark grey-brown, lower mandible dark brown distally, pinkish-horn basally and on underside, cutting edges of both mandibles pale; legs brown or greyish-brown. Differs from *Xanthomixis zosterops* in longer bill, lack of contrasting eyering, duller coloration above and below. Sexes similar, except that female on average much smaller and with proportionately shorter bill. Juvenile is duller and browner above, supercilium and eyestripe less developed, underparts less yellow, bill shorter and paler. Race *inceleber* has upperparts paler and greyer than nominate. VOICE. Song, at all hours of day, usually from concealed perch at c. 10 m, an irregular series of melodious notes, "chee tee tee tee", loud initially but becoming quieter, often preceded by few well-separated "tchip" notes, song repeated after a few seconds. Contact call a short, repeated characteristic "chep" or "cherr" and short rattle; alarm also a rattled "chack"; calls deeper and harsher than those of *Xanthomixis*.

Habitat. Primary evergreen forest in E, and dry deciduous forest in W; infrequently, adjacent secondary areas. From sea-level to 1300 m in E, to 1000 m in W.

Food and Feeding. Arthropods, including beetles (Coleoptera), cockroaches (Blattodea), ants (Hymenoptera), bugs (Hemiptera), orthopterans, lepidopterans, spiders (Araneae), millipedes (Diplopoda); also small vertebrates (geckos). Gregarious; occurs in groups of 3–10 individuals, often with *Xanthomixis zosterops*, and a regular component of mixed-species flocks. Noisy and bold. Prefers lower and middle strata, 1–20 m, but less frequently in undergrowth than *X. zosterops*. Forages in dense vegetation, carefully inspecting bunches of dead leaves, fallen trees, bases of palm fronds, epiphytes. Often climbs up and down trunks and branches, including vertical ones, looking for prey. Feeds by gleaning and probing.

Breeding. Birds in breeding condition in Nov, dependent young in Dec and immatures in Sept, Nov–Jan and Mar; thought to breed Sept–Feb; song is most evident Dec–Feb. No other information.

Movements. No information; presumed sedentary.

Status and Conservation. Not globally threatened. Generally common, although rather less so in SW of range. Mean recorded densities of 1·7–2·3 birds/ha in Montagne d'Ambre, 157–214/km² in Andohahela, 68 birds/km² in Anjanaharibe-Sud, 53 birds/km² in Zahamena. Found at most forest sites and occurs in numerous protected areas, including Montagne d'Ambre, Masaola, Ankarafantsika, Mantadia-Analamazaoatra, Ranomafana, Kirindy, Zombitse-Vohibasia and Andohahela.

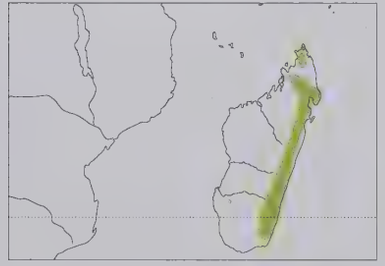
Bibliography. Benson & Irwin (1975), Benson *et al.* (1976), Cibois *et al.* (2001), Dee (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fjeldså *et al.* (1999), Goodman (1993), Goodman & Benstead (2003), Goodman & Parillo (1997), Goodman & Puttnam (1997), Goodman, Andrianarimisa *et al.* (1996), Goodman, Hawkins & Razafimahaimodison (2000), Goodman, Pidgeon *et al.* (1997), Hawkins (1995, 1999), Hawkins & Goodman (1999), Hawkins *et al.* (1998), Hino (1998), Langrand (1990, 1995), Milon *et al.* (1973), Morris & Hawkins (1998), Mustoe, Capper, Lowen, Leadley & Rakotomalala (1998), Mustoe, Capper, Lowen, Leadley, Rakotomalala & Randrianarivo (2000), Rand (1936), Safford & Duckworth (1990), Sinclair & Langrand (1998), Thompson & Evans (1991), Thompson *et al.* (1987).

Genus *XANTHOMIXIS* Sharpe, 1881

135. **Short-billed Tetraka**

Xanthomixis zosterops

French: Bulbul à bec court **German**: Kurzschnabelbülbül **Spanish**: Bulbul Piquicorto
Other common names: Short-billed/Spectacled Greenbul



Taxonomy. *Bernieria zosterops* Sharpe, 1875, Madagascar.

Relationships of genus with rest of family uncertain. Genus previously merged with *Bernieria*, but recent mitochondrial DNA sequence data indicate that the five species then involved are not a monophyletic group. Hence, this species and its relatives better placed in present genus. Thought probable, on basis of similarities in plumage pattern, that present species is most closely related to little-known *X. tenebrosus*. Proposed races *andapae* (Andapa) and *ankafanae* (Ankafana Forest, in Fianarantsoa) are poorly differentiated, and thus treated as synonyms of nominate. Two subspecies recognized.

Subspecies and Distribution.

X. z. fulvescens (Delacour, 1931) – Montagne d'Ambre, in N Madagascar.

X. z. zosterops (Sharpe, 1875) – E & SW Madagascar (Manongarivo and Tsaratanana Massif S to Tolagnaro, also isolated population at Analavelona).

Descriptive notes. 16–16·5 cm; male 16–20·5 g, female 13·5–22·5 g. A small species with distinctive face pattern, lower mandible slightly inflated centrally and thus appearing somewhat upcurved distally, long rictal bristles. Nominate race is bright olive-green above, tail and wings darker brownish-olive, leading edges of flight-feathers yellow; yellow strip on lores from base of bill to upper half of eye, where contiguous with upper part of wide, well-defined, conspicuous broken yellow eyering; preocular area below loral line (from base of lower mandible to front edge of eye) and onto cheek dark olive, ear-coverts slightly paler olive-green; chin, throat and malar area bright yellow, contrasting with dark preocular patch; breast and flanks olive-green, belly and undertail-coverts yellow; iris mid-brown, dark brown or chestnut; upper mandible brown with yellow cutting edge or completely black, lower mandible light brown, pale yellow-brown, yellow, orange-yellow or pinkish-brown; legs greyish-pink to greyish-yellow, orange-pink or pale flesh, claws pinkish-grey or yellow. Differs from *Bernieria madagascariensis* in smaller size, much shorter bill, yellow "spectacles". Sexes alike, female on average smaller than male. Juvenile has less distinct spectacles, duller throat. Race *fulvescens* is paler and greyer above, and whiter and less yellow below than nominate. VOICE. Quite loud, high-pitched seeping and twittering noises, resembling those of congeners but unlike those of *B. madagascariensis*. Call a high-pitched, rather hoarse, unintrusive "tsit", repeated irregularly, also spluttered "ptrrr"; song an irregular descending series of similar notes.

Habitat. Primary evergreen forest from sea-level to 1500 m, but much less common at higher altitudes; published record from 1800 m requires confirmation. Enters second growth where close to undisturbed forest.

Food and Feeding. Arthropods, including beetles (Coleoptera), termites (Isoptera), earwigs (Dermaptera), bugs (Hemiptera), ants (Hymenoptera), orthopterans and spiders (Araneae). Gregarious; usually occurs in groups of up to 20 individuals, frequently in monospecific flocks, but often in company with *Bernieria madagascariensis*, White-throated Oxylabes (*Oxylabes madagascariensis*) and other species in mixed flocks. At dusk often encountered in single pairs, suggesting that foraging flocks disperse prior to roosting. Forages 0·5–5 m above ground level, hence on average lower than *B. madagascariensis*. Not shy. Frequently perches on vertical stems of thin saplings and trees, up which it works rapidly, making short flights to catch arthropods so disturbed. Gleans in particular in vegetation of small understorey shrubs, as well as creepers, ferns, etc.; also sally-gleans insects from, especially, the undersides of leaves.

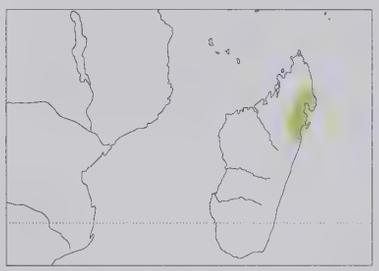
Breeding. Nesting recorded in Sept–Dec. Possibly a co-operative breeder; groups of three adults feeding juveniles. Nest cup-shaped, made of moss, plant stems, dead leaves and other vegetation, typically 0·5–1 m above ground and suspended in a horizontal fork of understorey shrub. Clutch 3–4 eggs; no information on incubation and fledging periods.

Movements. No information; presumed sedentary.

Status and Conservation. Not globally threatened. Generally common throughout its range. Mean densities of 17·5 birds/ha recorded in Montagne d'Ambre and of 552–706 birds/km² in Zahamena. Occurs in numerous protected areas, including Montagne d'Ambre, Marojejy, Masaola, Zahamena, Mantadia-Analamazaoatra, Ranomafana, Andringitra and Andohahela.

Bibliography. Anon. (1999b), Benson & Irwin (1975), Benson *et al.* (1976), Cibois *et al.* (2001), Dee (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Fjeldså *et al.* (1999), Goodman & Benstead (2003), Goodman & Parillo (1997), Goodman & Puttnam (1997), Goodman, Andrianarimisa *et al.* (1996), Goodman, Hawkins & Razafimahaimodison (2000), Goodman, Pidgeon *et al.* (1997), Hawkins (1995, 1999), Hawkins & Goodman (1999), Hawkins *et al.* (1998), Langrand (1990, 1995), Milon *et al.* (1973), Morris & Hawkins (1998), Rand (1936), Safford & Duckworth (1990), Sinclair & Langrand (1998), Thompson & Evans (1991), Thompson *et al.* (1987).

136. **Dusky Tetraka**



Xanthomixis tenebrosus

French: Bulbul obscur **German**: Sianakabülbül **Spanish**: Bulbul Oscuro
Other common names: Dusky Greenbul

Taxonomy. *Bernieria tenebrosa* Stresemann, 1925, Sianaka Forest, central eastern Madagascar.

Relationships of genus with rest of family uncertain. Genus previously merged with *Bernieria*, but recent mitochondrial DNA sequence data indicate that the five species then involved are not a monophyletic group. Hence, this species and its relatives better placed in present genus. Thought probable, on basis of similarities in plumage pattern, that present species is most closely related to *X. zosterops*. Monotypic.

Distribution. NE Madagascar, from at least Marojejy S to Zahamena.

Descriptive notes. 14–15 cm; one unsexed 21·4 g. Small species, dark with yellow throat, robust legs, fairly short bill with lower mandible slightly inflated centrally and appearing somewhat upcurved distally. Plumage is dark dull olive-green above, tail and wings dark dull olive-brown, outer edges of flight-feathers dark green; supraloral area yellow, remainder of face side dark olive-green, conspicuous and contrasting yellow broken eyering; chin, throat and malar area yellow, breast, flanks and undertail-coverts dark olive-green, belly and vent yellow-green; iris mid-brown; bill dull pinkish-orange, dark culmen; legs pale fleshy pink. Differs from similar *X. zosterops* in darker underparts contrasting more strongly with yellow throat, shorter tail, longer, stouter legs and feet. Sexes alike, female on average smaller than male. Juvenile undescribed. VOICE. A series of quiet, high-pitched hissing and twittering calls, similar to those of other members of genus; single contact call a quiet "tseip" or "tsit".

Habitat. Primary lowland and evergreen forest, up to 950 m.

Food and Feeding. Arthropods. Occurs in small groups; sometimes in mixed-species flocks. Largely terrestrial, foraging in areas of often sparse understorey and deep leaf litter; hops rapidly. Sometimes seen in low shrubs, to 0·5 m, particularly when calling. Report of a single individual at 2 m moving through tall branches and clinging to vertical stems seems exceptional, and possibly based upon a misidentification.

Breeding. No information.

Movements. No information; presumed sedentary.

Status and Conservation. VULNERABLE. Restricted-range species: present in East Malagasy Wet Forests EBA. Global population estimated to number fewer than 10,000 individuals. Clearly rare and local, as numerous recent intensive surveys in many forests of E Madagascar, covering wide range of habitats and altitudes, have failed to locate it. Enigmatic; has been widely misidentified in the past, since key identification criteria only recently determined and still poorly understood. Only recent documented records are from Marojejy and Zahamena National Parks; reported also from Masaola, Perinet Special Reserve and Maroantsetra, but without details. Earlier specimen records from elsewhere, including the Andasibe–Mantadia region, but precise localities and altitudes are not known. Outside protected areas, main threats are from forest clearance for subsistence agriculture, which is most prevalent at altitudes at which present species is known to occur.

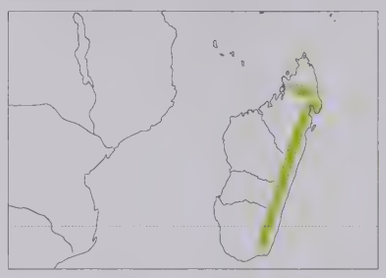
Bibliography. Anon. (1999b), Benson & Irwin (1975), Benson *et al.* (1976), Butchart & Stattersfield (2004), Cibois *et al.* (2001), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Dee (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Fjeldså *et al.* (1999), Goodman & Benstead (2003), Goodman *et al.* (2000), Hawkins (1995, 1999), Jenkins (1987), Langrand (1990, 1995), Morris & Hawkins (1998), Rand (1936), Randriamanindry (1995), Sinclair & Langrand (1998), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

137. **Appert's Tetraka**

Xanthomixis apperti

French: Bulbul d'Appert **German**: Appertbülbül **Spanish**: Bulbul de Appert
Other common names: Appert's Greenbul

Taxonomy. *Phyllastrephus apperti* Colston, 1972, 40 km south-east of Ankazoabo, south-western Madagascar.
Relationships of genus with rest of family uncertain. Genus previously merged with *Bernieria*, but recent mitochondrial DNA sequence data indicate that the five species then involved are not a monophyletic group. Hence, this species and its relatives better placed in present genus. Recent molecular data indicate that present species is sister of *X. cinereiceps*. Monotypic.
Distribution. Zombitse and Vohibasia forests (near Sakaraha) and Analavelona forest, in SW Madagascar.



Descriptive notes. c. 15 cm; 11–17 g. A smallish, slender, distinctively patterned species, narrow bill with lower mandible slightly inflated centrally. Top of head and neck are blue-grey, upperparts, including tail, greenish olive-grey, wings slightly darker, narrow pale yellow fringes on edges of flight-feathers; buffish-white to pale grey supercilium well defined in front of eye, indistinct behind; grey eyestripe dark on lores, paler and less distinct behind eye, blue-grey ear-coverts; eyering pale whitish-grey above and below eye, dark grey in front of and behind eye, blending with supercilium, eyestripe and pale grey cheeks; chin, throat and malar area white, underparts warm yellow, brightest on flanks, centre of belly whitish; iris dark brown; bill dirty pale pink basally, most of upper mandible dark, distal third of lower mandible sometimes also dark; legs pale horn or pale reddish. Sexes alike, female on average smaller than male. Juvenile undescribed. Voice. Call a high, shivering "tsee" or "tseetsee", similar to that of *X. cinereiceps*; also high-pitched alarm, "tsirr".
Habitat. Deciduous forest at 600–800 m, and a tract of relict evergreen forest on isolated massif at 900–1330 m.
Food and Feeding. Arthropods. Occurs in small groups of 2–8 individuals, occasionally singly; sometimes in mixed-species flocks with *Bernieria madagascariensis*. Forages in low dense understorey, rarely above 1 m; often walks on the ground, with wings drooped, gleaning insects from leaves, branches and leaf litter. Perches in low bush when disturbed. Reported also as rising up to 5 m, and as clinging to liane tangles.
Breeding. No information. Subadult recorded in Apr.
Movements. No information; presumed sedentary.
Status and Conservation. VULNERABLE. Restricted-range species: present in West Malagasy Dry Forests EBA. Very rare and highly localized; population within tiny range estimated to number fewer than 2500 individuals. Known only from a tiny part of Zombitse-Vohibasia National Park and, c. 50 km W of there, the unprotected Analavelona forest. Zombitse and Vohibasia forests were threatened mainly by clearance for maize cultivation and charcoal production; following conservation efforts, including the creation of the national park, there has been no further clearance for several years. Analavelona forest is not managed for conservation, but is relatively isolated and clearance is not thought an imminent threat.
Bibliography. Anon. 138. Grey-crowned Tetraka

Xanthomixis cinereiceps

French: Bulbul à tête grise **German**: Grauscheitelbülbül **Spanish**: Bulbul Coronigrís
Other common names: Grey-crowned Greenbul

Taxonomy. *Oxylabes cinereiceps* Sharpe, 1881, Fianarantsoa, Madagascar.
Relationships of genus with rest of family uncertain. Genus previously merged with *Bernieria*, but recent mitochondrial DNA sequence data indicate that the five species then involved are not a monophyletic group. Hence, this species and its relatives better placed in present genus. Recent molecular data indicate that present species is sister of *X. apperti*. Monotypic.
Distribution. NW & E Madagascar (Manongarivo and Tsaratanana, and from Marojejy S to Andohohela).

Descriptive notes. c. 14 cm; 13·5–24·5 g. A small, neat, plain-faced species with few distinguishing features, lower mandible slightly inflated centrally and appearing somewhat upcurved distally. Top of head is blue-grey, mantle and back olive-green, wings and tail slightly darker olive-green, leading edges of flight-feathers with dull pale yellow fringes; lores usually pale greyish-brown, cheeks and ear-coverts blue-grey with some indistinct narrow paler shaft streaking; throat dirty white, breast and belly yellow, darker olive-yellow on sides of breast, flanks and undertail-coverts; iris dark brown or mid-brown; upper mandible dark horn or black with grey cutting edge, lower mandible pale pink or pinkish-grey with dark horn or black tip; legs mid-grey or pale greyish-flesh. Sexes alike, female on average smaller than male. Juvenile is uniform grey-green above, dull buffy below with slightly paler throat; later becomes more grey-tinged on crown, with slightly yellow-tinged underparts and whitish-yellow throat, gape orange. Voice. Song, from shrub-layer perch, a series of spluttering and seeping notes; call a series of single or multiple high-pitched "tsip" notes and spluttering trills.
Habitat. Montane evergreen forest between 800 m and 2000 m, mostly above 1000 m and, usually common only over 1400 m. Not found in disturbed forest.
Food and Feeding. Thought to be mainly insectivorous. Occurs singly or in pairs, often in association with other species, including with *X. zosterops* (where altitudinal ranges overlap) and Wedge-tailed Jery (*Hartertula flavoviridis*). Forages mainly at 0·5–15 m, particularly on vertical moss-clad tree trunks and branches (diameter 2 cm to 1 m), which it climbs nimbly, rather in manner of a nuthatch (*Sitta*). Moves between trunks with strong undulating flight, landing near base and working upwards. Also searches in small shrubs among twigs, occasionally leaves, and on the ground and moss-covered stones. Specialization of foraging on moss-covered trunks is strong, and may explain why this species is rare or absent below 800–1000 m (only limited moss growth at lower altitudes).
Breeding. Nesting recorded in Nov and juveniles in Nov–Dec. May be a co-operative breeder; record of three adults feeding two chicks at single nest. Nest bowl-shaped, depth 5–7 cm, made exclusively of moss, lined with dry grass and palm fibres, built 1–2 m above ground in horizontal fork of small branch. Clutch 3 eggs; no information on incubation and fledging periods.
Movements. No information; presumed sedentary.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in East Malagasy Wet Forests EBA. Fairly common in parts of its range. Thought to have a fairly small population as a result of its restricted altitudinal range, and potentially to be threatened by forest loss from subsistence agriculture. Occurs in a number of national parks and other protected areas, including Marojejy, Mantadia, Ranomafana and Andohohela.

Class AVES

Order PASSERIFORMES

Suborder OSCINES

Family CHLOROPSEIDAE (LEAFBIRDS)

- Medium-sized, arboreal passerines with proportionately short tarsus and toes, small rictal bristles, straight to lightly decurved bill, and channelled, brush-tipped tongue; plumage green, variously with areas of shining blue, black, yellow and orange.
- 14–21 cm.

- Oriental Region.
- Lowland rainforest to monsoon and montane forests, some extending to secondary growth and orchards.
- One genus, 11 species, 27 taxa.
- One species threatened; none extinct since 1600.

Systematics

The only chloropseids known are the leafbirds that are alive today. This group was introduced to science by an eighteenth-century painting that, in 1789, supplied the basis of J. F. Gmelin's description of "*Turdus cochinchinensis*", recognized as being the Blue-winged Leafbird (*Chloropsis cochinchinensis*).

Baron G. Cuvier seems to have been aware of the brush-tipped structure of the leafbird tongue, and in his *Règne Animal*, published in 1817, he used this character to align *cochinchinensis* with the friarbirds (*Philemon*), a genus of meliphagid honeyeaters. The later authors of the entity *Chloropsis* knew about it, too, and guessed accurately at its function. Apart from indicating similarities to the sunbirds (Nectariniidae), however, they refrained from taking a position, as a rival link had by then been proposed with "*Brachypus*", the so-called short-legged thrushes or, in modern parlance, the bulbuls (Pycnonotidae). Most mid-century systematists opted for Cuvier's alternative, but in India, over the same period, E. Blyth and, after him, T. C. Jerdon championed the bulbul hypothesis, a view that anyone handling a live leafbird might even now support, given the bird's general "jizz", body proportions, and such clues as the ease with which feathers of the back and rump are shed, as though deliberately autotomized. Blyth is also the first author to have linked the leafbirds with two other small Oriental groups, the ioras (*Aegithina*) and the fairy-bluebirds (*Irena*), in a special subfamily of the Pycnonotidae. Shortly thereafter, perceptions of the family Pycnonotidae changed. By the 1860s, it was considered to be timalioid and to contain not only bulbuls, but also many genera of what are now called babblers (Timaliidae). Indeed, rather than linking *Chloropsis* with any strictly bulbul genus, G. R. Gray, in 1869, placed it next to *Myzornis*, a monotypic babbler, chosen, no doubt, for its tongue morphology and its green colours.

A decade later, in the influential *Catalogue of the Birds in the British Museum*, R. B. Sharpe pushed this position still further, treating leafbirds, ioras, fairy-bluebirds and bulbuls as actual timaliids, united in a special subfamily, the Brachypodinae. Over most of a century thereafter, the leafbirds and the ioras remained linked, at times together with the fairy-bluebirds and at others without them, as genera once again of a family Pycnonotidae or, on evidence of jaw musculature, as a tribe of a subfamily Pycnonotinae of a greatly expanded Sylviidae. Alternatively, they were hived off to a small family of their own, as was proposed in 1927, "for convenience", by H. C. Robinson. In his 1960 text for J. L. Peters's *Check-list of Birds of the World*, J. Delacour opted for an inclusive Irenidae, next to bulbuls, although he may not by then have considered osteological characters, including those of the palate, that, in the view of A. Wetmore, permitted a continued connection between leafbirds and ioras but distanced these two from the bulbuls, and still further from the fairy-bluebirds. Despite what was by that time a growing opinion among field observers that living leafbirds and ioras exhibited no obvious features in common, one or other of these arrangements held sway until the era of molecular taxonomy.

While the systematic position of leafbirds in relation to other families has taken well over a century to decode, and still awaits conclusive resolution, the relationships within the family are hardly less complex. For example, the ***Blue-winged Leafbird*** *was until recently considered conspecific with Jerdon's Leafbird* (Chloropsis jerdoni) *and the Bornean Leafbird* (C. kinabaluensis)*, but the three are now deemed worthy of separate species status on morphological grounds. Meanwhile, the morphological differences separating Sumatran birds (sometimes placed in* icterocephala*) from continental birds seem insignificant, and the two are commonly merged within* moluccensis.

[*Chloropsis cochinchinensis moluccensis*, Way Kambas National Park, Sumatra. Photo: Tony Tilford]

*This male **Greater Green Leafbird** demonstrates several features typical of the family. First, and perhaps most obviously, it is bright green, a relatively unusual colour for passerines, but excellent camouflage in leafy canopies. Next, it has short robust legs, appropriate tools for an arboreal lifestyle. Finally, it has a black mask, highlighted by a paler surround, and a violet-blue jawline streak, just discernable in this photograph, but much more conspicuous when the blue feathers are erected. This species, the largest of all leafbirds, has the strongest, most distinctly hook-tipped bill in the family.*

[*Chloropsis sonnerati*. Photo: Konrad Wothe]

From DNA–DNA hybridization findings, C. G. Sibley and J. E. Ahlquist, in their 1990 publication on the phylogeny of birds, upheld the birdwatchers' view and severed the iora connection, leaving the leafbirds linked once more with the fairy-bluebirds, near the base of their "parvorder" Corvida. More recent base-sequence analysis of nuclear-gene DNA by F. K. Barker and colleagues supports this separation from ioras; indeed, it widens it decisively by transferring the leafbirds and the fairy-bluebirds entirely out of Corvida and into Sibley and Ahlquist's other "parvorder" of the oscine passerines, Passerida. Both approaches treat these two groups as constituting one family, although it seems that a case in support of linkage at that level has still to be made. The decision not to accept it in the present work is provisional. Either way, no close connection between the leafbirds and the bulbuls, babblers, honeyeaters or ioras survives. Instead, the chloropseids emerge as the sister-group of an enlarged family Passeridae, nested within the fairy-bluebirds and, ultimately, the sunbirds.

Delacour's review of the leafbirds accepted eight species, many fewer than were recognized by Sharpe in his *Catalogue*. Currently, eleven are recognized, more than on Delacour's list but by no means signalling a return to nineteenth-century practice. The technical explanation of this revision was published by D. R. Wells and co-workers in 2003. Essentially, it repairs a gap in Peters's *Check-list*, and applies assumptions concerning species limits that question certain mid-twentieth-century acts of lumping. The overlooked taxon is *Chloropsis kinabaluensis*, the Bornean Leafbird. This species, formerly known as *flavocincta*, is endemic in upland forests of Borneo and was for many decades treated as a subspecies of the widespread lowland Blue-winged Leafbird. As with most leafbird species, males of the latter have a black facial mask and throat, whereas females do not, implying that this difference acts in sexual recognition (see Morphological Aspects). The only non-black-faced stages of *kinabaluensis*, on the other hand, are juvenile, disrupting a signal that might facilitate matings between these taxa. Further differences between Bornean and Blue-winged Leafbirds include other obvious plumage characters, measurements, size dimorphism and bill morphology. There is no record of intergradation between the two, even though their ranges in continuous habitat meet parapatrically or are separated by only a short span of altitude.

If the criterion of an equivalent amount of morphological divergence is applied elsewhere in Delacour's *Chloropsis cochinchinensis* complex, the fully allopatric Indian taxon *jerdoni* must also be split off as a separate species, Jerdon's Leafbird (*Chloropsis jerdoni*). This leaves a still polytypic but shrunken, morphologically much better-integrated species occupying just the South-east Asian lowland heartland of the family, extending west to Assam. As full species, potentially, these two and the Bornean *kinabaluensis* still form a superspecies. The allopatric Yellow-throated Leafbird (*Chloropsis palawanensis*), blue-winged but with no black at all on the head, is a reasonably safe fourth member of that superspecies, and the even more extensively hen-plumaged Philippine Leafbird (*Chloropsis flavipennis*) of elsewhere in the Philippines a far less certain fifth. The latter's only suggestive link (but see Voice) is the similarity of the yellow wing pattern to that of the geographically distant Jerdon's Leafbird.

Elsewhere in the family, these same arguments have been applied to the Sumatran taxon *media*, considered since Delacour's review as a remote subspecies of the Golden-fronted Leafbird (*Chloropsis aurifrons*), a species that otherwise no longer enters the Sunda region. Males of *media* exhibit a typical black mask and throat but females do not, whereas, throughout the continental range of *C. aurifrons*, both sexes have these areas of the plumage black, with only juveniles being entirely green-headed. This situation mirrors that of the Blue-winged and Bornean Leafbirds, and forces the same conclusion, albeit without the parapatry element. From their undoubted connection via other characters, it follows that the Sumatran Leafbird (*Chloropsis media*) and the restricted Golden-fronted Leafbird should also be treated as forming a superspecies.

Morphological Aspects

Chloropseids range in size from the Blue-masked Leafbird (*Chloropsis venusta*), with a wing length of 68–72 mm, males unlikely to weigh more than 15 g and females probably less, to the Greater Green Leafbird (*Chloropsis sonnerati*), with male wing length up to 105 mm and weight up to 48 g. Almost as long-winged but not quite so heavy are outer-tropical representatives of the Golden-fronted and Orange-bellied Leafbirds (*Chloropsis hardwickii*).

Only in the inner South-east Asian tropics do three or more taxa co-occur all year round. These are typically well spaced over the family spectrum of size or, where overlap occurs, as between the Lesser Green (*Chloropsis cyanopogon*) and Blue-winged Leafbirds in lowland forests of the Sunda region, they focus on

*Sexual dimorphism in plumage reaches its peak amongst leafbirds in the **Orange-bellied Leafbird**. The gaudy male, perhaps the most spectacular member of the family, is pictured here alongside his relatively sombre mate. Males combine a melodious song with a pleasing assortment of colours, including black and violet-blue on the face, bronzy-yellow on the nape, brilliant electric blue on the wings, tawny orange on the belly, and grass-green on the mantle, making them very popular in avicultural circles. In at least some races, conversely, the female is a dowdy creature, little sought-after as a cage-bird, and often passed over in the field.*

[*Chloropsis hardwickii*. Photo: Cyril Laubscher]

different parts of the habitat. On the forested submontane slope of the Sumatran Barisan Range, uniquely, as many as five species could meet. These span the extremes of size, but the Greater Green Leafbird and the almost equally large Sumatran Leafbird are presumed to differ in some aspect of ecology still to be researched.

Beyond that, all chloropseids are, at a glance, obvious leafbirds. Overall shape and proportions seem standard, and the "leaf" part of the vernacular name denotes predominant to near-complete greenness of the plumage. Among species, and some subspecies particularly of the Blue-winged Leafbird, colour tone ranges from bright shades of grass-green or emerald-green to, especially on the underparts, yellowish-tinted or viridian-tinted green. All supply highly effective camouflage to the birds while they forage or are brooding on nests amid canopy foliage, although seasonally much less, of course, to the few populations of Jerdon's and Golden-fronted Leafbirds that inhabit deciduous forest.

Relieving colours and patterns are limited, but spectacular. In all except the Philippine Leafbird and the female Bornean Leafbird, adults of both sexes develop a semi-erectile jawline flash of glistening turquoise to violet-blue or rich cobalt-blue, varying according to species. This flash of colour is usually larger on males, and in some, but not all, subspecies of the Golden-fronted Leafbird it covers the whole of the chin and upper throat. Acquired at post-juvenile moult, this feature has no precursor and must signal sexual maturity.

Again excluding the Philippine Leafbird, and in this instance also the Blue-masked Leafbird, the green colours of adult males are relieved by a patch of iridescent viridian or turquoise to clear blue over the inner leading lesser upperwing-coverts. Hidden when the bird is relaxed, this patch is exposed during aggressive encounters, in certain courtship postures, and at take-off. In several species, an only slightly smaller or less brilliant patch is also present on adult females. Both sexes of all subspecies of the Blue-winged Leafbird, and both sexes of the Bornean Leafbird, have such a patch, in these cases greatly expanded out over the carpus, alula and primary coverts and the outer webs of most flight-feathers; it is boldly visible in the closed wing. The tone of the exposed part varies geographically, from bright aquamarine to a mixture of clear and deep, rich cobalt, the latter occurring in the Sunda region. Interestingly, the Bornean Leafbird differs sharply from the Bornean race of the Blue-winged Leafbird in this respect. The related, island-living Yellow-throated Leafbird retains almost as much blue, although of a rather duller tone, and both sexes of these three species also have an extensively blue tail. The only near-parallel development of blue in the wing occurs in the adult male Orange-bellied Leafbird, and the female of this species shows a little blue in the tail, which is deep black with dark purplish-blue edges in males. Uniquely, both sexes of the little Blue-masked Leafbird have a light blue anterior cap and ear-coverts, the adult female also has the chin and throat blue, and both show blue on the tail; males have an additional bright blue flash on the leading edge just of the carpus.

A better-known plumage variable is the mask, typically enclosing the side of the face up to the level of the lores and the middle of the eyes, and the chin to the throat or upper breast, hence also enclosing the blue jawline flash. The mask is velvety black in all chloropseids except the Blue-masked Leafbird, in which the only dark part is deep brown and it is limited to the chin and throat. All adult males other than those of the two Philippine endemics exhibit it, as also do adult females of the surely unrelated Golden-fronted and Bornean Leafbirds. Whatever its main signal function, the mask presumably aids the recognition at least of maturity; in the case of the rainforest-dwelling Greater Green and Blue-winged Leafbirds, moreover, random variation in shape and size of the bib part implies that it may even assist the identification of individuals. In all taxa, the mask form is accentuated by the brilliance of juxtaposed colour: turquoise or brilliant green or, in the Golden-fronted, Sumatran, Blue-masked and Blue-winged Leafbirds, and narrowly in a subspecies of the Lesser Green Leafbird, a partial or full surround of contrast-heightening yellow to golden-yellow or orange. This reaches an extreme in some Sunda region subspecies of the Blue-winged Leafbird, in which most of the rest of the head is bright yellow. Reduced amounts of similar colours recur in the females of some of these species, and the otherwise mostly green females of several others show a yellow forehead, throat and/or eyering, such patterns being found as well in both sexes of the two maskless Philippine species.

Juveniles show the least colour relief, with never a trace of a mask or jaw flash and, otherwise, not more than a subdued expression of adult female plumage. Some are featurelessly green, to an extreme extent in the Orange-bellied Leafbird, which, as an adult, is arguably the gaudiest of all members of the family.

*Most members of the family, including the **Golden-fronted Leafbird**, deliver powerful songs, often from perches in the uppermost canopy. These outpourings tend to be varied and sustained, containing liquid warbles, resonant notes, repetitions, and a great deal of mimicry. In general, they are easily assigned to the family, but not to its constituent species, in part because so little use is made of species-specific elements. It is tempting to conclude that, like most mimetic oscines, repertoire size is an important sexual signal. If this is shown to be the case, the system incorporates an extra layer of complexity as, in at least some species of leafbird, both sexes sing.*

[*Chloropsis aurifrons*. Photo: Roland Seitre]

Leafbirds are often cited as ardent nectarivores. As it happens, this habit varies regionally and cannot be applied to all members of the family; it is standard practice in the Indian Subcontinent, for example, but noted much less often in South-east Asia, where leafbird diversity reaches its peak. Attendance at flowering trees is most common in three species with bills that are relatively slender, pointed and decurved, and with brush-like tongues that are relatively long; one of these is the ***Golden-fronted Leafbird****. While these birds are well designed for the task of nectar gleaning, most leafbirds probably harvest nectar only occasionally.*

[*Chloropsis aurifrons aurifrons*, Kaziranga National Park, India. Photo: Gertrud & Helmut Denzau]

Only a few really clear evolutionary trends emerge from this detail. One is that the Philippine Leafbird, probably long isolated on a few islands of the southern Philippines, has taken the classical oceanic-isolate route of reducing sexual dimorphism through loss of ornamentation; indeed, with its lack of a contrasting jawline flash, it could even be said to be neotenic. The Yellow-throated Leafbird, alone in the western part of the Philippines, is on its way to losing plumage ornamentation, but it still retains features that link it with its more typical Asian relatives. The inference here is that, in some lines at least, male ornamentation carries, or has carried, a fitness cost. Parsimony, backed by the weight of species numbers, would then interpret female masklessness and the universal plainness of juveniles as ancestral in the family. If this is so, cock-type plumage among females is a derived character, evolved independently in offshoots of what appear to be two different superspecies.

Among strictly maintenance characters, the authors of the genus *Chloropsis* mentioned variation in bill shape. This seems then to have been forgotten, but it is real and unexpectedly informative. Jerdon's, Golden-fronted and Orange-bellied Leafbirds and, to a less obvious extent, the Blue-masked Leafbird all have a bill that is more than ordinarily long and slender, is lightly decurved along both profiles, and has the upper cutting edge smooth throughout, with the mandibles tapering to meet precisely, tip to tip. In most other taxa, the bill is proportionately heavier, and straight to very slightly recurved along the lower profile, while the cutting edge of the upper mandible is obviously notched near its tip, with a prominent nail that curves or hooks beyond the tip position of the lower mandible. The Sumatran Leafbird only just fits into this second camp, and the Blue-winged Leafbird alone is properly intermediate, with a minute notch and barely noticeable nail development.

Drawn thus, bill-type boundaries cut through proposed superspecies. For example, the heavy-billed, nail-tipped Bornean Leafbird is particularly different from its Blue-winged Leafbird neighbour, and the bills of both maskless species are conspicuously nailed, the Philippine Leafbird's bill being as prominently hook-tipped as that of the powerful Greater Green Leafbird. Either adaptations for foraging have been plastic in leafbirds, or chloropseid taxonomy above species level requires re-examination.

Bill-shape variations imply differences at least in foraging emphasis, with some associated variation to be expected in, say, tongue morphology. Specimens of seven species, however, showed this not to be the case. These were the Golden-fronted, Orange-bellied and Jerdon's Leafbirds in the slender-billed category, the nail-billed Greater Green, Lesser Green and Yellow-throated Leafbirds, and the intermediate Blue-winged Leafbird. All showed essentially one tongue type: dorsally concave, or channel-sectioned, with the tip produced into a keratinous brush lying in the concavity of the outer lower mandible. Two features varied. The first of these was the length of the brush beyond the extreme fleshy tip of the tongue, being close to 6 mm and 8 mm respectively in the Golden-fronted and Orange-bellied Leafbirds, 4·6 mm in Jerdon's, 3·5 mm in the Blue-winged, and 2·2–4·4 mm in the rest, up to the size of the Greater Green Leafbird. The second was the projection of the horns of the hyoid support of the tongue, lying free over the base of the braincase; they reached far up the rear of the skull in Golden-fronted and Orange-bellied Leafbirds, but over only its basal quarter in the rest. These differences are taken up again below (see Food and Feeding).

Habitat

Other than arid-zone thorny acacia (*Acacia*) woodland, all the major divisions of natural broadleaf forest in the Oriental Region that support well-grown trees harbour one or more leafbird species. In inner tropical South-east Asia this extends even to the landward, or "back", zones of mangrove forest, although, in recent decades, most of that particular habitat has been lost to new land uses. So far as altitude is concerned, the Orange-bellied Leafbird occurs to 2400 m in the eastern Himalayan foothills and Yunnan, and to at least 2000 m elsewhere in south China, at which elevation broadleaf forest overwinters deciduously, forcing affected populations to migrate downslope. At lower latitudes, this species ranges to much the same upper altitudinal limit, but in more equable, evergreen conditions that are inhabitable throughout the year. In Peninsular Malaysia, it reaches 1900 m and stays entirely within montane forest. Neither the Bornean nor the Blue-masked Leafbird, the mountain chloropseids of Borneo and Sumatra, respectively, is known to range as high as does the Orange-bellied Leafbird, even though equivalent tall forest is open to them on both of these islands.

All members of the family eat fruit, with figs and soft-fleshed berries being the main target. Although small items are swallowed whole, some leafbirds have been recorded using a distinctive fruit-processing technique for medium-sized berries. First, these are speared on the lower mandible and rotated. Then, as seen in the accompanying photograph, they are squeezed in the bill. After the loosened contents are sucked in, the rind is discarded. It is likely that the grooved and brush-tipped tongue assists in channeling fluids into the throat. In addition, the closed bill tip of the ***Orange-bellied Leafbird****, amongst others, has a U-shaped groove through which the tongue protrudes.*

[*Chloropsis hardwickii malayana*, Fraser's Hill, Malaysia. Photo: Ong Kiem Sian]

Seasonal, monsoon forests of the plains and lower slopes in south and outer South-east Asia that are quasi-deciduous to fully deciduous hold Golden-fronted Leafbirds and, in India and Sri Lanka, also Jerdon's Leafbirds, the latter veering towards drier, more open habitats and showing a greater preference than does the Golden-fronted for edge and disturbed conditions. There are also populations of Golden-fronted Leafbirds that live in near-evergreen forest, and in and eastwards from the far north-east Indian Subcontinent Golden-fronted and Blue-winged Leafbirds share a set of lowland and submontane forest habitats that have a greater humidity than is tolerated by Jerdon's Leafbird. Breeding habitats are partitioned by altitude but, seasonally, probably all three species make some contact as well with non-breeding Orange-bellied Leafbirds, the latter descending to lower elevations in winter. From as far east as north Vietnam, records exist of groups of two or more of these species merging at an occasional source of food that they had in common.

Southwards, all lowland South-east Asian chloropseids are inhabitants of evergreen forests, from mature, with a closed canopy, to those that are selectively disturbed but still retain much tall timber. Probably, all range out temporarily into well-grown secondary forest, wooded gardens and small clearings in the vicinity of the original stand, but in the Sunda region only the Blue-winged Leafbird makes priority use of edge and secondary conditions. The Greater Green Leafbird reaches lowland freshwater swamp-forest, and this is the leafbird formerly found in back mangroves. Towards the upper limits of their ranges, these species and others all approach the ecotone with montane forest. Locally, and for a short distance, especially where disturbance has occurred, they may cross it.

No member of the family forages or nests in narrow-leafed conifers, although Sumatran Leafbirds were collected from a small patch of broadleaf vegetation isolated within a forest of the pine *Pinus merkusii*.

General Habits

In whatever type of woodland or forest they happen to occupy, leafbirds live at canopy level, right at the foliage "skin" and up to the very pinnacle of emergents, the latter being a favoured songpost of the Orange-bellied Leafbird and others. They obtain all food and fluids aloft, and they also bathe there, using, where available, water cupped into a rotted-out bough end or knothole. Only under drought conditions, or in occasional pursuit of some large arthropod dropping out of high foliage, do they make brief visits to the ground. Not surprisingly, as a consequence of this canopy-dwelling lifestyle, the general behaviour of this family is relatively little known.

Probably all leafbirds disperse to breed, and they may then behave territorially, if only in respect of some temporary food source. H. C. Smith recounts an observation of his in north Myanmar, when two male Golden-fronted Leafbirds actually fell to earth while locked in combat. On the other hand, widely in south Asia and through the northern outer tropics non-breeding Jerdon's, Golden-fronted, Orange-bellied and Blue-winged Leafbirds have all often been described as forming parties that forage socially; one report from Sikkim, by S. Ali, was of over 50 Orange-bellied Leafbirds together in a flowering *Bassia* shrub. As stated, such gatherings occasionally include more than one species. Scraps of information published on the Sumatran and Blue-masked Leafbirds imply that, at times, these southern island endemics, too, forage socially, in groups likely to be larger than family parties, although confirmation of just about any aspect of the behaviour of this under-observed pair in the wild would be welcome.

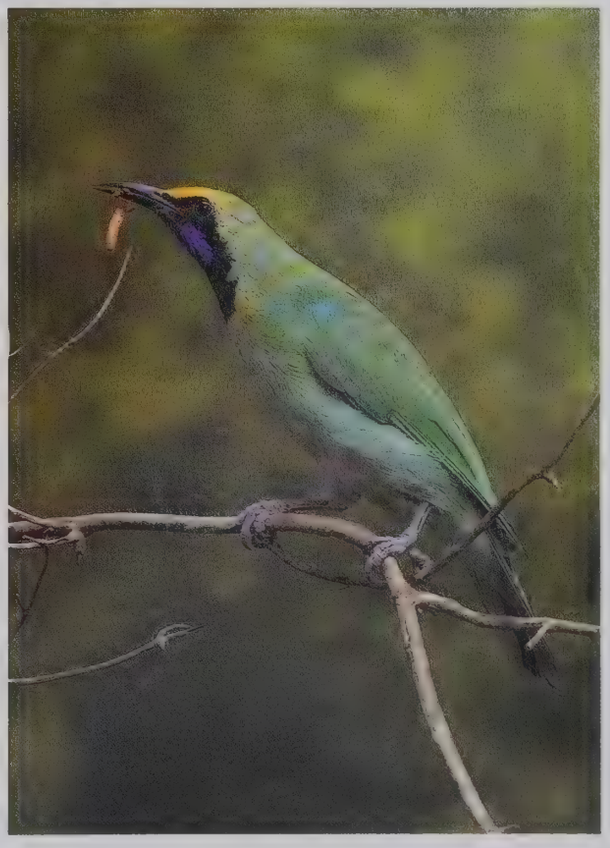
With potential exceptions in upland Sumatra, the growing impression is of a broad behavioural divide between the leafbirds of western and northern parts of the family's range and those of humid forest environments of inner tropical South-east Asia, including the Sunda region. There, the typical social unit while foraging, at all times, comprises one bird or a pair, but never more than a potential family party, and this applies equally to low-latitude populations of the widespread Blue-winged Leafbird. Among lowland species visiting fruiting shrubs in a clearing of Pasoh Research Forest, in Peninsular Malaysia, A. Coates observed an adult male Blue-winged Leafbird as it aggressively defended a small fruiting shrub against conspecifics of all age/sex-classes, and noted that individual male Greater Green Leafbirds systematically chased away all other leafbirds of all species. The Orange-bellied Leafbird, the second widespread, di-

Like most leafbirds, ***Jerdon's Leafbird*** *is a generalist, consuming large numbers of insects, but augmenting them with fruit and nectar. The insect portion of the diet is often sought acrobatically in leafy canopies, while nectar is taken from a variety of flowers. Indeed, non-breeding individuals are known to trap-line nectar sources in groups. Amongst the flowers visited by Jerdon's Leafbirds are those of the coconut palm* (Cocos nucifera)*, pictured here, a plant which is grown commercially in abundance throughout much of south India and Sri Lanka.*

[*Chloropsis jerdoni*, Sri Lanka. Photo: Greg Dean]

vide-crossing species, has made a similar behavioural shift on the Malaysian mountains, where no forager gatherings are known and where the arrival of extra birds, especially adults, in a pair's activity space always generates much agitation, song and aggressive posturing. As an inevitable exception, a group of seven Bornean Leafbirds encountered together on Mount Mulu, in Sarawak, bends this "rule", but still the party included only two black-masked adults. With this species, too, loners or a pair are the foraging norm.

Voice



Those chloropseids that are confined to South-east Asian islands, constituting about 40% of leafbird species, are almost unknown vocally, at least in the wild. All the rest are rich, relatively powerful singers, their sustained outputs, containing liquid warbles, strident, resonant inflections and numerous doublings, being fairly easily marked down to family by an experienced listener. At species level, the story is different. Beyond comparing generalized pitch, "sweetness", stress, duration, and the like, no ornithologist appears yet to have found a way of separating leafbird songs succinctly and dependably by means of their structure. More to the point, no two genuinely independent transliterations of the songs of a given species seem ever to match more than vaguely, unless taken from the same localized population, and even then matches can be loose. It follows that descriptions in the literature, copied on, as they often are, from source to source, have limited value as tools in field identification.

This difficulty is explainable in two steps. The first is the exceptional capacity of leafbirds to mimic, an ability that, as aviculturalists keeping such species as Golden-fronted and Orange-bellied Leafbirds have long known, is carried into adulthood and, in captivity at least, extends beyond avian models. The second is the guess that, even by higher-passerine standards, very few song elements of chloropseids are hard-wired. Apart from sound quality and general rhythmic structure, evidently, song is acquired by copying not just the vocalizations of the parental generation but also sounds from the acoustic environment in general. Leafbird songs, often prolonged, complex, and returning to a particular motif only at intervals, are perhaps mostly mimetic, built up selectively over time to the point at which they may well be recognizable individually. What kind of sexual or other selective advantage is accrued by this has not been investigated, and the matter is complicated by the fact that, in the case of the Orange-bellied Leafbird and almost certainly some others, both sexes, including pair-members, sing.

"Selectiveness" of mimicry is open to subjective assessment by observers impressed by the leafbirds' reproduction of cer-

Large leafbirds with nail-tipped bills are capable of capturing locust-sized orthopterans and mantids, but those species with finer, hookless bills, such as the ***Golden-fronted Leafbird****, are restricted to smaller fare. Their invertebrate intake is largely made up of caterpillars, other insect larvae and spiders. In addition, when winged prey such as lepidopterans are flushed, these are often pursued in short aerial sallies, as are swarms of alate termites emerging en masse after rain. Larger insects are subdued with difficulty, as leafbirds seem not to swipe their prey against branches, but merely to squeeze them rhythmically with the bill.*

[*Chloropsis aurifrons*. Photo: Tony Tilford/Oxford Scientific Films]

Leafbirds tend to place their simple cup-shaped nests near the tips of branches, often suspending them hammock-style from thin twigs in the high canopy. The nest of this ***Jerdon's Leafbird*** *is a rather messy affair, showing little sign of afterthought. In many cases, however, the exterior is swathed in cobweb silk, often with pieces of bark, lichen or bryophyte added as camouflage. Taking the family as a whole, standard clutch size in the tropics is two eggs, with the incidence of three-egg clutches increasing towards temperate regions. In aviaries, eggs hatch 13–14 days after laying, and chicks fledge 12–15 days after hatching, although it is difficult to predict how the duration of these periods is affected by factors such as diet and microclimate, both of which are sure to be somewhat different in captivity as compared with the wild.*

[*Chloropsis jerdoni*, Sri Lanka. Photo: T. S. U. de Zylva/ FLPA]

tain kinds of call, compounded by the copying-on of particular statements in the literature. It is unlikely, for instance, that all Jerdon's Leafbirds make a habit of stirring up the local avian community by uttering precision copies of Shikra (*Accipiter badius*) calls. Nevertheless, some groups of models are mentioned repeatedly, across species, implying that certain types of sound may be copied preferentially. Drongos head this list, with common mention of Black (*Dicrurus macrocercus*) and White-bellied Drongos (*Dicrurus caerulescens*) being mimicked by Jerdon's Leafbird, and the Bronzed Drongo (*Dicrurus aeneus*) by both Golden-fronted and Orange-bellied Leafbirds. A recent report from Fraser's Hill, on the Main Range in Peninsular Malaysia, on the other hand, adds a new and confusing dimension to the story. In this instance, sustained, full-blown song of what was thought to be an Orange-bellied Leafbird was tracked down to a Bronzed Drongo.

It is hardly surprising that the songs of leafbirds are not considered likely to contain much information of phyletic interest. P. C. Rasmussen has suggested that more might be extractable from their various simpler contact calls, and this possibility merits further investigation. Attention has been drawn to the similarity of the three-note "trick-or-treat" calls of the allopatric Yellow-throated and Philippine Leafbirds, and to the "chick-weeeep" of the latter species compared with the common "kwip-kweep" contact call of the Blue-winged Leafbird, a potential continental relative. At the same time, one of the mimicked sounds most often reproduced by Orange-bellied Leafbirds in Malaysia, as well as, apparently, in the eastern Himalayas, is the loud "chittik" flight call of the Streaked Spiderhunter (*Arachnothera magna*), commonly given by the leafbird as its own signal at take-off.

Food and Feeding

A cross-checking of sources makes it clear that the leafbird species for which there are reasonable data on foraging feed on animals. In all cases, they glean arthropods from outer-canopy branchlets and foliage, often moving acrobatically in order to counter the weight of the body on thin stems. The Golden-fronted Leafbird is also reported as being able to hover-glean, and another way in which this species and the Orange-bellied Leafbird search for hidden prey is by inserting the slender, nailless (see Morphological Aspects) bill tip between stuck-down leaves and then opening the mouth.

Chloropseid diets comprise spiders and insects. Items taken by the nail-billed species range up to locust-sized orthopterans and mantids or, in the case of the Blue-winged Leafbird, equivalently large caterpillars. The birds subdue the biggest and toughest prey, with difficulty, by working them through the bill, rather than swiping them on a branch. Items flushed by disturbance are chased, in extreme cases down to the forest floor, and they may actually be subdued on the ground, as has been observed for the Greater Green Leafbird. At regular foraging levels, high in the canopy, lepidopterans, winged termites (Isoptera) and similar prey are taken aerially, in short pursuit-flights.

Among the various leafbird species, the shape and size of the bill are presumed to influence prey-capture and prey-manipulating techniques. No diet is documented completely enough to substantiate that for certain, but, interestingly, of the six leafbird species reported as regularly joining mixed-species flocks of foraging insectivores that flush prey by general disturbance, five have a nail-tipped bill.

F. R. Lambert considered that Blue-winged Leafbirds of the Kerau Wildlife Reserve, in Peninsular Malaysia, took figs (*Ficus*) only incidentally, while detouring from mixed flocks of insectivores as these happened to pass close to a crop. This species visited many fewer kinds of fig than did co-occurring Greater and Lesser Green Leafbirds, but all of the better-known leafbird species take significant amounts of fruit, in addition to their animal foods. Figs and small-seeded, soft-fleshed berries are the main target and, once again, bill morphology would be expected to affect the food-handling procedure. In this instance, however, the nail-billed Greater and Lesser Green Leafbirds share a special fruit-processing technique with the Blue-winged, Golden-fronted and Orange-bellied Leafbirds and, as future research is likely to reveal, probably with others. Particularly small items or cuttable pieces of large fruits are swallowed whole, but medium-sized berries are routinely speared on the lower mandible, at the stalk end, and their contents loosened by rotation. The fruit is then clamped and squeezed in the bill, the loosened contents are sucked in, and the empty rind is discarded. With side ridges pressed against the interior of the upper mandible, the brush-tipped, grooved tongue (see Morphological Aspects) is certain to help in channelling fluids into the throat. At least in the Orange-bellied and Golden-fronted Leafbirds, which possess long hyoid horns, the tongue is also known to be protrusible, and is protruded while fruit is being eaten. Further, it so happens that the lower mandible of these two species and Jerdon's Leafbird, but not that of any of the others examined, ends in a fine, open "U" through which a brush tip could pass while the bill is still closed.

This last adaptation introduces the third leafbird foraging element, that of flower-visiting. Claims of the importance, or even the dominance, of nectar in leafbird diets are commonplace in the literature of the southern Asian and outer tropical parts of the family's range. It is regularly asserted, for example, that leafbirds are most often seen at clumps of *Loranthus* mistletoes; that they are inseparable from parasitic *Loranthus*; and that they are found at the blossoms of the plants *Bassia*, *Helicteres*, *Salmalia*, *Erythrina*, *Firmiana*, *Bombax* and *Cocos*. Moreover, H. T. and J. C. Caldwell, in their 1931 book on the birds of south China, relate how every specimen of Orange-bellied Leafbird that they collected in the Fujian uplands was caked around the face with pollen. Flushes of nectar-rich flowers on large crowns in these areas certainly do attract leafbirds, socially, in the non-breeding season, and between sources parties probably practise trap-line feeding. This behaviour has led to assertions, such as that by Ali and S. D. Ripley, that "all [leafbirds] are important flower-birds... responsible for pollinating the blossoms of numerous species of trees and shrubs in their quest for nectar". This statement, although likely to be true, is still an assumption, as indeed is the "quest for nectar", rather than for the insects that nectar attracts. Indeed, it would be an exaggeration to claim that all leafbirds are committed flower-visitors. The behaviour applies to northern populations of the intermediate-billed Blue-winged Leafbird and, without question, to the Orange-bellied, Golden-fronted and Jerdon's Leafbirds, which happen also to be the ones possessing a slenderly pointed, open-tipped bill and a long-brushed tongue; but it relates to these taxa alone.

The ornithological literature on inner South-east Asia, covering a longer list of leafbird species, contains no such statements; indeed, there is barely a mention of flower-visiting behaviour. A pair of Greater Green Leafbirds visited a Bornean *Loranthus* mistletoe and probed its tubular corollas, and in Peninsular Malaysia H. E. McClure recorded instances of Greater Green and Blue-winged Leafbirds at similar blossoms of *Aeschynanthus*, an epiphytic gesneriad of rainforest, which they robbed by puncturing its corolla bases. Both Blue-winged and Lesser Green Leafbirds have also been seen there at inflorescences of the introduced gum *Eucalyptus deglupta*, and in Borneo G. W. H. Davison found Blue-winged Leafbirds at the honey-scented, insect-attracting flowers of *Rhodamnia*, a small forest-edge tree of the same family. These examples come close to the sum of references, from which it appears that the region's leafbirds visit flowers intermittently but are by no means the dedicated nectar birds described above. Apart from the Blue-winged Leafbird and the unstudied Blue-masked Leafbird, of course, they represent the nail-billed section of the family.

Breeding

The breeding habits of three species are reasonably well known. About three others nothing at all is known, and for the remaining five species only a few data are available. Projecting from this partial information, it seems that chloropseids are among the few passerines of tropical forests, at least in Asia, that do not seek to nest in the shelter and relative constancy of micro-climate of the lower shade layer. Their nests are always located towards the outer end of a lateral branch high in the tree crown. This is the normal practice of Jerdon's Leafbird and the Golden-fronted Leafbird, the two species inhabiting more open woodland, and it follows that, in rainforest, some, and perhaps even most, building occurs above the listed 20 m maximum for the family.

It is little wonder, then, that so few nests of leafbirds have ever been found by ornithologists, let alone described in any detail. Those that have been discovered show a uniformity of form and construction. They comprise an open cup, shallow to moderately deep, built from a mixture of fine stems, tendrils, leaf parts and the like, and "rootlets", the last being a term frequently employed to cover a variety of unidentified material that may sometimes include fibrous aerial root parts. The structure is suspended hammock-wise from thin, leafy twigs, including thin prongs of a fork, which pass through the rim; it is felted externally with cobweb, some of which helps to anchor the nest; and is camouflaged with bryophytes and lichens. Only one instance of a different type of nest is on record. This apparently aberrant structure, from north-east India, was an open cup built directly on to the surface of a bough reputedly by a Blue-winged Leafbird.

*The **Yellow-throated Leafbird** is endemic to the island of Palawan, making it a Restricted-range species. Despite this limited distribution, it is not red-listed or even considered Near-threatened because its population is apparently healthy in intact forest and secondary growth. Nevertheless, forest loss on several more developed Philippine islands has been catastrophic, and, if Palawan follows suit, all of its endemic forest fauna will be driven towards extinction. The situation requires monitoring, and reserves that have been established to protect the island's native habitats must be carefully conserved.*

[*Chloropsis palawanensis*, Palawan, Philippines. Photo: Roland Seitre]

*Of all leafbirds, the **Blue-masked Leafbird** is the smallest. The adult male is a spectacular bird, with intense flashes of violet, indigo and aquamarine on the head. The female, pictured here, is rather more subdued. It occupies a relatively narrow elevational band in the Barisan highlands of Sumatra, reaching peak abundance at altitudes around 1000 m, and it seems to be naturally uncommon. Given these facts it is treated as Near-threatened, although it faces no immediate risk because forest in its elevational range remains relatively secure, at least away from roads. Moreover, this species tolerates a certain degree of habitat degradation.*

[*Chloropsis venusta*. Photo: Stan Osolinski/ Oxford Scientific Films]

As far as is known, and in keeping with their aggressiveness, leafbird pairs space themselves out to breed, although most descriptions of reproductive behaviour derive from observation of captive pairs in aviaries. Courting male Orange-bellied Leafbirds fluffed out the dorsal plumage, opened and shivered the wings, exposing the shining blue lesser wing-covert patch, and vocalized, but the calls, unfortunately, are undescribed. Exposing of the wing-covert patch by this and other species also occurs in threat behaviour. Male Golden-fronted Leafbirds performed acrobatically, frequently hanging below the female's perch, and, in Thailand, a courting bird of unspecified sex was observed to crouch while flapping its wings over the back and fanning out its tail. These species, and also a male Sumatran Leafbird, fed their pre-laying mates, and only the females incubated, a hen Sumatran Leafbird starting from the laying of her first egg.

On limited evidence, the predominant clutch size of the family is two eggs, no more than this number having yet been recorded for any inner-tropical representative investigated. This includes the Sumatran Leafbird, the only recorded clutch of which was laid in an aviary in Germany. Three-egg clutches are known, and may even be regular, in northern parts of the ranges of Jerdon's, Golden-fronted and Orange-bellied Leafbirds, and have also been reported a few times for Blue-winged Leafbird but, again, only in the far northern part of that species' range.

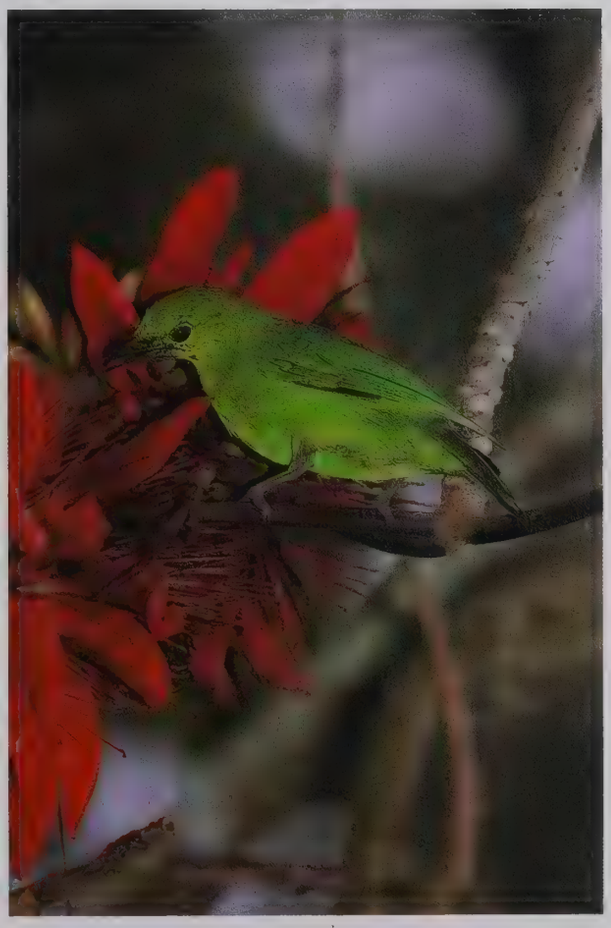
All known eggs of chloropseids are ovate in shape, longish to regular or, in the case of the Greater Green and Orange-bellied Leafbirds, broad. Those of the Blue-winged Leafbird in north-east India are creamy white to white, with pinkish, purplish-brown or black speckles and pencil markings over the broad cap or in a blurred zone around it. These markings are all black in Javan examples. Eggs of the related Jerdon's Leafbird are similar, with a sparing spread of speckles and pencillings of pinkish-brown to dark brown, or reddish, purplish and black, mainly over the broad end. The Golden-fronted Leafbird's eggs differ in being creamy to pinkish cream, with lavender and red-brown freckles and flecks, rather than pencil marks, all over to mainly over the broad end. Interestingly, two Sumatran Leafbird eggs were quite similar, cream with irregularly sized and shaped light red-brown flecks all over, but densely packed only over the broad pole. The pattern of the Orange-bellied Leafbird's eggs is also close to that of the Golden-fronted and Sumatran, but the speckling is said to be darker on average. A single Greater Green Leafbird egg, from north-east Sumatra, is creamy white, finely and densely speckled all over with pinkish-red to purplish-red, with larger flecks of the same colours over the broad end, and more generally scattered flecks of lilac-grey. Across the family, recorded egg size ranges from that of the Sumatran Leafbird, at 26 × 16 mm, down to that of Jerdon's Leafbird, at 23·1–19·3 × 15·8–14·3 mm, but eggs of some Orange-bellied Leafbirds of the nominate race have a width of up to 17·5 mm, and those of the Greater Green Leafbird can be at least 18·2 mm wide. These figures exclude the undescribed eggs of the Lesser Green and Blue-masked Leafbirds, which are presumed to lie at the small end of the scale.

The only data on incubation and fledging periods are, again, derived from observations of pairs in aviaries. These indicate that the Golden-fronted Leafbird incubates for 14 days, the Sumatran for 13–14 days, the Blue-winged for 13·5 days and the Orange-bellied Leafbird for 13 days. The fledging period of the Golden-fronted Leafbird is 15 days and that of the Orange-bellied Leafbird is 12 days, but fledging periods affected by diet in captivity may not, of course, exactly match those in the wild.

Movements

Orange-bellied Leafbirds of the Himalayan foothills migrate altitudinally, making post-breeding downslope shifts of 1000 m or more, to as far as plains level in Assam. At least those populations of this leafbird living towards the outer limit of the species' distribution, in south China, are liable to make similar movements. On the same Himalayan slopes, but at a lower extreme elevation and over shorter distances, marginal populations of the Golden-fronted Leafbird behave likewise.

The only other supposed long-distance movement, claimed by E. C. Stuart Baker in the early decades of the twentieth century, is of "irruptive" Blue-winged Leafbirds invading the hills of Assam from, it was presumed, Myanmar. Stuart Baker stated that many of these overwintered in Assam, and a few bred in certain years, separated by blocks of years with no reports at all. Stuart Baker's record seems to be the only one of this nature, and none of the recent ornithological literature dealing with the Indian Subcontinent makes mention of it.



Otherwise, leafbirds are thought to be sedentary. Even so, it may be supposed that regular flower-visitors disperse locally, and they may trap-line around scattered, traditional but intermittent sources of nectar (see Food and Feeding). These are the species

that, when not breeding, forage collectively, and apparently also travel in groups, as do, for example, trap-lining Asian Fairy-bluebirds (*Irena puella*).

Relationship with Man

All leafbirds are spectacular in appearance. As stated earlier (see Voice), most, and probably all, are also prodigious singers, incorporating much material into their songs by accurate mimicry well into adulthood. Although notoriously aggressive towards conspecifics and others in aviaries, when alone in a cage they are tamable and tractable, natural acrobatic behaviour converting quickly to simple trick routines. In addition, because of the fruit component of the diet, most or all of the species are relatively easy to maintain. It is no surprise, therefore, that leafbirds are traditionally favoured cagebirds. A scan of the more important western avicultural literature of the past 20 years revealed no fewer than 26 papers devoted exclusively to this group, and covering all except the two Philippine species, although with strong emphasis on the Golden-fronted and Orange-bellied Leafbirds. The extra-regional trade in wild-caught birds, moreover, must be small in proportion to that conducted within Asia itself. The Orange-bellied Leafbird is a firm favourite as a cagebird in, for example, Assam, and the Golden-fronted Leafbird far more widely so. The standing population of captives of these two alone must be vastly greater in Asia than the number found in the totality of western foreign-bird aviaries, including those of zoos.

In the field, the aggressiveness of leafbirds, together with the attraction of certain species to flowering crowns, makes these birds particularly easy to take in a cage-trap with a decoy raised into the canopy on a long pole. Such techniques are traditional and, as an outcome, many populations of the Golden-fronted Leafbird, in particular, have been depressed by overhunting for the pet trade. Comments on the decline in numbers around Calcutta, in India, for example, were being published well before the Second World War, and in 1936 Satya Churn Law described the Calcutta market trade in this species as "astonishingly huge".

Many leafbirds are essentially common forest-dwelling species, but their reliance on a disappearing habitat means that their populations are declining, along with their prospects of long-term survival. The ***Lesser Green Leafbird*** *is one such species, a denizen of South-east Asia's vanishing evergreen forests. Even though it occurs in secondary habitat, and at least marginally into the submontane zone where habitat loss is less severe, the sheer scale of recent forest clearance in the Sundaic region means this species must have suffered a drastic decline. It is listed as Near-threatened.*

[*Chloropsis cyanopogon*, Taman Negara, Malaysia. Photo: Ong Kiem Sian]

Damaging numbers of leafbirds are also captured in South-east Asia, including Thailand. During 26 months of weekly surveys of one major city market, the Bangkok "Sunday Market", in the late 1960s, McClure and S. Chaiyaphun conservatively estimated 4400 "aegithinids" on sale, apparently predominantly Golden-fronted Leafbirds. Over 900 individuals of this one species alone were logged in their 1968 survey.

Status and Conservation

Most leafbird species are still a fairly common sight in appropriate habitat, except in areas where their numbers have been reduced by sustained trapping (see Relationship with Man). Only the Blue-masked Leafbird is believed to be rare naturally, but dedicated fieldwork on its native Sumatran slopes may show even that to be untrue. It is currently listed as Near-threatened.

In various parts of their ranges, Blue-winged, Jerdon's, Golden-fronted and Orange-bellied Leafbirds extend into secondary vegetation, orchards and even wooded gardens, and probably most species exploit the mass fruiting of pioneer vegetation colonizing gaps made in tall forest. In certain circumstances, therefore, members of this family may actually benefit from the medium-term outcome of limited, selective disturbance of forest, including that by logging, except that, unfortunately, fruit sources such as lianas and the local canopy-fruiting fig community are often the targets of subsequent silvicultural "treatment".

At root, however, all leafbirds are forest-dependent. Even though, as all are canopy birds, none is vulnerable to the microclimate shock that logging of evergreen stands imposes on the shade-layer fauna, all lowland species have disappeared from huge parts of their former ranges within the last century or so, and particularly over recent decades, as a result of clearance of habitat. The Red Data Book listing of the Philippine Leafbird, believed to have been reduced to a handful of population pockets on Mindanao and perhaps still on Samar, but extinct on Cebu and probably also on Leyte, is due to this loss. This species is classified as Vulnerable. Two others are currently listed as Near-threatened: the Blue-masked Leafbird of Sumatra is mentioned at the start of this section; the Lesser Green Leafbird, is still more or less common, but it has disappeared from much of its former range as a result of substantial forest clearance. At a lower taxonomic level, some subspecies of other chloropseids, such as the Javan races of the Blue-winged and Greater Green Leafbirds, must now be in a considerably worse state.

Much depends on the capacity of these and other lowland leafbirds to sustain populations on slopeland. Throughout tropical Asia, this is where most of the forest habitat that has survived the current harvesting onslaught is becoming isolated and, indeed, where most of it occurs in parks and reserves.

Also for habitat reasons, and trapping notwithstanding, the chloropseid that is doing best overall has to be the mainly montane Orange-bellied Leafbird. Despite the fact that it is caught in large numbers for the cagebird trade, this species appears to be common and thriving in many parts of its relatively large range. Indeed, Hong Kong ornithologists believe that increasing numbers settling hill woodland of the territory constitute natural spread or, possibly, recolonization from nearby areas, a bold claim for any bird species in south China.

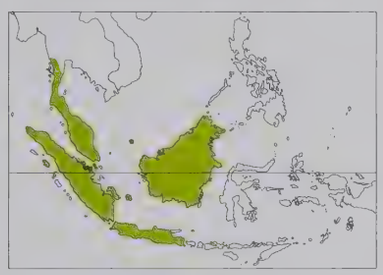
PLATE 27

inches 4
cm 10



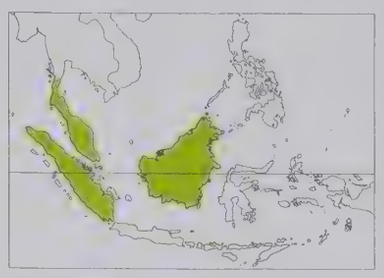
Genus *CHLOROPSIS* Jardine & Selby, 1827

1. Greater Green Leafbird

Chloropsis sonnerati

French: Verdin de Sonnerat **German**: Dickschnabel-Blattvogel **Spanish**: Verdín de Sonnerat
Other common names: Greater/Malachite-shouldered Leafbird

Taxonomy. *Chloropsis Sonnerati* Jardine and Selby, 1827, Java.
Named race *parvirostris*, from Nias I (off W Sumatra), merged with *zosterops*, as its bill characters fall within range of variation of mainland populations. Two subspecies recognized.
Subspecies and Distribution.
C. s. zosterops Vigors, 1830 – S Myanmar (C Tenasserim) and SW Thailand S to Sumatra and satellites, E to N Natuna group and Borneo.
C. s. sonnerati Jardine & Selby, 1827 – Java.



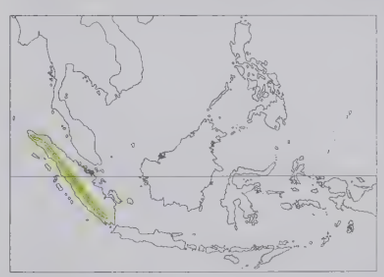
Descriptive notes. 18–21 cm; male 42·9–48·2 g, two females 38 g and 41·2 g (*zosterops*). Largest and heaviest leafbird, with relatively long, powerful, hook-nailed bill. Male nominate race has lores, face (enclosing part of eye) and chin to upper breast black (shape of bib varying individually), lustrous cobalt-blue flash along jaw from below angle of mouth; turquoise patch on lesser upperwing-coverts, straw-yellow outer webs of primaries P5–P8; rest of plumage rich, slightly glossy grass-green, a shade paler below; iris dark brown; bill blackish; feet slate-coloured with blue to greenish tinge. Female lacks black mask, has paler blue jawline flash, and bright yellow chin, throat and narrow eyering. Juvenile resembles female, but with yellow streak behind mouth, no jaw flash. Race *zosterops* differs from nominate only in being slightly less bright green, with wing-covert patch viridian-green rather than turquoise. Voice. Song a varied sequence of powerful, liquid, warbling phrases, e.g. "wit-chew", "wee-wu", "weet-weet", "wee-twit-twit", "chew-prrt-prrt-chew" and similar, interspersed with chattering, e.g. "wi-i, chaka-wiu, chi-wiu", and with much mimicry, including of Asian Fairy-bluebird (*Irena puella*) calls.
Habitat. Canopy and high edge of lowland evergreen forest and peatswamp-forest, well-grown secondary forest, also mature and well-regenerated tall back mangroves (now a rare habitat); occasionally also heavily wooded parkland and tree-shaded plantations, and visits fruit crops in isolated trees and shrubs of clearings. Sea-level to 900 m in N Malay Peninsula, and to 1100 m elsewhere, with some wandering into extreme base of lower montane forest.
Food and Feeding. Generalist; diet arthropods and fruits, also flower nectar. Animal prey gleaned from foliage, include large orthopterans (to size of locust), mantids, stick-insects (Phasmida) and caterpillars; chases flushed items. Fruits include canopy figs (*Ficus*) of many species, diameter up to 35 mm, also numerous smaller berries. Small fruits and small pieces of large fruit eaten directly; intermediate-sized, tough-coated items are pierced, and the contents then loosened and squeezed out by using the bill. Recorded at tubular flowers of an epiphytic gesneriad, punctured at base of its corolla for nectar, and at a *Loranthus* mistletoe, but flower-visiting not known to be regular. Forages alone or in pairs; may join mixed-species flocks of insectivores. At times, individual males defend limited sources of fruit (only), vigorously so against other leafbirds, including conspecifics.
Breeding. In N Borneo, males with large testes in mid-Jan, Mar, Jun and mid-Jul and females showing evidence of recent laying in Jun and mid-Oct; nest-building in early Jul and dependent fledglings in Apr and May in Malay Peninsula. Solitary breeder. Nest an open cup cradled between outer twigs of lateral branch, once 6 m up. No information on clutch size or incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Race *zosterops* still more or less common where habitat remains; small population persists on Singapore I (S Malay Peninsula), where, apart from tiny Bukit Timah Nature Reserve and remnant mangroves (latter not or no longer used by this species), all habitat has been secondary for a century. Nominate race, confined to Java, thought now to be scarce, its population fragmented into scattered pockets; no confirmation of any wild-living individuals in adjacent Bali.
Bibliography. Chasen (1924), Dunn (1974), Finsch (1905), Inskipp *et al.* (1996), Jeyarajasingam & Pearson (1999), Lambert (1989b), Lekagul & Round (1991), MacKinnon & Phillipps (1993), van Marle & Voous (1988), McClure (1966, 1967), Medway & Wells (1976), Mees (1986), Meyer de Schauensee & Ripley (1940), Nash & Nash (1985), Riley (1938), Robson (2000), Sheldon *et al.* (2001), Smythies (1986, 1999), Strange (2002), Stuart Baker (1922–1930), Thompson (1966), Wells (1985c, 2005).

2. Lesser Green Leafbird

Chloropsis cyanopogon

French: Verdin barbe-bleue **German**: Blaubart-Blattvogel **Spanish**: Verdín Gorgiazul
Other common names: Blue-whiskered Leafbird

Taxonomy. *Phyllornis cyanopogon* Temminck, 1830, Palembang, Sumatra.
Two subspecies recognized.
Subspecies and Distribution.
C. c. septentrionalis Robinson & Kloss, 1919 – extreme S Myanmar (S Tenasserim), SW Thailand and N Malay Peninsula.
C. c. cyanopogon (Temminck, 1830) – S Malay Peninsula, Sumatra, and Borneo (including Banggi I, off N coast).



Descriptive notes. 15–16·2 cm; male 20·3–22·8 g, female 18·5–20·5 g (*cyanopogon*). Male nominate race has a trace of brassy yellow on forehead, black facial mask (enclosing part of eye) and chin to uppermost breast, cobalt-blue flash along jawline; viridian-green patch on lesser upperwing-coverts; rest of plumage slightly glossy grass-green, a shade paler below, and brightest narrowly around edge of bib; iris dark brown; bill blackish, or with slaty lower mandible; feet grey to lead-blue. Distinguished from *C. sonnerati* by smaller size, lighter build, yellow on forehead, black of mask usually extending less far down breast, no yellow on primaries. Female lacks mask, has jawline flash paler. Juvenile is female-like, but lacks jawline flash, has yellow eyering and throat. Race *septentrionalis* is on average smaller than nominate, with stronger brassy wash over anterior cap of both sexes, male has narrow but clear yellow border to black bib. Voice. Song a loud, varied sequence of rich warbling phrases including deep, mellow notes and frequent doubled elements.
Habitat. Canopy and high edge of lowland evergreen forest, including peatswamp-forest, mature and regenerating, well-grown secondary forest, also fruiting trees and shrubs of clearings, and high shade cover of plantations; exceptionally, strand woodland on coasts. Sea-level to 700 m on submontane slopes; a few records to 1100 m (i.e. into base of montane forest) in Peninsular Malaysia.
Food and Feeding. Generalist; diet arthropods, fruits, occasionally flower nectar. Arthropods gleaned from canopy foliage, include caterpillars, beetles (Coleoptera), flies (Diptera); chases flushed items. Fruits taken include many types of fig (*Ficus*), to maximum width of 27 mm; among diverse berries, *Eugenia*, *Loranthus*, *Pipturus*, *Callicarpa*, *Muntingia*, *Poikilospermum* species identified. Small fruit items eaten directly; intermediate-sized, tough-coated items are pierced, and the contents then loosened and squeezed out by using the bill. Flower-visiting unusual, but recorded at eucalypt (*Eucalyptus*) blossoms, and seen to obtain nectar of an epiphytic gesneriad by puncturing the tubular flowers at base of corolla. Forages alone or as a pair; often joins mixed-species flocks of other insectivores.
Breeding. Adults with enlarged gonads during late Feb–Aug; an instance of nest-building in late Jun, and nestlings and recent fledglings in Apr and Jun. Solitary breeder. Nest not described, built in outer part of lateral branch high above ground, once 12 m up. Clutch size and incubation and fledging periods not recorded.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. More or less common where habitat remains, but has disappeared from substantial areas of range as a result of forest clearance. Occurs in several protected areas, including Khao Para-Bang Khram Wildlife Sanctuary (Thailand), Danum Valley Conservation Area (Borneo) and Way Kambas National Park (Sumatra).
Bibliography. Collar *et al.* (2001), Danielsen & Heegaard (1995), Dunn (1974), Inskipp *et al.* (1996), Jeyarajasingam & Pearson (1999), Lekagul & Round (1991), MacKinnon & Phillipps (1993), van Marle & Voous (1988), McClure (1966, 1967), Medway & Wells (1976), Meyer de Schauensee & Ripley (1940), Nash & Nash (1985), Riley (1938), Robson (2000), Smythies (1986, 1999), Stattersfield & Capper (2000), Strange (2002), Thompson (1966), Wells (1985c, 2005).

3. Blue-masked Leafbird

Chloropsis venusta

French: Verdin à front bleu **German**: Blaustirn-Blattvogel **Spanish**: Verdín Frentiazul
Other common names: Masked Leafbird, Sumatran Leafbird(!)

Taxonomy. *Phyllornis venusta* Bonaparte, 1850, Sumatra.
Monotypic.
Distribution. Upland Sumatra, from Aceh S along Barisan Range to Lampung.

Descriptive notes. 14 cm. The smallest leafbird. Adult male has anterior cap violet-blue, lores and anterior face deep indigo, supraloral fringe and ear-coverts aquamarine-blue, and jawline flash intense violet-blue; rest of head and upperparts grass-green, with leading edge of lesser wing-coverts viridian, edge of carpus bright cobalt-blue, outer half of tail blue; chin and throat deep brown to blackish-brown, breast orange edged yellow, remaining underparts emerald-green; iris red-brown; bill black; feet purplish-brown, yellower on soles. Adult female has forehead, lores, ear-coverts, chin and throat bright blue, outer half of tail dull blue; otherwise grass-green, brighter below. Juvenile undescribed. Voice. Undescribed.
Habitat. Canopy of lowland (submontane) evergreen and lower montane forests, mature and well regenerated; also in forest-edge vegetation around clearings. At 600–1500 m; principally within lower montane zone, c. 1000 m and above.
Food and Feeding. Stomach contents fruit seeds, insects and arthropod eggs. Feeding method undescribed. Regular social unit said to be a pair, but reported a few times in parties of up to six individuals.
Breeding. No information.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Sumatra and Peninsular Malaysia EBA. Information on population level deficient; believed generally uncommon to sparse. Continuing loss of forest on lower slopes is restricting this and other species to higher elevations.

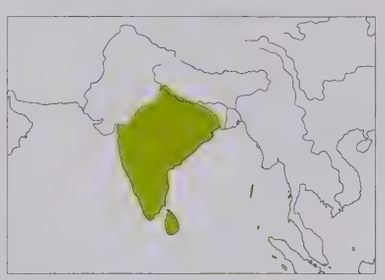
Yellow-throated Leafbird (*Chloropsis palawanensis*); 8. Philippine Leafbird (*Chloropsis flavipennis*); 9. Golden-fronted Leafbird (*Chloropsis aurifrons*); 10. Sumatran Leafbird (*Chloropsis media*); 11. Orange-bellied Leafbird (*Chloropsis hardwickii*).

4. Blue-winged Leafbird

Chloropsis cochinchinensis

French: Verdin à tête jaune **German**: Blauflügel-Blattvogel **Spanish**: Verdín Aliazul
Other common names: Green Leafbird, Golden-headed/Yellow-headed Leafbird, Gold-mantled Chloropsis

Taxonomy. *Turdus Cochinchinensis* J. F. Gmelin, 1789, Cochinchina; error = Java.
Probably forms a superspecies with *C. jerdoni*, *C. kinabaluensis* and *C. palawanensis*; until recently was regarded as conspecific with first two. The name *nigricollis*, long used for the Javan (nominate) race, has no designated type or type locality, and therefore no formal taxonomic standing. Described races *icterocephala* (from Sumatra), *billitonis* (Belitung) and *natunensis* (Natuna Is) considered better merged with *moluccensis*. Seven subspecies recognized.
Subspecies and Distribution.
C. c. chlorocephala (Walden, 1871) – extreme E Bangladesh and NE India (Assam) E to Myanmar and W Thailand.
C. c. kinneari B. P. Hall & Deignan, 1956 – S China (S Yunnan), N Indochina and NE Thailand.
C. c. auropectus Wells *et al.*, 2003 – SE Thailand and S Indochina.
C. c. serithai Deignan, 1946 – N Malay Peninsula.
C. c. moluccensis (J. E. Gray, 1831) – S Malay Peninsula, Sumatra and satellites and N Natuna Is.
C. c. viridinucha (Sharpe, 1877) – Borneo (except far N).
C. c. cochinchinensis (J. F. Gmelin, 1789) – Java.



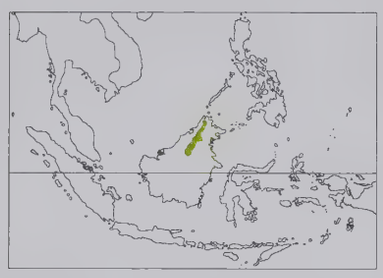
Descriptive notes. 15·8–17·7 cm; male 20–28·5 g, female 19–25 g (*moluccensis*). Male nominate race has black mask from lores to throat, enclosing short, intensely violet-blue jawline flash and partly enclosing eye, shape of bib individually variable; upperparts grass-green, bronzy-tinted over cap and nape; lesser wing-coverts shining blue; outer webs (narrowly edged green) of secondary coverts, tertials and secondaries and whole carpus, alula, primary coverts and primaries bright aquamarine to turquoise; much blue on tail; below, bib surrounded by clear yellow, this broadening into large apricot-yellow patch on breast; remaining underparts bright green, slightly lighter than upperparts; iris brown to red-brown; bill black, or with slaty lower mandible; feet greenish-grey. Female lacks mask, has rather less intense blue on wing and tail, turquoise-green chin and throat merging with blue of jawline flash, and brassy-tinted head, but no true yellow. Juvenile is like female, but has greener throat and no jaw flash. Races vary mainly in details of coloration and pattern of male head and breast, and tone of blue colours: *viridinucha* is like nominate, but yellow of mask border runs around eye, forward over lores, and infills anterior cap, blue areas of wing are richer, cobalt-blue, blue on tail brighter, yellow border of bib of even width (no accentuated breast patch) and backed by bright viridian, remaining underparts viridian-tinted green; *moluccensis* resembles previous, except yellow on cap continues back to nape, where bronzy-washed, yellow bib border narrows onto breast, viridian surround absent, remaining underparts lime-green; *serithai* differs from last in having yellow of cap confined to forehead and sides, pea-green patch on central forecrown, yellow bib border of even width; *auropectus* is like nominate, but has pea-green forecrown patch, and yellow runs around eye, forward above lores and onto forehead; *chlorocephala* resembles previous, except breast patch behind bib less bright yellow and less well demarcated from remaining underparts; *kinneari* is similar to last, but greens slightly darker, bib surround narrower, breast patch duller and even less well demarcated. Voice. Song of various musical, liquid notes, e.g. as "pli-pli-chu-chu", "chi-chi-pli-i" and similar; in NE Indian Subcontinent (race *chlorocephala*) described as "very sweet". In Malay Peninsula, partners communicate with 2-note "kwip-kweep". Elsewhere, a "scrit-chew", first note scratchy, second strongly downslurred, and an upslurred "sfweet" described as sweet and wheezy; also, high-pitched "chi-chi-chi" and "chi'ii", and slightly rattling "pridit".
Habitat. Canopy and edge of evergreen and semi-evergreen forests, including (at least in Sunda region) peatswamp-forest, mature and disturbed; also well-grown secondary forest and nearby mixed orchards, emerging to visit isolated, sometimes low-stature fruit sources in clearings and by tracks and waterways through forest. At plains level and on slopes to 1250 m in Malay Peninsula, to 1400 m in N Vietnam and W Myanmar, to 1500 m in Java, and to 1800 m in India (including in E Himalayan foothills). These upper limits imply some penetration of montane forest, typically in disturbed or secondary vegetation. In India, said to range down to just above plains level, but common at low elevations where humid forest habitat available more widely. The commonest leafbird species of humid edge and secondary growth, which, at least in Sunda region, and independent of altitude, appear to be its core habitat.
Food and Feeding. Generalist; diet arthropods, also fruits, probably also nectar. Arthropods, gleaned from foliage, include orthopterans up to size of large locust and equivalent-sized caterpillars. Fruit part of diet includes figs (*Ficus*) 4–27 mm in diameter, but in Peninsular Malaysia of many fewer species than are visited by *C. sonnerati* and *C. cyanopogon*; also numerous smallish berries (those of *Fagraea*, *Melastoma*, *Callicarpa*, *Eugenia* and introduced *Muntingia calabra* identified in Malaysia). Small fruit items eaten directly; medium-sized, tough-coated items are pierced, and the contents then loosened and squeezed out by using the bill. Visits to flowers of a gesneriad and Myrtaceae in Malaysia assumed to have been for nectar; in N part of SE Asia a frequent visitor to shrubs and trees in flower, including nectar-yielding *Bombax*. Forages alone, paired or in parties, including those of mixed species.
Breeding. Breeds during Apr–Jul in NE Indian Subcontinent; dependent fledglings in May, Jun and Jul in Malay Peninsula, and active nests in Feb, Apr and Jul in Java. Open hammock-type nest of tendrils, dry grasses, "rootlets" and the odd tree leaf, heavily camouflaged with bryophytes and lichens, felted externally with cobweb, suspended from rim 6–10 m up between twigs or fork prongs towards outer end of lateral branch. Clutch 2 eggs, occasionally 3 in N outer tropics; incubation period in captivity 13·5 days; no information on fledging period.
Movements. Probably resident. Claimed irruptions in Assam hills (NE India), with many wintering and a few subsequently nesting, then several years of absence, not regarded as confirmed. No other movements known.
Status and Conservation. Not globally threatened. Relatively common throughout most of range; common in much of SE Asia, including in several protected areas, but scarce in Singapore. Now rather rare in Java.
Bibliography. Ali (1996), Ali & Ripley (1996), Brockelman (1982), David-Beaulieu (1944), Deignan (1945), Duckworth *et al.* (1999), Dunn (1974), Eames & Ericson (1996), Grewal *et al.* (2002), Grimmett *et al.* (1998), Hardy (2003), Holmes (1996), Jeyarajasingam & Pearson (1999), Lekagul & Round (1991), MacKinnon & Phillipps (1993, 2000), van Marle & Voous (1988), McClure (1966, 1967), Medway & Wells (1976), Meyer de Schauensee & Ripley (1940), Rasmussen & Anderton (2005), Riley (1938), Ripley (1982), Robinson (1927), Robson (2000), Smith (1943), Smythies (1986, 1999), Stepanyan (1995), Strange (2002), Stresemann & Heinrich (1939), Stuart Baker (1922–1930, 1932), Wells (2005).

5. Jerdon's Leafbird

Chloropsis jerdoni

French: Verdin de Jerdon **German**: Jerdonblattvogel **Spanish**: Verdín de Jerdon
Other common names: Indian Leafbird, Jerdon's Chloropsis

Taxonomy. *Phyllornis jerdoni* Blyth, 1844, central India.
Probably forms a superspecies with *C. cochinchinensis*, *C. kinabaluensis* and *C. palawanensis*; was for long regarded as a race of first of those, but differs in bill morphology and plumage details. Wing length in N (male 92–93 mm, two females 86 mm and 88 mm) larger than in S (male down to 85 mm in Sri Lanka), but differences considered insufficient to warrant naming of geographical races. Monotypic.
Distribution. India S from S Gujarat (Gulf of Cambay), C Uttar Pradesh, Bihar and West Bengal, and Sri Lanka.



Descriptive notes. 16·7–18·4 cm. Male has black mask from lores back to eye and entire throat, enclosing large, long, intensely violet-blue jawline flash; rim around part of eye free of mask clear yellow, and yellow continues narrowly round margin of bib; cap and broad collar around bib brassy greenish-yellow; plumage otherwise bright grass-green, lighter below, relieved only by glossy turquoise lesser upperwing-coverts and straw-yellow distal outer webs of emarginated primaries; iris brown; bill black, or with grey base of lower mandible; feet slaty grey. Distinguished from *C. cochinchinensis* mainly by lack of blue on flight-feathers and tail, longer jawline flash. Female is like male but lacks mask, has anterior cap olive-yellow and meeting viridian-tinged green at hindcrown level, entire eyelid rim yellow, clean-cut bib turquoise (only slightly duller than jawline flash) and with same yellow border as male; otherwise as male. Juvenile is like female, but cap green (rather than yellowish), bib indistinct, no jawline flash. Voice. Song with random, varied combinations of loud, clear whistles, buzzing notes and rich, sharp notes, said to be similar to that of *C. aurifrons* but slightly deeper, richer and slower; includes much mimicry, especially of drongos (*Dicrurus*), also of Oriental Magpie-robin (*Copsychus saularis*), jungle babblers (*Turdoides*), tailorbirds (*Orthotomus*) and Shikra (*Accipiter badius*). Calls include a jarring rattle, and non-breeders in small parties communicate with a sharp "click".
Habitat. Open forest, secondary growth, orchards, wooded gardens, coconut gardens, and wooded edges of roads, rivers, paddyland, and coffee, pepper vine etc. plantations; including deciduous vegetation. Favours relatively dry conditions, decreasing in numbers with rising general humidity. At plains level and on slopes to not above 1200 m, usually lower. Some habitat and range overlap with *C. aurifrons*, but prefers drier, more open sites.
Food and Feeding. Generalist; diet arthropods and fruit, also nectar. Arthropods include caterpillars, crickets (Tettigoniidae), ants (Hymenoptera) and mantids, gleaned acrobatically in canopy foliage. Fruit part of diet includes figs (*Ficus*) and various berries. Also a regular flower-visitor, evidently seeking nectar; recorded as visiting *Helicteres*, *Loranthus*, *Salmalia*, *Erythrina*, *Cocos* and others. Forages singly or as pair, and joins mixed-species hunting parties. Individuals may defend a nectar source pugnaciously, but at other times apparent non-breeders attend flower crops in parties, and trap-line socially between sources; parties have also been recorded as eating the ripe flower buds of *Anthocephalus cadamba*.
Breeding. Some breeding occurs in all months, but main season in N of range Mar–Sept and in S (including Sri Lanka) Nov–May. Variable-depth open cup-nest, compactly woven, materials include dry grass and soft fibres, with leaf and bark fragments added externally, and felted with cobweb, some silk running through the structure on to its support, with rudimentary lining; suspended at rim from prongs of thin outer fork at canopy level, 5–10 m above ground, typically in shade of overhanging foliage. Clutch 2 eggs, rarely 3 (but perhaps more regularly so in N of range); no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common; apparently more common on slopes than at plains level. Many populations are held below potential density by effects of trapping for the wildlife trade.
Bibliography. Aitken (1886), Ali (1969, 1996), Ali & Ripley (1996), Bhunya & Mohanty (1987), Dunn (1974), Dutt (1932), Grewal *et al.* (2002), Grimmett & Inskipp (2003), Grimmett *et al.* (1998), Harrison (1999), Henry (1998a), Kazmierczak (2000), Lamsfuss (1998), Legge (1983), Mahabal & Lamba (1987), Majumdar *et al.* (1992), Mason & Lefroy (1912), Phillips (1978), Rasmussen & Anderton (2005), Ripley (1982), Saha & Dasgupta (1992), Stuart Baker (1922–1930, 1932), Wait (1925), Whistler & Kinnear (1933), de Zylva (1984).

6. Bornean Leafbird

Chloropsis kinabaluensis

French: Verdin de Bornéo **German**: Kinabalublattvogel **Spanish**: Verdín de Borneo

Taxonomy. *Chloropsis kinabaluensis* Sharpe, 1887, Mount Kinabalu, Sabah, Borneo.
Specific name sometimes given as *flavocincta*, but original describer subsequently gave precedence to present name. Probably forms a superspecies with *C. cochinchinensis*, *C. jerdoni* and *C. palawanensis*; was for long regarded as a race of first of those, but differs in bill morphology and plumage, exhibits lesser degree of sexual size dimorphism (mean 3% versus 8%), and ranges approach or meet each other without evidence of intergradation. Monotypic.
Distribution. N Borneo, from Mt Kinabalu S along the spinal mountains to Mt Dulit and the Usun Apau Plateau and E to Kayan Mentarang.
Descriptive notes. 17·5–18·4 cm. Male has full black mask from lores and eye to throat, enclosing large blue jawline flash, and with entire yellow border that broadens on breast and also infills anterior cap to forecrown level; rest of cap and upperparts bright lime-green, bronzy-tinged on hindcrown; lesser upperwing-coverts shining blue, outer webs of secondary coverts (narrowly edged green), tertials and secondaries and whole of carpus, alula, primary coverts and primaries bright aquamarine; much blue on tail; underparts below breast green with yellowish tinge; iris dark brown;

bill black; feet greenish-grey. Distinguished from *C. cochinchinensis* (of Bornean race *viridinucha*) mainly by yellower-tinted plumage, much larger and bluer jawline flash, entire yellow border of bib that broadens on breast, blue on wings bright aquamarine (rather than rich cobalt), larger size (male wing 95–100 mm; *viridinucha* 83–87 mm), proportionately heavier, more strongly notched and prominently nail-tipped bill. Female differs from male in having well-demarcated bright viridian (rather than yellow) mask surround, rest of cap emerald-green without bronzy tinting, no jawline flash. Juvenile lacks mask, but other details unknown. Voice. Not described.

Habitat. Canopy and high edge of lower and upper montane forests, mature and well regenerated, from 2200 m down to the montane ecotone; in Sabah, N of the range of lowland *C. cochinchinensis*, disperses below it into evergreen forest of upper submontane slope. At extreme N limit of occurrence, on Mt Kinabalu itself, recorded down to 550 m.

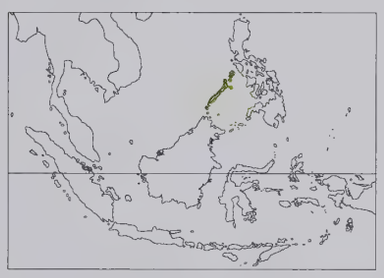
Food and Feeding. Few data. Recorded as taking berries and dragonflies (Odonata). Forages alone, in pairs and occasionally in small parties; joins mixed-species foraging flocks.

Breeding. An instance of nest-building in mid-Nov; an oviduct egg of a "blue-winged leafbird" from the Bario Plateau (Sarawak), dated late Nov, probably refers to this species on basis of altitude. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common throughout its small range.

Bibliography. van Balen (1997), Davison (1992), MacKinnon & Phillipps (1993), Sheldon *et al.* (2001), Smythies (1999), Strange (2002), Wells, Dickinson & Dekker (2003b), Wells, Hails & Hails (1978), Wilkinson, Dutson & Sheldon (1991), Wong & Phillipps (1996).



7. Yellow-throated Leafbird

Chloropsis palawanensis

French: Verdin de Palawan **German**: Palawanblattvogel **Spanish**: Verdín de Palawan
Other common names: Palawan Leafbird

Taxonomy. *Phyllornis palawanensis* Sharpe, 1876, Palawan, Philippines.
Probably forms a superspecies with *C. cochinchinensis*, *C. jerdoni* and *C. kinabaluensis*. Monotypic.

Distribution. W Philippines: Calamian Group (Calauit, Busuanga and Culion) and Palawan (including its satellites Dumaran and Balabac).

Descriptive notes. 15·8–17·2 cm. Male has lores and narrow eyelid rim bright turquoise, jawline flash violet-blue; rest of anterior face yellowish, shading to yellowish-green on ear-coverts; cap and upperparts yellow-tinged grass-green, leading edge of lesser wing-coverts, outer median coverts and entire carpus rich blue; alula, primary coverts and (apart from fine edging) outer webs of outer secondaries and primaries aquamarine, brightening to cobalt-blue on primaries P9 and P10; tail dull blue, central feather pair washed green; chin to lower throat chrome-yellow, underparts green, brighter and lighter than dorsum; iris brown; bill black, lateral base of lower mandible bright turquoise; feet grey. Female is as male, but with less blue on lesser wing-coverts. Juvenile undescribed; an adult-type plumage but without violet-blue jaw flash remains to be identified. Voice. A warbled disyllable, "zo-o", in isolation or repeated after short pause; also deliberate "twick err treet", similar to call of *C. flavipennis* but richer and slower, repeated at 5-second intervals.

Habitat. Canopy and edge of lowland evergreen forest; also visits secondary growth.

Food and Feeding. Diet unspecified, but fruit remains and seeds reported in stomach contents. Forages often alone; also joins mixed-species flocks, especially of bulbuls (Pycnonotidae).

Breeding. No information.

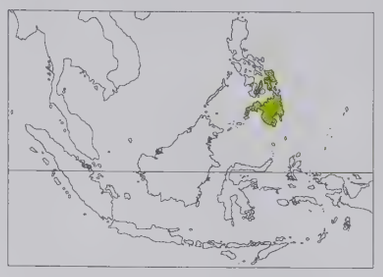
Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Palawan EBA. Not well known. Apparently still fairly common where suitable habitat persists. Occurs in St Paul Subterranean River National Park, on main island of Palawan.

Bibliography. Delacour & Mayr (1946), Dickinson *et al.* (1991), Dupond (1942), Inskipp *et al.* (1996), Kennedy *et al.* (2000), duPont (1971), Stattersfield *et al.* (1998).

8. Philippine Leafbird

Chloropsis flavipennis



French: Verdin à ailes jaunes **German**: Philippinenblattvogel **Spanish**: Verdín Filipino
Other common names: Yellow-billed/Yellow-quilled Leafbird

Taxonomy. *Phyllornis flavipennis* Tweeddale, 1878, Cebu, Philippines.
Relationships uncertain; its yellow flight-feather edging most closely resembles that of *C. jerdoni*. Birds from NE Mindanao, described as race *mindanensis*, considered inseparable from those in rest of range. Monotypic.

Distribution. C & S Philippines: Samar, Leyte, Cebu and Mindanao.

Descriptive notes. 18·8–19 cm. Has eyelid rim pale cream-yellow, lores the same but with bright green tipping; rest of upperside, to tail, viridian-tinted grass-green, except for brilliant green edging on outer webs of tail, tertials and secondaries, and creamy-yellow carpus edge, outer webs of alula and distal outer webs of emarginated primaries; chin and upper throat pale cream-yellow, merging below into bright yellowish-green, then pea-green; iris dark brown; bill dark horn-coloured, tip paler; feet olive-grey. Sexes alike. Juvenile undescribed. Voice. No song described. Calls include loud, repeated, disyllabic whistle, "chick weeeeep", notes well spaced; also a 3-note "chick-ur-treet".

Habitat. Canopy of lowland evergreen forest, mature and regenerating after disturbance, including habitats described as degraded and secondary; also forest-edge vegetation. Plains level and

slopes, from 100 m to at least 970 m, i.e. within limits of lowland dipterocarp forest; claimed extensions to 1270 m imply a shift into the base of lower montane forest, but that has never been corroborated.

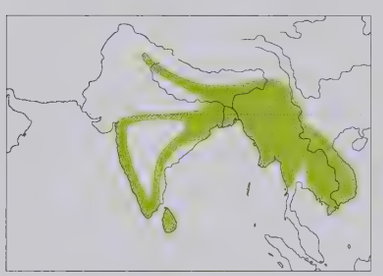
Food and Feeding. No information.

Breeding. Recorded in Jun and Aug, and adults with enlarged gonads in Apr and May. No other information.

Movements. Resident.

Status and Conservation. VULNERABLE. Restricted-range species: present in Cebu EBA (now almost certainly extinct) and Mindanao and the Eastern Visayas EBA. Conventionally classed as rare to very rare everywhere; for Mindanao this rating has recently been revised to "uncommon but secretive", but only one record from W peninsula of the island. Threatened throughout its range by advanced levels of habitat loss; this more or less complete on Cebu, where the species has not been reported since 1920 and is assumed to be extinct; continued existence on Samar and Leyte must also be doubted, with no records from either in more than three decades. It is probably no longer possible to define this species' core habitat, but ecological factors operating to limit real abundance may include the squeezing of populations on to major slopes; for many lowland-forest birds of the region these are reckoned to be of marginal quality, setting the stage for local extinction ahead of final forest clearances.

Bibliography. Anon. (1997b), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Collar, Mallari & Tabaranza (1999), Delacour & Mayr (1946), Dickinson *et al.* (1991), Inskipp *et al.* (1996), Kennedy *et al.* (2000), McGregor (1909–1910), duPont (1971), Ripley & Rabor (1968), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).



9. Golden-fronted Leafbird

Chloropsis aurifrons

French: Verdin à front d'or **German**: Goldstirn-Blattvogel **Spanish**: Verdín Frentidorado
Other common names: Gold-fronted Chloropsis

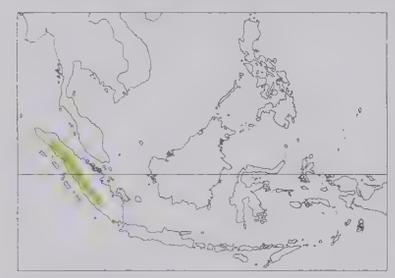
Taxonomy. *Phyllornis aurifrons* Temminck, 1829, Cachar, Assam, north-east India.
Forms a superspecies with *C. media* and was for long considered conspecific, but differs in several respects, including in development of mask. Six subspecies recognized.

Subspecies and Distribution.
C. a. aurifrons (Temminck, 1829) – NE Indian Subcontinent (E in Himalayan foothills from Himachal Pradesh, S to Orissa) and N, W & C Myanmar.
C. a. frontalis (Pelzeln, 1856) – W & E India (S from S Gujarat and the Satpura Range and, in E, from C Orissa).
C. a. insularis Whistler & Kinnear, 1932 – far SW India and Sri Lanka.
C. a. pridii Deignan, 1946 – S China (SW Yunnan), E & S Myanmar, NW & W Thailand and N & C Laos.
C. a. inornata Kloss, 1918 – EC & E Thailand, S Laos and C Vietnam.
C. a. incompta Deignan, 1948 – SW & SE Thailand, Cambodia and S Vietnam.

Descriptive notes. 17–19 cm. Male nominate race has orange forehead and forecrown; black mask extending from lores and eye to lower throat, within which entire chin, upper throat and malar region violet-blue; broad and prominent yellow band around lower part of bib; turquoise-blue lesser upperwing-coverts; all other plumage bright grass-green; iris dark brown; bill black; feet greenish-slate. Female differs from male only in having rather less blue on lesser wing-coverts, and in slightly smaller size; orange of forecrown tends to be somewhat duller. Juvenile is all green, except for yellow eyelid rim. Races vary mostly in extent of violet-blue within mask and of yellow bordering bib: *pridii* differs from nominate in having narrower yellow band around bib; *inornata* resembles previous, but has less orange on cap (extends back only to about mid-eye level), only a hint of yellow around bib; *incompta* is like nominate, but no yellow around bib; *frontalis* has long, intensely violet jawline flash but fully black chin and throat, orange on forehead only to mid-eye level, no yellow band around bib; *insularis* is separated from last mainly by size, male wing 91–93 mm (as opposed to 100 mm). Voice. Song, mostly from outer end of high branch at or just below canopy summit, a high-pitched, faltering but sweet, whistling twitter with warbled, scratchy and many repeated notes, e.g. "twitter, chirp, twit, twitter, twitter, tip, weety weety" or "vi-tu, tieu, tieu, tieu, tieu, vi-tchit", or "tswee-tswee-cheep-cheep", with much added mimicry (some songs virtually all mimicry), regularly of drongo (*Dicrurus*) sounds ("swích-chich-chich-wéé"); other models reported include bulbuls (Pycnonotidae), tailorbirds (*Orthotomus*), Oriental Magpie-robin (*Copsychus saularis*), ioras (*Aegithina*), shrikes (Laniidae), White-throated Kingfisher (*Halcyon smyrnensis*) and Crested Serpent-eagle (*Spilornis cheela*), also migrants, vocalizations of which continue to be used after their departure. Shorter contact calls, upward-inflected or downward-inflected, include "chup-chaw", "chi-wit, chi-wit", a sweet "zi-zi", "kaa-chip" like that of Streaked Spiderhunter (*Arachnothera magna*), harsh metallic "tzit" and "brnt-tzit", and voluble, whistling rattle; parties tend to be noisy while feeding.

Habitat. Canopy of deciduous forest to relatively open semi-evergreen to fully evergreen broadleaf forests, forest edge, secondary growth (including bamboo forest), tree plantations, wooded stands in coffee and tea estates, and wooded gardens. Plains level to c. 1200 m in N & E of range and exceptionally to 1800 m in S (Sri Lanka), but typically lower. In India, avoids the dry conditions favoured or tolerated by sympatric *C. jerdoni*.

Food and Feeding. Generalist; diet arthropods, fruits and nectar. Loners, pairs or small parties forage for arthropods in canopy foliage, often acrobatically on thin outer twigs; pursues flushed items, also takes winged termites (Isoptera), etc.; some flower-visiting is also for purpose of seeking insects. Fruits include figs (*Ficus*) and berries; small fruit items eaten directly, but medium-sized, tough-coated items are pierced, and the contents then loosened and squeezed out by using the bill. Nectar seems to be important in diet, and sources are at times defended individually; at other times parties of 4–12 or more trap-line between flowering crowns, epiphytic clumps etc., the commoner named sources being *Bombax*, *Erythrina*, *Butea*, *Salmalia*, *Woodfordia*, *Firmiana* and, especially, species of *Loranthus* mistletoe. Nectar reached for in tubular corollas,



often by hanging with head downwards, occasionally while hovering. Nectar of bananas (ordinarily reachable only with a long-protruding tongue) also taken, by puncturing base of tubular corolla.
Breeding. Through Indian Subcontinent overall some breeding occurs in all months, but with regional variation, thus in Feb–Aug (peak Jun/Jul) in S India and Sri Lanka; seasonality in SE Asia little known, probably Feb–Jul. Nest built by both pair-members, one site-guarding while the other forages for materials, an open cup of fine twigs, bryophytes, tendrils, grass, bark fibre, bamboo leaves and always some cobweb, sparsely lined with grass, secured hammock-like 9–12 m up between thin prongs of outer fork. Clutch 2 eggs, less usually 3 (but 3 eggs said to be the norm in Thailand); in captivity, incubation period 14 days and fledging period 15 days.
Movements. Mainly resident; slope-living populations in Himalayan foothills said to perform short-range vertical migrations.
Status and Conservation. Not globally threatened. Common to fairly common throughout most of range. Trade in this species, however, is heavy, and many of its populations are depressed by trapping for the cagebird market. Occurs in several national parks across its range, e.g. Royal Chitwan (Nepal), Corbett and Mudumalai (India), Doi Inthanon (Thailand) and Nam Bai Cat Tien (Vietnam).

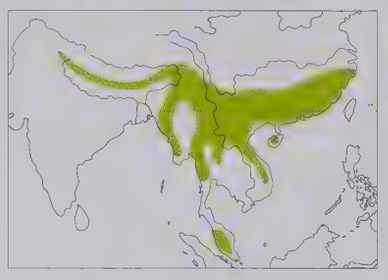
10. Sumatran Leafbird

Chloropsis media

French: Verdin de Sumatra **German**: Sumatra-Goldstirnblattvogel **Spanish**: Verdín de Sumatra

Taxonomy. *Phyllornis media* Bonaparte, 1850, Sumatra.
Forms a superspecies with *C. aurifrons* and was for long considered conspecific, but differs sufficiently, including in development of mask, to warrant species rank. Monotypic.
Distribution. Upland Sumatra, from Aceh S through Barisan Range to Selatan.



Descriptive notes. 17·7–18·8 cm; one female 40 g. Male has anterior cap back to mid-eye level clear yellow; mask from lores and eye to lower throat black, enclosing long, unusually narrow, intensely violet jawline flash; lesser wing-coverts out to carpal joint shining electric blue; plumage otherwise grass-green, lighter and brighter below; iris dark brown; bill black; feet dark grey to blackish. Female lacks black mask, has entire eyelid rim yellow, jawline flash turquoise, rather than violet, and blue on wing less prominent. Juvenile is all green, apart from yellow eyelid rim. Voice. Song of paired male in captivity loud and richly melodic; voice not otherwise described.
Habitat. Middle stratum and canopy of lowland evergreen forest, mature and regenerating, and secondary forest, plantations and village orchards; also visits trees standing out from edge of forest. Submontane slope at 600–1000 m; has not been demonstrated to enter montane forest, and core habitat still in doubt.
Food and Feeding. Little known. Probably generalist. Attracted to canopy-level crops of ripe figs (*Ficus*), but nothing known of other aspects of diet.
Breeding. In the wild, fledglings attended by adults in Jul. In captivity, one clutch of 2 eggs, incubation period 13–14 days. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Only recently split as separate species, and conservation status requires reassessment; in view of the fact that it is often treated as a race of the more widespread and generally common *C. aurifrons*, its conservation status has been largely ignored. Poorly known species. Common in W Sumatra in early 20th century; present-day status uncertain. Recorded in the recent European cagebird trade.
Bibliography. Chasen & Hoogerwerf (1941), Holmes (1996), Kloss (1931), Kraus (1986), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Meyer de Schauensee & Ripley (1940), Robinson & Kloss (1918, 1924).

11. Orange-bellied Leafbird

Chloropsis hardwickii

French: Verdin de Hardwicke **German**: Orangebauch-Blattvogel **Spanish**: Verdín de Hardwicke
Other common names: Hardwicke's Leafbird, Orange-bellied Chloropsis

Taxonomy. *Chloropsis Hardwickii* Jardine and Selby, 1830, Nepal.
Nominate race and *malayana* intergrade in S Myanmar (N Tenasserim) and possibly more widely; these two are well differentiated from E races, but the two groups intergrade in N Laos, possibly also in SW China. Population in SC Vietnam (including Da Lat Plateau), currently included in *melliana*, may represent a separate, as yet undescribed race; further study required. Four subspecies recognized.
Subspecies and Distribution.
C. h. hardwickii Jardine & Selby, 1830 – N India (Himachal Pradesh) E in Himalayan foothills and hill tracts to S China (SE Tibet, Yunnan), Myanmar, NW Thailand and N Laos.
C. h. malayana Robinson & Kloss, 1923 – uplands of S Myanmar (N & C Tenasserim) and Peninsular Malaysia.
C. h. melliana Stresemann, 1923 – uplands of S China (from Guizhou and Guangxi E to Fujian) and of N & C Vietnam (S to S Annam).
C. h. lazulina (Swinhoe, 1870) – uplands of Hainan I.

Descriptive notes. 17–19·8 cm. Male nominate race has full black mask from lores and eye, extending to form broad bib down to upper breast, enclosing large jawline flash of shining violet-blue; anterior cap and narrow border around rest of mask subdued bronzy yellow; lesser wing-coverts out to carpal joint brilliant electric blue, other coverts, flight-feathers and tail deep black with dark purplish-blue edges; remaining upperparts grass-green; underparts below bib tawny-orange (may appear rich yellow in the field), upper flanks sharply demarcated green; iris dark brown; bill black; feet pale grey. Female has full yellow eyelid rim, duller jaw flash than male, smaller area of electric blue on wing, orange belly and vent, rest of plumage grass-green. Juvenile is entirely grass-green, apart from yellow eyelid rim. Race *malayana* differs from nominate only in small size, male wing 86–91 mm (nominate male 95–97 mm); *melliana* has cap blue-grey, rather than bronzy, and breast deep indigo, rather than black, female has underparts entirely green; *lazulina* differs from previous in having longer bill. Voice. Song, typically from open, treetop perch, the fullest and longest-sustained of family. In W races (both sexes), highly varied and melodious, with many ringing and doubled notes and phrases, e.g. "tshiwatshishi-watshishi-watshishi", "chitik joikjoikjoikjoikjoikjoik", "jijiju jirriju driju-driju", "cheat chewee-chewee-cheweei", "brechu préép brechu-brechu-choo-píá", "pitu-pitya-pitya-pitu", repeated "tyawit-tyatyawi-tya", or "easy easy jiep-jiep-jiep, chiwít-ta chiwít-ta chiwít-ta, weekweek-weekweekweek", or "kipper-kipper-kipper che ayeya-bing", "peer chee poot pee chip", etc.; much mimicry, including of, among others, bulbuls (Pycnonotidae), drongos (*Dicrurus*), green magpies (*Cissa*), minlas (*Minla*), sibias (*Heterophasia*), tits (Paridae), sunbirds (Nectariniidae) and spiderhunters (*Arachnothera*), tree-swifts (*Hemiprocne*) and Crested Serpent-eagle (*Spilornis cheela*). Calls include loud, rapid "ti-ti-tsyi-tsyi-tsyi-tsyi-tsyi-tsyi" followed by hoarse scold; slurred "fwéééw-whew", like that of an oriole (*Oriolus*); and, between foragers, a soft "choat", mewing "chair" and wheezing "frease". A realistic Streaked Spiderhunter (*Arachnothera magna*) flight-call simulation, "chittik", common at take-off.
Habitat. Canopy and edge of deciduous to evergreen forests, and secondary growth. Breeds between c. 600 m and 2000 m in Himalayas, above zone occupied by *C. aurifrons*; down to 500 m in W Myanmar but not necessarily breeding at that altitude, and generally not below c. 1000 m (wholly within montane forest) at lower latitudes.
Food and Feeding. Generalist; diet arthropods, fruits and nectar. Forages alone or in pairs, and sometimes joins mixed-species flocks. Gleans outer foliage and flowers for caterpillars, spiders (Araneae) and other arthropods, and chases winged termites (Isoptera), moths and butterflies (Lepidoptera) and other insects. Fruits, including figs (*Ficus*) and berries, eaten directly if small; medium-sized, tough-coated ones are pierced, and the bill then used to loosen and squeeze out contents. In N of range, one or more individuals, sometimes large parties, seek out flowering clumps and crowns of e.g. *Bassia* and larger-flowered mistletoes (*Loranthus*), often behaving acrobatically as they reach and probe into deep tubular corollas for nectar; individuals may patrol and defend a foraging patch. No flower-visiting reported in S of range, but assumed to occur there. Transferable pollen sticks to the face of flower-visitors, and this may explain silvery appearance of forehead often acquired by birds in Malaysia, even though no such foraging behaviour has been observed there.
Breeding. Nests have been found only in N of range, where Sino-Himalayan breeding season May–Aug. Shallow, open cup-nest of fine fibrous materials, sparsely lined and rarely with any external decoration, supported hammock-like at rim between thin twigs (not necessarily prongs of a fork) towards outer end of upper branch, typically 6–10 m up but a few records as low as 3 m. Clutches of 2 and 3 eggs recorded; no other information on wild-living populations; in captivity, incubation period 13 days, fledging period 12 days.
Movements. Altitudinal migrant in Himalayas, probably also in China and possibly in extreme N part of SE Asia; descends to plains level during winter in NE Indian Subcontinent.
Status and Conservation. Not globally threatened. Common in substantial parts of its range. An influx into Hong Kong since mid-1980s has been interpreted as natural expansion out of adjacent S China. Widely trapped for the cagebird trade, but this activity appears not to have had any serious overall effect on this species' numbers.
Bibliography. Class AVES

Order PASSERIFORMES

Suborder OSCINES

Family IRENIDAE (FAIRY-BLUEBIRDS)

- Robust, medium-sized arboreal frugivores with short tarsi, and strong notched and nailed bill; spectacular structural plumage colour, verditer to brilliant glistening blues, set off by black or indigo, and a blood-red iris.
- 21–27·5 cm.

- Oriental Region.
- Evergreen to semi-evergreen forest in lowlands and lower montane zone, ranging to forest edge and, locally, to certain plantation crops nearby.
- 1 genus, 2 species, 10 taxa.
- No species threatened; none extinct since 1600.

Systematics

Not since the 1920s have the fairy-bluebirds been treated as more than just a pair of species in a single genus, *Irena*. They are exclusive to the tropics of the Oriental Region and are assumed to be endemic there, although fossils are lacking.

Irenids entered the systematic record ahead of their allies, the leafbirds (Chloropseidae), and from a very different quarter, as the describer of the blue-backed bird from India believed it to be a roller (Coraciidae) and placed it in the genus *Coracias*. There the Asian Fairy-bluebird (*Irena puella*) remained until the 1820s, when its supposed affiliation was challenged by T. Horsfield and C. J. Temminck, who found nothing roller-like in the structure of fairy-bluebird specimens available to them from Java. Instead, they agreed on a likely relationship with the drongos (Dicruridae), an opinion that was seized upon widely and which held off a countering view for most of the rest of the century. This second view invoked the short foot of *Irena*, resembling that of a bulbul (Pycnonotidae), together with the possession of hair-like filoplumes among normal feathers of the nape, a character then considered diagnostic of bulbuls. These filoplumes were first noted in 1847 by the German taxonomist J. Cabanis, who switched his view accordingly. In that, he was soon followed by E. Blyth of the Calcutta museum in India, and Blyth appears to have been the first also to propose a further, special link with the leafbirds and the ioras (Aegithinidae). Support for this alternative view lived on in India but waned elsewhere, until resurrected in 1878, independently, by the Marquis of Tweeddale and by A. O. Hume. Papers by these authors may have influenced a key decision made by R. B. Sharpe to revise his entry in the *Catalogue of the Birds in the British Museum*, in which he separated irenids from the drongos in favour of a relationship with bulbuls, leafbirds and ioras, all of which at that time he actually believed to be babblers (Timaliidae). The drongo hypothesis effectively died at that point, but unnoticed in this change-about had been Hume's decision to place *Irena* at the end of his treatment of bulbuls, leafbirds and relatives, and to follow it directly with the orioles (Oriolidae). This action was to add another long, diverting strand to the group's history.

The notion of an exclusive, full-ranking family Irenidae is due to H. C. Oberholser, arch-splitter of his day, who, in 1917, rejected the bulbul-like features of fairy-bluebirds as being superficial, but offered no alternative ideas. In response, others picked up the oriole link. Hume's sequence choice may simply have been of a group of passerines of about the "right" shape and size, whereas a major regional publication by E. C. Stuart Baker, in 1926, gave the idea a fillip by claiming a likeness discovered between the juveniles of orioles and fairy-bluebirds. This was soon queried, although never explained (see Morphological Aspects). Nevertheless, it seems to have been enough to promote camps of support for an oriole relationship, remote from bulbuls and their supposed relatives, on the one hand, and, on the other, Sharpe's *Catalogue* arrangement, some versions of which extended to treating fairy-bluebirds, along with the leafbirds and ioras, as genera within a family Pycnonotidae. J. Delacour, in his 1960 treatment for J. L. Peters's *Check-list of Birds of the World*, joined the "bulbul camp", with a family Irenidae that included also the leafbirds and ioras placed next to Pycnonotidae. A. Wetmore countered this almost at once, citing sufficient structural divergence of the external nares, internarial septum, lachrymal part of the orbit, and secondary palate, for sundering *Irena* from all of these groups. He then proceeded to classify fairy-bluebirds as a subfamily of the Oriolidae, on the basis of a "general resemblance" of sternum and pelvic-girdle shapes, similarly glossy tips of the body feathers (no structure specified), and "lack of any important differences" between the two groups.

Since then, the impression has been of a dubious conclusion that the anatomist himself might never have been tempted to reach had oriolids not been on the historical taxonomic agenda. For convenience of reference, at least, something close to Wetmore's view still informs about as many modern handbooks and guides as does the bulbul hypothesis, but neither has fared well in the era of molecular taxonomy. C. G. Sibley and J. E. Ahlquist's DNA–DNA hybridization findings reconnected fairy-bluebirds and leafbirds, nesting both deeply and presumably, therefore, anciently within these authors' oscine parvorder "Corvida", with no claimed proximity to orioles, and well removed from the more recently diverged ioras. Subsequently, studies using nuclear-gene base-sequencing, carried out by F. K. Barker and colleagues in 2001, and reviewed by J. Cracraft and co-workers in 2003, suggest that the fairy-bluebirds and the leafbirds are indeed linked, but that both are remote from "corvidans" and should be transferred into Sibley and Ahlquist's other parvorder, "Passerida". Here, the data root them near the sunbirds (Nectariniidae), within a large family Passeridae, thus also well clear of the lineage containing the bulbuls. Leafbirds are now considered to be the fairy-bluebirds' closest allies, but

apparent time from divergence leaves a choice to be made between treating the two groups together or, as is often preferred, in two separate families.

Morphological Aspects

Fairy-bluebirds are indeed roughly the same in shape and build as a medium-sized Old World oriole, and they look more like orioles than like any generally smaller, more slender bulbul or leafbird. They are robustly built, in the approximate weight range 50–100 g. This rather large span, applicable to both species, is accounted for partly by sexual dimorphism, in which males average slightly larger than females, but more by geographical variation. The largest and the smallest subspecies of the Philippine Fairy-bluebird (*Irena cyanogastra*), namely the nominate race and *melanochlamys*, are a fair match for their Asian Fairy-bluebird equivalents, respectively the nominate subspecies and *crinigera*, and latitudinal trends in both species accord with Bergmann's Rule, *melanochlamys* and *crinigera* being the forms living closest to the equator. This parallel size variation is well demonstrated by the differences in wing lengths of males: in the Asian Fairy-bluebird, 13·1–14·0 cm in the nominate race of northeast India, as against 11·6–12·4 cm in southernmost *crinigera*; compared with the Philippine Fairy-bluebird, in which the northern, nominate race measures 12·9–13·8 cm, as opposed to southern *melanochlamys* at 11·6–12·2 cm.

The bill is powerful, proportionately more so in the Philippine species, and rather deep. It is also laterally compressed, although not extremely so, and among Asian Fairy-bluebird populations it is diagnostically least compressed in the small-island subspecies *andamanica*. Prominently notched and nailed, the bill is suited for gripping and squashing, well beyond the limit of leafbird variation and with none of the modifications that go with that family's protrusible, pumping tongue. The feet are rather small, unlike those of the orioles, and the tarsi are short even by bulbul standards. These characteristics suggest that irenids place less emphasis on foraging by climbing and reaching for food among foliage and that, by analogy with very short-footed forest birds of about the same body mass, such as some trogons (Trogonidae), they devote more effort to the fly-to/fly-past snatch, a technique that the Asian Fairy-bluebird is known to employ on long-stemmed fruit (see Food and Feeding).

Irenids are best known for their exceptional structural colours, extraordinary cobalt-blue, turquoise-blue and violet-tinted blue generated by specialized naked feather-tip barbs, with an enamelled brilliance particularly on the upperparts of male Asian Fairy-bluebirds. These colours cover most of the cap, the upper neck and all of the upper body, including the lesser and median wing-coverts, of adult male Asian Fairy-bluebirds, the cap, wing-covert tips and rump of Philippine Fairy-bluebirds, and the uppertail-coverts and undertail-coverts of both species. They are set off sharply by surrounding areas of deepest indigo to velvety black, and a bright red iris. The blues are a link with the leafbirds, but even in the less "flashy" Philippine Fairy-bluebird they are much more prominent, being permanently exposed, whereas they are mainly concealed in the relaxed, sleeked-down postures adopted by most leafbirds. In sunlight, with high UV radiation and against a dark, matt surround, the striking colours of the two irenids surely have special social signalling functions, even at a distance.

The main accepted difference between the Asian and Philippine Fairy-bluebirds is that the former is strongly sexually dichromatic and the other hardly so at all. Further, whereas isolation of leafbirds on oceanic parts of the Philippine archipelago produced henny males, as demonstrated by the Philippine Leafbird (*Chloropsis flavipennis*), isolation of fairy-bluebirds on several of the same islands did the opposite, either producing or sustaining cock-plumaged hens. The really interesting evolutionary question posed by the difference is which of the two plumage types, the bright blues and black or the near-uniform, matt verditer-green of the female Asian Fairy-bluebird, is primitive for *Irena* and which is derived. In deep forest shade, the proven nesting habitat of the Asian species, even strongly enamelled structural blues cease to be the give-away that they are in sunlight. Instead, it is black and deep indigos that show up, which is why, in a fleeting understorey glimpse, fairy-bluebirds of both species are often mistaken for an all-black, square-tailed drongo. Without this contrast, plain verditer female Asian Fairy-bluebirds are relatively cryptic when under shade. Now that aviculturalists have uncovered the extent of their role in nesting (see Breeding), it is hard to accept that a proto-*cyanogastra* stock lost a useful trait as a sec-

*Structurally, the **Asian Fairy-bluebird** combines features of Old World orioles (Oriolidae), bulbuls (Pycnonotidae) and leafbirds (Chloropseidae), all of which have been, at some time or other in its taxonomic history, considered close allies. In coloration, however, the male differs stunningly from these other families, his mixture of velvety black and luxurious blues offset by a crimson eye. The blue feathering is glossy and enamelled, an effect created by specialized naked barbs at the tips of feathers. Interestingly, the tail coverts are unusually lengthened in the races from the Sundaic region, though normal in the others; the reason for this is unknown.*

[*Irena puella malayensis*, Pulai, Peninsular Malaysia. Photo: Morten Strange]

*The female **Asian Fairy-bluebird** is a dowdy version of the male, with both black and blue portions replaced with dull verditer-green feathering. In this photograph, the blue tone has been picked out by flash, but it is much more subdued in the dim light beneath the forest canopy, often appearing merely blackish. Not only does the absence of gaudy plumage in females suggest that the bright colour of males is a sexual signal, but it also implies a need for camouflage that is greater in one sex than the other. This makes sense given that incubation is undertaken solely by females, on shallow flimsy nests: any bright colouring would render them conspicuous to predators. Like males, females have relatively short and stout legs, and they might be more easily mistaken for drongos (Dicruridae), were it not for their relatively short and simple tails.*

[*Irena puella.*
Photo: Konrad Wothe]

ondary development, unless, of course, some special advantage could have been gained from mimicking males. In effect, isolated island life may have helped *cyanogastra* to retain something of the primitive female fairy-bluebird condition, replaced completely in continental *puella* stock by a derived plumage that *cyanogastra* ancestors quite probably never had.

There is more to this deconstructive approach, following on from juvenile male Asian Fairy-bluebirds moulting into an only marginally bluer version of female-type plumage, as mentioned at the end of this section. It is notable that, although males of this species showing mixed immature and adult plumage are common in museum collections, only some of these specimens give evidence of having been in active moult when they were collected. Aviculturalists claim that captive male Asian Fairy-bluebirds held in the temperate zone start to moult into adult plumage at one year of age. In the wild, however, it appears that full acquisition of bright colours may often take more than one bout of moulting, thus perhaps even longer, hinting at delayed entry into the breeding population, if not delayed sexual maturity, a situation often associated with a non-monogamous mating system. Might some such system bear on the function of the gatherings of this species at a canopy fruit source, rendered conspicuous by persistent vocalizing; also, of single-sex parties of itinerants that show some social cohesion, as opposed to the possibly permanently paired behaviour of the Philippine Fairy-bluebird, gatherings of which are said not to exhibit cohesion? Where the harvesting of a large crop spreads over a few weeks, within which it may be possible to fit a breeding attempt, could Asian Fairy-bluebird males be operating a "mobile lek"? These are topics for basic research, but other, linked, questions follow (see General Habits and Breeding).

Finally, what can be made of the exaggerated development of the tail-coverts found in Sunda region subspecies of the Asian Fairy-bluebird? Both sets of coverts of both irenid species are everywhere highlighted by structural blues, implying that these parts are employed in some form of signalling behaviour. How the Philippine species behaves has not been recorded, but male Asian Fairy-bluebirds at a gathering persistently pump the tail up and down in a way that would ensure that the bright blue coverts are exposed from both directions. The function of the signal is unknown, but this action strongly resembles the tail-pumping of frugivorous pigeons (Columbidae) when aggressively defending a temporary feeding patch in the fruiting crown of a tree. They, too, show contrasting tail-covert colours, and some species gather at the same feeding sites as those frequented by fairy-bluebirds, implying a signal function that may even work across taxa.

What is unexplained is why the Asian Fairy-bluebird populations of Java, Sumatra and Borneo, subspecies *turcosa* and *crinigera*, have developed coverts long enough to encase the tail, above and below, to slightly beyond its tip, a feature rare among oscine passerines. Apart from the subspecies *malayensis* in the Malay Peninsula, which intergrades with the nominate race north to about the historical limit of Malayan-type rainforest, all other populations of this species, and all taxa of the Philippine Fairy-bluebird, have tail-coverts of normal length. This includes the Asian Fairy-bluebird subspecies *tweeddalei* of the Palawan group of islands, to the north-east of Borneo, perhaps as the survivor of a take-over by a new equatorial type of irenid. Why the Asian Fairy-bluebird should have evolved an apparent super signal within just one part of its range, without this having spread farther, and what additional functions this feature may have acquired, are still mysteries.

That leaves issues of plumage sequence, supposedly streaked juveniles, and a strange assertion that males of the Asian Fairy-bluebird acquire adult colours without moulting. Adult and post-juvenile irenid plumages are believed all to be more or less well known, whereas young juveniles receive hardly a mention in the literature from the field, and are conspicuously lacking in museum collections. Most information about the earliest stages of development, restricted exclusively to the Asian Fairy-bluebird, is derived from the monitoring of chicks hatched and reared in aviaries. A reconciling of several independent descriptions, by four authors, shows the nestlings to be thickly downy, the down initially greyish but darkening to dark brown or dark grey-brown as it develops, with the mouth-lining red or dark red, a black central spot inside each mandible, and the bill tip white. The first teleoptile feathers, those following the natal down, erupt on the head and upperparts on day five; they are verditer-green like the adult female feathering, but browner on the wings. The chick fledges with the underparts still downy but, specifically on the chest, now sooty black in colour, and the moult out of down to a fully verditer-green body plumage intensifies about one week later. The tail feathers are said to be narrower than those of adults, and the outer primary broader. At day 44, the young have been described by H. Knöckel, the one source on timing of the post-juvenile switch into a complete, all female-like immature or first-year plumage, as being about to enter a full moult.

The nestling of the Philippine Fairy-bluebird remains undescribed, and this species' juvenile stage is known only from a single fledgling collected with a pair of adults on the island of Leyte. Still growing the wings and tail, this individual appears to have moulted out of nestling down and is already adult-like, except for the fact that its tail-coverts show little blue, perhaps because they have not fully emerged. Whether either sex of this species then proceeds to a further pre-adult moult is unknown, but the quite probable answer is that neither does so.

No avicultural source mentions dark streaking at any stage of juvenile development, and Stuart Baker's claim that the young Asian Fairy-bluebird exhibits streaking resembling that of a juvenile oriole was clearly a misconception. This assertion has not been explained, but it may well have been founded on a plumage aberration fairly common in both sexes of all subspecies of this irenid, noticed a few times in the Philippine Fairy-bluebird, and widespread also in other groups of birds showing extensive structural blues and blue-greens, such as the pittas (Pittidae) and certain muscicapid flycatcher genera. The vane and shaft of the regular fairy-bluebird upperpart feather are uniformly blue or green. In some individuals, however, the shaft and the bases of the adjacent barbs lack or have reduced reflective material, so that these appear black or grey. The area in-

volved varies from just the shaft to, commonly, a long wedge of barb bases that expands on to the tip of the feather or, more rarely, to a large dot that fills most of both webs. In can occur anywhere, apparently randomly, but usually affects only a part of any one individual. The effect can sometimes be of streaks, but how Stuart Baker could have supposed this to be so only in juveniles is not obvious. It is difficult to understand how he missed it in fully adult males.

A notion that the male Asian Fairy-bluebird acquires blues by modification of the fully developed feather, without a moult, is attributed to E. W. Oates, a compiler of the bird volumes of the first edition of *Fauna of British India*. It was repeated by H. C. Robinson, in 1927, but has no known basis in fact. The explanation may have to do with immature males being just separable from females by the slightly broader apical fringe of blue that they show on the contour feathers. In adult males, verditer retreats to the deep, hidden base of the contour feathers, but its extent varies among individuals; in a minority, typically with some immature feathering retained, it does in fact just emerge to become visible behind the blue tip. A continuity of structural change from the immature condition may have been one interpretation of this variation, but the distinction between feather generations in the moulting post-immature male is perfectly clear, and it is hard to imagine how the idea really came about.

Habitat

Most field accounts of the Philippine Fairy-bluebird specify "original forest" as the species' habitat, and tall, more or less closed-canopy evergreen to not less than semi-evergreen, broadleaf lowland forest is the core habitat of both irenid species. In his exploration of Tenasserim province, in peninsular Myanmar, W. R. Davison remarked on the promptness with which the Asian Fairy-bluebird dropped out of the fauna as evergreen forest gave way to deciduous forest, only to reappear farther on as the latter reverted back to evergreen; this observation nicely illustrates this bird's critical dependence on habitat that is able to support fruit production throughout the year.

Hardly anything is known about the dispersal tendencies and capacities of the Philippine Fairy-bluebird, although J. Whitehead found that it visited forest of low stature, by which, it is guessed, he meant degraded forest. It is well known that parties of Asian Fairy-bluebirds are able to cross gaps between blocks of favoured forest, and also visit habitats such as peatswamp-forest, heath-forest and montane forest in which they do not breed or appear to remain for long, but which offer periodic fruit supplies. It would be reasonable to surmise that the irenid populations of nearby core habitat are aware of these food sources and that they monitor them. Certain kinds of berry-producing plantations, such as coffee with flowering shade, fall into the same category. For these relatively powerful, over-canopy fliers, the altitude extremes reached when searching, 1800–1900 m in the case of the Asian Fairy-bluebird and 1500 m for its Philippine congener, are potentially within daily travelling distance of the ecotone with core habitats. Incidental observations, however, suggest that it is more likely that profitable food sources are attended until they decline.

Most foraging by fairy-bluebirds is conducted at canopy level, dictated mainly by the whereabouts of the biggest crown-borne crops of bird-attracting figs (*Ficus*). Some forays extend to smaller, interior crowns of the middle stratum. The Asian Fairy-bluebird, at least, is also one of many canopy-living birds that descend deep into the shade layers of the forest in order to nest (see Breeding). Predation may be less in denser parts of the understorey and lower middle stratum, far from an interface. More certain advantages are the mechanical shelter and the stable, equable micro-climate that these offer by comparison with canopy conditions. Such factors may be especially beneficial when eggs are incubated, and perhaps nestlings brooded, by only one member of the pair (see Breeding).

General Habits

Fairy-bluebirds occur in pairs or in parties. Although single individuals occasionally join mixed-species foraging flocks, loners, at least of the Asian Fairy-bluebird, are an exception. On the island of Dinagat, in the southern Philippines, subspecies

For most of the year ***Asian Fairy-bluebirds*** *are essentially frugivorous. Within this definition, they are generalists, consuming fruit of a variety of types and sizes from a broad range of plants. It is thought that their mainstay, at least in the forests of South-east Asia, is the mass-fruiting of fig* (Ficus) *trees, a veritable bonanza which this individual is harvesting. Their requirement for a year-round supply of fruit restricts them to primary and tall secondary evergreen forest, although they will venture into nearby cultivated orchards when fruit is in season. They cannot survive in deciduous or semi-deciduous woodland, where fruiting patterns tend to be seasonal.*

[*Irena puella malayensis*, Singapore. Photo: Morten Strange]

hoogstraali of the Philippine Fairy-bluebird was observed to occur mainly in pairs. Even though numbers gathered at a fruit source, the party, when disturbed, dispersed in pairs that made off in different directions, implying no true flocking behaviour.

As discussed later (see Breeding), nothing is known of the breeding behaviour of the Philippine Fairy-bluebird, and little information is available on the breeding habits in the wild of Asian Fairy-bluebirds. The latter do appear to show quite strongly cohesive flock behaviour, and the general assumption had been that breeders dispersed to nest, after which they regrouped. What casual connection with groups they might maintain during nesting, and what level of pair relationship might persist after a return to social living, if that is what actually happens, both remained unknown. Overlooked in this scenario was the discovery by aviculturalists that the whole pre-hatch phase of the Asian Fairy-bluebird's nesting cycle is the province of the female alone. In addition, F. H. Sheldon and colleagues made the unexpected observation in northern Borneo that journeying flocks of the subspecies *crinigera* are often of a single sex. This backed yet another overlooked report, from Peninsular Malaysia, of parties exclusively of "females" of subspecies *malayensis* seen in the hill forest of Penang Island. The Bornean observation made no mention of which sex predominated in flocks, and verditer-green birds could, of course, have been immatures of either sex, thus introducing the possibility that dispersal behaviour is age-related. This was countered by a third record, of a party of ten visiting a fruiting banyan fig tree in Taman Negara National Park, in Malaysia, which specifically mentioned seven adult males, as well as the fact that this same, evidently stable combination of birds returned to the site repeatedly.

The possibility that prolonged socializing by this species really is at least weighted by sex, as stated, has implications for mating systems and breeding stategies. Nesting by captive Asian Fairy-bluebirds artificially isolated as pairs in aviaries, even though sometimes successful (see Breeding), may not have supplied the full story, and the slightness of sexual dimorphism in the Philippine Fairy-bluebird now suggests a bigger biological difference between the two species than had been suspected.

Both irenids are active birds. Their powerful, direct flight through and above the forest canopy gives them the potential for fast dispersal, where needed across habitat gaps, and potentially for long distances. Such behaviour is confirmed in the case of the Asian Fairy-bluebird, and is a clue to the modelling of this species' most likely general ecology, that of trap-lining around the known resources of a largish, shared range. Basic observations on the Philippine Fairy-bluebird seem still to be lacking.

Voice

Foraging pairs and parties of both irenid species give away their presence at a distance by frequent contact calls. These are loud, resonant but distinctively liquid monosyllabic and disyllabic whistles that carry far, including through foliage from the high canopy of forest. In the case of the Asian Fairy-bluebird, extra calls of similar sound quality come in as birds fly together in a group, but no equivalent calls have been described for the apparently less social Philippine species.

Other, longer vocalizations in which sounds of contact call type are strung together with a few added elements have been termed "song", but this classification is structural rather than functional, being based simply on complexity and duration of the vocalization. The Philippine Fairy-bluebird has been described as a fine singer. It is also said to be a good mimic of drongos and bulbuls, although E. C. Dickinson and colleagues remarked on the mimicking of this species, and of the Philippine race *tweeddalei* of the Asian Fairy-bluebird, by drongos themselves, specifically by the Balicassiao (*Dicrurus balicassius*) and the Hair-crested Drongo (*Dicrurus hottentottus*). The unscrambling of vocal mimic from model may not be straightforward.

Noisy Philippine Fairy-bluebirds, at least of the subspecies *ellae* and *hoogstraali*, can easily be attracted by a whistled imitation of their calling. That they take up a treetop station immediately above the sound source suggests that certain of their calls have a defensive function. No such claims have been made for the Asian Fairy-bluebird, although several participants in a gathering of foragers may "sing", or counter-sing, and some of this species' vocalizations have been placed in context from observations on individuals in aviaries. As defined, songs are exclusive to males. A "uiiit-uiiit-uiiit-uiit-uiit-uit-uit-uit" call is given regularly at dawn, and "do-re-me-hew-hew-hew" and a "wank" series, covering more than one subspecies, are likely to be no more than other renderings of this same call. Sounds linked directly with sexual display include one at the start of courtship which has been likened to a loud version of the long whistling vocalization of the Common Starling (*Sturnus vulgaris*), with "uit" notes interjected. Others, given during posturing to expose the dorsal blues, and with the body and tail vibrated and rocked from side to side, include a shrill, scratchy squeak and a "wii-dip-wii-dip-dip-wii-dip" sequence. A "whit-tu, whit-tu, whit-tu, whit-tu", recorded from the field as accompanying tail-pumping in which the tail-covert colours are flaunted, is surmised to be another impression of the same call, adding interesting possibilities with regard to the function of this behaviour.

Food and Feeding

In captivity, nestling Asian Fairy-bluebirds fed entirely by the parents developed and fledged successfully on a wholly insect diet, comprising mealworms, crickets (Tettigoniidae), caterpillars and moth pupae. Supplementary fruit was offered in one instance on day five, but otherwise apparently only after fledging. In the wild, some animal food continues to be taken into adulthood, at least by this species. Representatives of inner tropical populations have often been found in mixed parties of insectivores foraging at middle and canopy levels of forest, the subspecies *malayensis* and *crinigera*, and doubtless others, hawk termites (Isoptera) from nuptial swarms, and crop contents of Bornean *crinigera* have confirmed the taking of termites, ants (Hymenoptera) and beetles (Coleoptera).

On the other hand, after fledging, fruit, especially figs, is certainly the main food of both species, apparently throughout their respective ranges. Most *Ficus* species are dispersed by vertebrates and, at community level, in the kinds of humid environments supporting evergreen forest as opposed to deciduous growth, they parcel out the attentions of frugivores by staggering their crops through the year. On one 200-ha plot of the Kerau Wildlife Reserve, in Peninsular Malaysia, F. R. Lambert recorded fairy-bluebirds at 22 of the 25 bird-attracting species under study, these cropping from the middle stratum to the top-canopy level, and bearing fruit in the diameter range 5·4–27·7 mm. Other species have been added to the food list at other sites, and non-fig foods range across berries and drupes of many sorts, down to tiny, mass-produced fruits such as those of the forest-edge euphorb *Trema tomentosa*.

As revealed from the contents of stomachs, some items are fruits with large to very large seeds. It is assumed that such seeds, rather than passing through the gut, are regurgitated directly, and on average at a distance from the mother plant, given that parties of Asian Fairy-bluebirds typically retreat from the food tree between feeding bouts. The occurrence of oil palm (*Elaeis guineensis*) nuts in one or more stomachs of subspecies *crinigera* in Borneo suggested the experimental taking of an inappropriate food that probably could not have been processed unless first broken up. This is not a known type of behaviour of the Asian Fairy-bluebird, the typical action of which is to crush fruit before swallowing it, thereby raising the limit of manageable fruit size rather than its processability. It also demonstrated that the birds make visits to plantations, probably on the edge of forest, and reports of the taking of coffee berries (see below) demonstrate the opportunistic nature of fruit-finding by this species. Force would have been needed to extract an item from a fruit bunch of an oil palm, and this irenid normally perches only in order to deal with toughly attached items. Its main harvesting behaviour, akin to the taking of swarming termites, is the fly-up-to or fly-

Although the diet of adult fairy-bluebirds consists largely of fruit, they also consume a small but consistent amount of insect matter, such as beetles and alate termites, as demonstrated by this ***Asian Fairy-bluebird****. In common with many frugivorous birds, adults are unable to provision their brood with fruit because the mineral and protein content of such a diet is too low to sustain the growth of nestlings. Instead, if the evidence of captive birds is anything to go by, young fairy-bluebirds are fed a variety of insects, and only begin consuming fruit once they have fledged. To these ends, the irenid bill is robust and powerful, laterally compressed, and prominently notched and nailed, a design which not only helps in manipulating fruit, but also in catching and gripping insect prey.*

[*Irena puella andamanica*, Havelock Island, Andamans. Photo: Konrad Wothe]

past snatch, allowing the gathering of berries, such as those of *Eurycoma* (Simarubaceae), that grow on flimsy stems or long, hanging pedicels. Irenids have none of the pulp-sucking adaptations of the leafbirds, but they do have a more powerful bill, this being especially marked in the case of the Philippine Fairy-bluebird (see Morphological Aspects).

Two further, probably connected aspects of behaviour, both of the Asian Fairy-bluebird, deserve mention under this heading. One is the taking of nectar from large tree-crown blossoms, *Erythrina* and *Grevillea* species being the usual ones cited. The avifaunal literature of the Indian Subcontinent refers to this behaviour routinely, but no mention of it has been found in any primary source for this irenid in South-east Asia, and no reference at all has been found to flower-visiting by the Philippine Fairy-bluebird. The other concerns the alleged habit of Asian Fairy-bluebirds of regularly going to ground. This was described originally by Davison, in Tenasserim: "In the middle of the day they habitually come down to the banks of streams and the smaller rivers to drink and bathe." Widely copied on in secondary sources, this claim was flatly contradicted by Robinson, who stated that this species never comes to the ground. Specimen collection dates show that Davison's Tenasserim expeditions were all limited to dry seasons, whereas Robinson wrote of the ever-humid Malay Peninsula. The present author's own experience of the Asian Fairy-bluebird in Malaysia is of never having seen one on the ground, and of capturing some in a ground-set mist-net only once, close to a permanent pool in forest during an exceptional El Niño drought. It seems probable that nectar and forest streams constitute reliable emergency sources of liquid when the more usual supply of arboreal water, trapped in knotholes and similar places, runs out.

Breeding

Philippine Fairy-bluebirds with active gonads have been recorded in March, April and May, and a fledgling of the subspecies *ellae* is dated 5th August. P.C. Gonzales and C. P. Rees alone implied other knowledge of the species' breeding biology, in their 1988 introduction to the national avifauna, but these authors stated merely that the nest is cup-shaped. Otherwise, this irenid's habits and behaviour remain unknown. Asian Fairy-bluebirds in the Indian Subcontinent breed over the period January to June, with peak incidence during February to April. In northern Borneo, gonadal condition of specimens indicated breeding in December and February–August, and in Java nests have been found during October–May.

Most details of the breeding behaviour of the Asian Fairy-bluebird derive from observations made on captive birds. Pairs isolated in aviaries allopreened and called in unison. Male sexual display included presentation of the sleeked-down glossy blue upperparts as the scapulars were raised, vibration of the body and tail, with side-to-side movements that might alter the reflectivity of enamelled gloss, neck-stretching, and head-jerking with the cap feathers ruffled and the bill open, accompanied by song and an intensification of the red of the iris. There are reports from the field of males in gatherings vocalizing while persistently pumping or flipping the tail, thereby flashing the brightly coloured tail-coverts, but whether this behaviour is linked to sexual display as opposed to some other form of social signalling (see Morphological Aspects) has not been investigated. Only one aviculturalist's description mentions it, as a male signal to its mate during breeding, but this was not clearly in a courtship context.

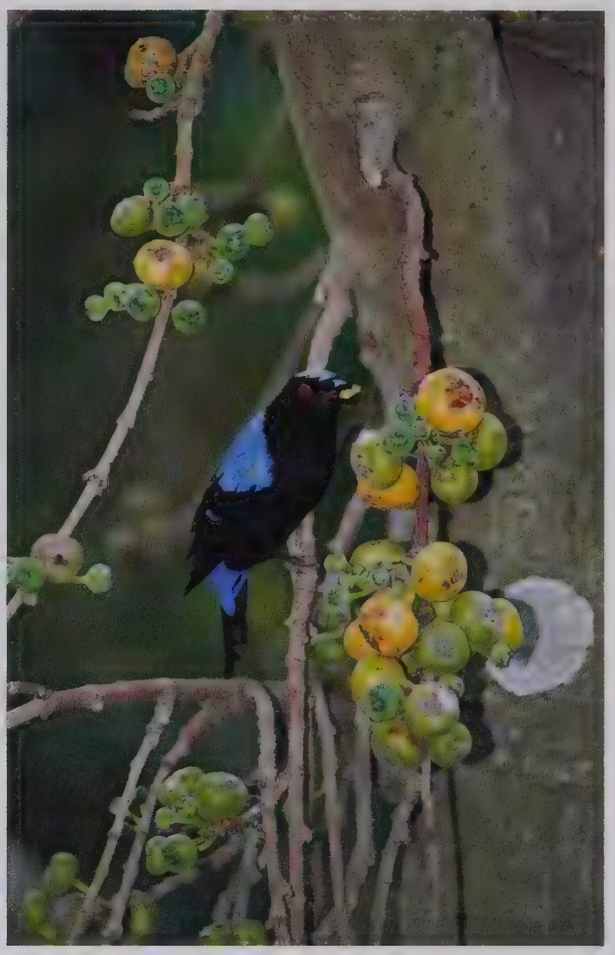
The male's role, if any, in selecting a nest-site is unknown, but aviculturalists breeding Asian Fairy-bluebirds in aviaries all agree that nest-building, including the collection of materials, is undertaken by the female alone, her mate calling nearby but not visiting. In the wild, all reported nests of this species have been found in relatively dense, shaded parts of the understorey up to, but not above, the lower middle stratum of tall, closed-canopy forest. Built into the fork of a sapling or on a palm frond 2–6 m above ground, they are said to be small for the size of the bird, externally no more than 12 cm across, and formed into an unusually shallow saucer constructed mainly from twigs. The structure is flimsy enough to be seen through, making it difficult to spot nests from below, or camouflaged externally with green bryophytes, the egg-chamber often being lined with the

same material. The nests of the subspecies *malayensis* and *tweeddalei* have not been described.

One captive Asian Fairy-bluebird laid consecutive clutches of three eggs, but only two of either hatched, and in the wild, over the whole latitudinal range of the species, recorded clutches and broods have never been of more than two. The eggs are longish ovate in shape. They have a ground colour of pale grey-green or, exceptionally, buff, and are flecked all over to, more rarely, mainly over the broad end with brown, grey-brown and purple-grey. According to Stuart Baker, they measure 30·7–25·3 x 21·3–18·9 mm.

The female alone incubates, and the interval from egg-laying to hatching, measured in captivity, is 14 days. The young are fed mainly or wholly on insects, and they fledge mostly on their thirteenth day, extremes being 11 days and 18 days. Accounts of parental roles in aviaries vary, from all brood-tending being performed by the female alone, without any help from the male, to both sexes participating from hatching, and even to the bulk of chick-feeding duties being undertaken by the male. In one instance, recorded by L. Haye, within a single season, a male switched from taking no part in the rearing of the first brood to helping with the raising of the second-brood young. How this ties in with the behaviour of irenids in the wild, of course, is still unknown.

Not all aviary pairs are successful. In one of several captive-breeding episodes in France, an attempt was made to foster a rejected Asian Fairy-bluebird chick outside the aviary, in the nest of a wild pair of Eurasian Blackbirds (*Turdus merula*). The experiment was a success, apparently, until at a late stage the brood was raided by a garden dormouse (*Eliomys quercinus*).



J. Stewart, who collected many nests of Asian Fairy-bluebirds in south-west India, claimed that on two or three occasions he found clutches with an egg of the Common Hawk-cuckoo (*Cuculus varius*). This is surprising, as the interior of evergreen forest, the nesting habitat of this irenid, is not where this particular parasitic cuckoo would be expected to occur. Identification seems to have rested on eggs alone and should be treated with caution, pending additional information.

Movements

Because of the nature of their habitat, fairy-bluebirds have rarely been mist-netted, very few indeed have been ringed, and no record has been found of any distant recovery of a marked individual. An understanding of their dispersal strategies has been pieced together from random, incidental observations only, and hence can be no more than provisional.

Irenids are powerful fliers, travelling fast through and above the forest canopy, and the Asian Fairy-bluebird, at least, is able and willing to cross ecological barriers, including tracts of non-forested habitat. The latter may stretch to sea gaps if it is reasonable to assume that records of this species from some little islands off the coast of the Malay Peninsula involve visitors rather than permanent residents, but no cross-water movements have been confirmed. A generalized model of how these birds live is suggested above (see General Habits), but it is not known what distances they actually travel between successive feeding stations, and not even a guess has been hazarded as to how large a patch they patrol over longer, seasonal or annual, timespans.

Although fairy-bluebirds do disappear locally, they are rarely absent from a given site for long, they never feed far from forest, and no record has been found of any having been intercepted while dispersing at night. There is no reason to believe, therefore, that either species is truly nomadic in any part of its range. S. Ali and S. D. Ripley, in the second edition of their *Handbook of the Birds of India and Pakistan*, mentioned the seasonal occurrence of Asian Fairy-bluebirds on the Coorg Plateau of the Western Ghat Range, where the species is said to be a winter dry-season visitor. Its appearance there, however, may involve no more than local upward movements off neighbouring slopes, as occurs among presumed trap-lining foragers elsewhere in the species' range. No difference may exist between this phenomenon and the intermittent visits made by other populations to montane forests of less seasonal South-east Asian mountains, over similar elevational spans and within believable daily ranging distances.

In general, fairy-bluebirds forage in the canopy, but they do visit the darker reaches of the middle and lower storeys to nest, and to harvest supplies of fruit. In this instance, a male ***Asian Fairy-bluebird*** *has descended to fruit that is developing close to the stem of a forest tree, a phenomenon termed cauliflory. This individual is making use of a convenient perch adjacent to the fruit itself, in this case figs* (Ficus)*, but when food is less accessible it is common for irenids to hover momentarily and snatch fruit in flight before returning to a perch. This photo also reveals that large fruits are not taken whole, but nibbled when ripe.*

[*Irena puella puella*, Thailand.
Photo: Roland Seitre]

Periodic altitudinal excursions to exploit well-synchronized flower and/or fruit crops would be expected in many parts of the family's range, much as visits are made to exploit occasional mass fruitings in exceptional types of inner tropical lowland habitat, such as heath-forest, which are otherwise avoided. Patterns of fruit availability in forests on the comparatively fertile, volcanic soils of much of the Philippines, on the other hand, could mean that the Philippine Fairy-bluebird has had less need to travel.

Relationship with Man

Despite the gaudy appearance of the two fairy-bluebirds, they seem not to have any special human cultural connotation or, at least, none that has come to light. Before the great days of rubber and oil palm, pioneer planters in the Malay Peninsula grew lowland coffee under original or planted shade, on gardens or small estates cut directly out of mature forest. As told by W. T. Page in 1913, they knew the Asian Fairy-bluebird well, as "the Coffee Bird", for its raids on their berry crops. Nowhere is there any allusion to this species' former status as an actual pest, but its visits to a sudden, plentiful addition to the regular round of neighbourhood fruit supplies must have been common and obvious enough to have generated the special name. Identification of the fruit of oil palm in the stomach contents of fairy-bluebirds from Borneo (see Food and Feeding) was a surprise, however, as fairy-bluebirds are hardly known as visitors to palm plantations.

Not surprisingly, the main human interest in these birds has been aesthetic, as cagebirds, within the region and also in international trade. Private aviculturalists and several zoos in Europe and America have kept, bred and raised fairy-bluebirds successfully in aviaries, although all published accounts available refer just to the more spectacular Asian Fairy-bluebird, and all but one to its nominate race, the sole exception being one about the western Philippine subspecies *tweeddalei*.

Status and Conservation

Treetop-foraging parties of irenids tend to give themselves away by their loud, far-carrying contact calls (see Voice). This noisiness, and the regularity of their attendance at mass fruitings have been elements in the perception of these birds as more or less common to actually very common over most of their respective ranges. On Palawan, in the early twentieth century, the subspecies *tweeddalei* of the Asian Fairy-bluebird impressed W. P. Lowe as being one of the commonest or, at least, most visible forest birds of the island, and the Sumatran literature includes an account of a daily movement by hundreds of individuals of the subspecies *crinigera*. These reports date from before the days of large-scale timber extraction and the mass onslaught on South-east Asian lowland forest cover, but in the 1980s Sheldon and colleagues were still able to describe *crinigera* as commuting in "large flocks" between blocks of Sabahan forest, in northern Borneo. No such numbers have ever been described from anywhere in the range of the Philippine Fairy-bluebird, a contrast noted by the explorer-naturalist J. Whitehead more than a century ago, in the 1890s, hence hinting at some ecology-based difference rather than a direct status issue. Even now, field contacts with both species range from routine to at least not exceptional, and neither receives a mention in recent BirdLife International Red Data publications covering the birds of Asia.

The situation of taxa below species level is less comfortable, given that more than 90% of the global habitat space for some fairy-bluebird subspecies has been lost outright to deforestation, and the rest seriously fragmented. Visible they may still be, but common sense rejects the possibility that no serious damage has been done to these birds at population level. Indeed, over the past century, all four subspecies of the Philippine Fairy-bluebird have vanished from most of their recent ranges owing to habitat loss. The prognosis for what suitable forest remains suggests that all of them should be placed in the conservation category of Near-threatened, if not that of Vulnerable. In the case of the Asian Fairy-bluebird, massive loss of habitat, coupled with rising pressure from hunting with guns, makes it unlikely that the Javan subspecies *turcosa*, *crinigera* in Sumatra and Philippine *tweeddalei*, at least, have not already reached one or the other of those two categories. Even in forest where timber production is carried on sustainably, the common sylvicultural practice of removing large, canopy-cropping *Ficus* species has a disproportionately high impact on frugivores reliant on figs as a key food source (see Food and Feeding).

In the background to this lies the mystery of the disappearance of the Asian Fairy-bluebird from Sri Lanka, from an area potentially larger than the historical ranges of some still extant, even still common, taxa elsewhere. Recorded observations, all in the ever-humid south-west quadrant of the island, date from the era of first exploration by ornithologists, from the 1840s to 1877, although the latter year may not, of course, have been the one of actual biological extinction. Opinion on the species' status in Sri Lanka has varied. A recent edition of G. M. Henry's *Guide to the Birds of Sri Lanka*, published in 1998, pointed out that fairy-bluebirds are even now imported as cagebirds, implying that the release of exotic captives for merit in a Buddhist stronghold would have been likely, but without then considering why this practice should have stopped. Others have suggested that Sri Lanka received migrants, presumably from India; but fairy-bluebirds are absent from the south-east Indian presumed area of departure and landfall, and for good ecological reasons. If such journeys ever really did occur, they would need to have been a good deal longer than just the sea-crossing.

Although there have been a few vague claims of Asian Fairy-bluebirds being observed in Sri Lanka in the twentieth century, no reliable evidence of a wild/free-living presence of the species on the island dates from later than the 1870s.

The real issue here is that populations are constrainable at any point in their annual cycle. The scenario suggested is that nineteenth-century recorders witnessed one already in the last stages of running out of fuel as its humid-forest biome gave way to other land uses, notably spice-planting, an industry established in that quarter of Sri Lanka even before the end of the eighteenth century. Conventionally, individual survival is understood to be a matter of energy uptake traded against expenditure, including that on its procurement. Fragmentation of fairy-bluebird habitat by deforestation has several adverse effects: it randomly removes customary ports of call for foraging, forcing a search for replacements cropping on a similar cycle; progressively, it reduces the options for such replacements, thereby expanding the required minimum search area; finally, as habitat patches shrink and retreat, it stretches searching/journeying time versus feeding time to the point at which the daily budget ceases to balance. Some tropical Asian forest frugivores compensate for the scope of their travel by shifting it to the night, but fairy-bluebirds are not known to do so (see Movements). What that conjures up is a picture less of a slow dwindling-away than of whole subpopulations shifting rather suddenly from a position of having just got by, perhaps with breeding or migration capacity impaired, to one of going rather suddenly, collectively, past the point of no return.

This is no more than a model of an explanation, but is one that could have applied to Asian Fairy-bluebird history elsewhere in the Indian Subcontinent, where southern and northern populations of the nominate race are suspected of having lost contact as suitable forest habitat became fragmented and shrank. A. Sondhi mentions the disappearance of this bird around 1990 from one intermediate relic, Bimashankar Wildlife Sanctuary, a still rich but isolated block of evergreen forest north-west of Pune, in the state of Maharashtra. Globally, this subspecies happens to have much space left, but the idea could be important for projecting what may be about to happen to other, more restricted irenid taxa suffering habitat loss elsewhere. Standing numbers alone are unlikely to be a sensitive indicator of conservation status.

Both species of irenid are locally common, but the ***Philippine Fairy-bluebird*** *is restricted to the increasingly man-modified landscape of the Philippine archipelago, and must have suffered severe population declines as a result of deforestation and hunting. The reliance of both species on fruiting trees, a resource that fluctuates in space and time alike, increases the likelihood of local extinction when forests are broken up into ever-receding fragments. In all cases, the area of suitable habitat under protection should be expanded, and fairy-bluebird populations, especially those already isolated, should be monitored carefully.*

Genus *IRENA* Horsfield, 1821

1. Asian Fairy-bluebird

Irena puella

French: Irène vierge **German**: Türkisfeenvogel **Spanish**: Irena Dorsiazul
Other common names: Blue-backed/Blue-mantled Fairy-bluebird; Palawan Fairy-bluebird (*tweeddalei*)

Taxonomy. *Coracias Puella* Latham, 1790, Travancore, southern Kerala, India.
Formerly considered conspecific with *I. cyanogastra*. Race *andamanica* treated as synonymous with nominate by some authors, but differs in having heavier bill. Birds from N Indian Subcontinent, described as race *sikkimensis*, considered better treated within nominate. Body size varies with latitude, outer tropical populations of nominate being largest, equatorial *crinigera* smallest. Race *tweeddalei* has sometimes been spelt *tweeddalii*, following very slightly later usage by same author; latter, however, must be rejected as unjustified emendation or incorrect subsequent spelling. Six subspecies recognized.
Subspecies and Distribution.
I. p. puella (Latham, 1790) – SW, S & NE Indian Subcontinent E to extreme S China (S Yunnan), S in continental SE Asia to N Malay Peninsula and S Vietnam.
I. p. andamanica Abdulali, 1964 – Andaman and Nicobar Is.
I. p. malayensis F. Moore, 1854 – S Malay Peninsula.
I. p. crinigera Sharpe, 1877 – Sumatra (including islands off W coast), Bangka, Belitung and Borneo.
I. p. turcosa Walden, 1870 – Java.
I. p. tweeddalei Sharpe, 1877 – W Philippines (Calamians, Palawan, Balabac).
Descriptive notes. 21·2–25·8 cm; male 56·6–75·7 g, female 52–71·2 g (*malayensis*). Strongly dichromatic. Adult male nominate race has frontal band over bill base, conjoined lores and side of head to well above eye, side of neck, entire underparts (except undertail-coverts), wings (apart from lesser and median wing-coverts) and tail deep black; remaining plumage, including tips of tertials, brilliant blue, "enamel-glossed" especially on cap and upperparts by modified outer barbs; hidden bases of these blue feathers variably (non-glossed) verditer-green to, on upper neck, black; some individuals have black or grey shaft streaks on body and/or upperwing-coverts; iris bright blood-red; bill all black; feet black. Adult female (some with dark shaft streaks, as male) has head, body and upperwing-coverts, tertials and central tail feathers subdued verditer-green, feather edging slightly bluer (hence slightly brighter) on rump, uppertail-coverts and underparts; remaining plumage sooty brown, verditer only on outer webs of other tail feathers and on external edging of flight-feathers; iris paler, brick-red or orange-red. Juvenile is like female, except that wings are all brown, iris brown; plumage soon replaced, immature closely resembles female (male slightly bluer) and safely separated only by browner iris colour. Races vary mainly in colour tone of blue parts of adult male, and tail-covert shape and length: *andamanica* differs from nominate by heavy bill, broader and marginally deeper than in any other race; *malayensis* resembles nominate, but tail-coverts longer; *crinigera* is smallest, tail-coverts completely encase tail, above and below, to slightly beyond its tip; *turcosa* has tail-coverts as previous, but is on average slightly larger; *tweeddalei* is distinctive, male blue areas cold azure to turquoise-blue (rather than violet-tinted royal blue), other age/sex-classes duller. Voice. Various liquid, whistling monosyllabic and disyllabic contact calls, strident and carrying: nominate race "weet weet", "be-quick", "what's it", "djü-djüt", "uiiit", "tui, wit-weet" and similar, also "which-ip which-ip which-ip"; *malayensis* "wait" or "whi-it" or "whit, whet, whit". Flight calls "chichichichik", repeated every few seconds, a repeated "chir-ip", also "twing-twing" or "wit wit wit". Possible songs or song elements by male: "tu-lip wae-waet-oo", "do-re-me-hew-hew-hew", "uiiit-uiiit-uiiit-uiit-uit-uit-uit-uit", "whit-tu, whit-tu, whit-tu, whit-tu" with tail-jerking (all nominate); wavering "u-iu" (*malayensis*); 7–8 "wank" sounds which descend slightly and become broader, more profound towards end (*crinigera*); "wheep-wheep pul paaawwww", phrase 1 second long, repeated serially, and "hu we-u whíp-tip hu wee-u" (*tweeddalei*). Male nominate race during courtship display "wii-dip-wii-dip-dip wii-dip...", and whistle like that of Common Starling (*Sturnus vulgaris*). Also, a hoarse "chrroachch" croak between pair-members at close quarters, and thin "wi-wi-wi..." from a female (with bill closed) when resisting being displaced.

Habitat. Tall tropical to subtropical lowland broadleaf evergreen to semi-evergreen forest, and comparable montane forest; from plains level to 1800 m in Indian Subcontinent (Western Ghats, E Himalayan foothills of Bhutan), but generally lower in N (to 1200 m in Sikkim, 850 m in Nepal); occasionally to 1900 m in Malay Peninsula, but everywhere much commoner below montane ecotone. Avoids deciduous forest, but recorded as visiting low-stature heath-forest in Borneo and

degraded forest in parts of Sumatra; emerges from regular habitat into scattered trees of tea estates and shade cover of coffee plantations cut out of forest, presumably where tempted by a flowering or fruiting event.

Food and Feeding. Diet mainly fruit, ranging from small berries to figs (*Ficus*); also nectar in more seasonal parts of range, but nectar-feeding unrecorded in humid inner tropics; alate termites (Isoptera) also taken. Food of wild nestlings unreported; in captivity, chicks have thrived on a diet exclusively of live insects delivered independently by parents, with fruit offered mainly after fledging. Fruits taken while perched or in a flying snatch, mainly in middle stratum and canopy of forest; termites caught in air. Regularly joins mixed-species parties of insectivores hunting among foliage. Raids coffee berries.

Breeding. Season Jan–Jun, peak Feb–Apr, in Indian Subcontinent; mainly on gonad condition of specimens, Dec and Feb–Aug in N Borneo (Sabah), and Oct–May in Java. Nest, built by female, a relatively small, unusually shallow, flimsy open cup of twigs and bryophytes, placed 2–6 m up on sapling fork or palm frond in shaded understorey to lower middle stratum of forest. Normal clutch 2 eggs; in captivity, incubation by female alone, period c. 14 days, nestlings tended by one or both parents, fledging period c. 13 days (extremes 11–18 days). Reported brood parasitism by Common Hawk-cuckoo (*Cuculus varius*) in S India thought unlikely on grounds of habitat, requires verification.

Movements. Essentially resident. Said to be a seasonal (winter) visitor to Coorg Plateau, in Western Ghats (SW India), but this may not involve more than local upward movements off neighbouring slopes. Records from some tiny islands of SE Asian continental shelf presumed to involve only visitors, but no cross-water movements confirmed.

Status and Conservation. Not globally threatened. More or less common through most of range; only locally uncommon or rare. Formerly occurred in Sri Lanka; apparently, disappeared from there in late 19th century. Massive loss of habitat, and increasing hunting pressure with guns, have led to significant declines in Java (race *turcosa*), Sumatra (*crinigera*) and W Philippines (*tweeddalei*); populations in those regions, at least, require re-assessment of conservation status, probably already Near-threatened or even Vulnerable. Removal of large, canopy-cropping fig trees, a common sylvicultural practice even in forest where sustainable logging carried out, has disproportionately high impact on frugivores reliant on figs as a key food source. Effects of trapping for cagebird trade not known.

Bibliography. 2. Philippine Fairy-bluebird

Irena cyanogastra

French: Irène à ventre bleu **German**: Kobaltfeenvogel **Spanish**: Irena Dorsinegra
Other common names: Black-mantled Fairy-bluebird

Taxonomy. *Irena cyanogastra* Vigors, 1831, Manila, Luzon, Philippines.
Formerly considered conspecific with *I. puella*. Species name sometimes given as *cyanogaster*, but this is an unjustified emendation. Four subspecies recognized.

Subspecies and Distribution.
I. c. cyanogastra Vigors, 1831 – Luzon, Polillo and Catanduanes.
I. c. ellae Steere, 1890 – Samar, Leyte and Bohol.
I. c. hoogstraali Rand, 1948 – Dinagat and Mindanao.
I. c. melanochlamys, Sharpe, 1877 – Basilan.

Descriptive notes. 23·3–27·5 cm; male 71–96·1 g and female 75·9–89·7 g (*ellae*), two males 72 g and 76 g and four females 69·4–78·4 g (*hoogstraali*). Adult male nominate race has frontal band above bill, lores, face to well above eye, side of neck, and chin, throat and upper breast deep black, with only slight sheen; rest of cap rich, glossy royal blue with violet tinge, colour petering out on upper neck; rest of neck, scapulars and whole upper body deep indigo-blue, progressively more broadly tipped glossy royal blue from rump to uppertail-coverts; lesser and median wing-coverts blue-black, broadly tipped glossy royal blue; greater coverts black, outer webs of inner part of tract royal blue but darkening descendantly and blue retreating towards outer-web tip, leaving outer tract all black; alula and primary coverts all dull black; central pair of tail feathers dull indigo, blackening towards tip, rest of tail black, except outer webs of T2–5 indigo with brighter fringes; underparts below breast deep indigo; undertail-coverts deep indigo-blue, broadly tipped glossy royal blue; iris blood-red; bill black; feet black. Adult female resembles male but slightly duller, demarcation of ventral indigo against black less sharp; one individual with dark shaft-streak aberration on cap. Fledgling still growing flight-feathers and tail is adult-like, but less blue on still-growing tail-coverts; other pre-adult plumages undescribed. Races vary chiefly in extent of black (versus indigo) on upperparts (none in nominate) and underparts: *ellae* has upper neck, mantle and scapulars black, chin to rear-flank level black, rectrices without brighter fringes, female indigo below breast; *hoogstraali* has upperparts and tail as previous, black below only down to breast; *melanochlamys* differs from last only in smaller size. Voice. During presumed breeding season very noisy, and a mimic; apparent song "whip whip whip-aaww" or "weep weep weep paw", repeated directly or at intervals, often several birds calling together. Responds to whistled imitations of contact calls and approaches human caller.

Habitat. Tall, mainly closed-canopy lowland broadleaf evergreen forest, and equivalent lower montane forest, from plains level to c. 1500 m. Forages out to forest edge; recorded also as visiting "lower growth" (= degraded forest?) on Leyte.

Food and Feeding. Confirmed items include only fruit, especially figs (*Ficus*), but diet unlikely to differ much from that of *I. puella*. Forages almost wholly in top canopy, even more so than *I. puella*, venturing also to fruit crops at forest edge. Fruits searched for probably by trap-lining around known sites, but perhaps not socially, as gatherings at food sources seem not to behave as cohesive flocks.

Breeding. Adults with active gonads in Mar, Apr and May, and a fledgling (of race *ellae*) in early Aug. Nest said to be cup-shaped. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Reported as common. Has declined; ranges of all races have contracted and become fragmented owing to extensive habitat loss from deforestation. Should probably be accorded conservation status of Near-threatened, if not Vulnerable.

Bibliography. David & Gosselin 2002a, Delacour & Mayr (1946), Dickinson *et al.* (1991), Gilliard (1950), Gonzales & Rees (1988), Goodman & Gonzales (1990), Hachisuka (1935), Inskipp *et al.* (1996), Kennedy *et al.* (2000), McGregor (1909–1910), Parkes (1973), duPont (1971), duPont & Rabor (1973b), Rand & Rabor (1960), Whitehead (1899a).

Class AVES

Order PASSERIFORMES

Suborder OSCINES

Family AEGITHINIDAE (IORAS)

- Small, arboreal insectivores with straight, rather long, notch-tipped, pale bill, and minute rictal bristles; plumage combining greens, yellows, black and white, with unusually long flank feathers silky white.
- 11·5–15·5 cm.

- Oriental Region.
- Thorny acacia savanna to deciduous and evergreen lowland forests, extending to mangroves, secondary growth, plantations and wooded gardens.
- 1 genus, 4 species, 17 taxa.
- No species threatened; none extinct since 1600.

Systematics

Linnean genera dealt with structure on a grand scale, and speculation among ornithologists of the day about the nature of the bird that the great man had named *Motacilla Tiphia* ranged from "flycatcher" or "finch" to "warbler" and, later, "babbler". Over 50 years later, in the early nineteenth century, the taxonomist L. P. Vieillot based the genus *Aegithina* on a "warbler", but one that, he believed, hailed from North America. In 1821, decades before Vieillot's key illustration was reinterpreted, T. Horsfield published the rival name *Iora*, attached to an undoubted specimen from Java. Adopted in 1840 by G. R. Gray, who thought that *Aegithina* might actually have been meant for a tit (Paridae), and grouped in the now eccentric-sounding subfamily Accentorinae of the "Sylviadae", this second name became the favoured option. Ultimately, Gray himself back-tracked, and nearly 30 years later, in 1869, erected an actual family Aegithinidae, but he filled it with babbler (Timaliidae) genera, sandwiching *Aegithina* between *Mixornis* (the modern-day *Macronous*) and *Malacopteron*.

A decade before that, E. Blyth had taken a different tack. Working at the Calcutta museum, in India, and likely to have been familiar with representatives of these avian groups in nature, he had allied the ioras with the leafbirds (*Chloropsis*, but then placed in *Phyllornis*) and the fairy-bluebirds (*Irena*) in an exclusive subfamily, Phyllorninae, of the bulbuls (Pycnonotidae). Blyth's was the scheme adopted in 1882 by R. B. Sharpe in volume six of the landmark *Catalogue of the Birds in the British Museum*, except that, by then, bulbuls, too, were being treated as babbler allies; indeed, Sharpe went to the limit by squeezing the entire group, phyllornines included, into just one subfamily of the Timaliidae. Support for this dramatic act of lumping lasted well into the new century. As it waned, H. C. Robinson re-erected a family Aegithinidae, this time exclusively for ioras and leafbirds, but he still viewed these as intermediate between bulbuls and babblers.

In 1960, J. L. Peters's *Check-list of Birds of the World* reconnected ioras and leafbirds with fairy-bluebirds in a family Irenidae, sitting next to Pycnonotidae. The reviewer, J. Delacour, may have missed A. Wetmore's osteological evidence, involving palate structure, for maintaining iora links with leafbirds alone. This was published in the same year, whereas seven years previously W. J. Beecher had used comparative anatomy of the jaw musculature to distance *Aegithina* from all of its former associates.

More recent, molecular-level taxonomic work has furnished its usual round of shock results, with support remaining for only a few of these morphology-based ideas. Pioneer experiments with DNA–DNA hybridization, published by C. G. Sibley and J. E. Ahlquist in 1990, located *Aegithina* as the sister-group of a greatly expanded bush-shrike subfamily, Malaconotinae, at the heart of these authors' oscine "parvorder" Corvida. *Chloropsis* and *Irena* they placed near the base of Corvida, indicating that they considered these two genera to be more ancient. A decade later, in the first year of the twenty-first century, the results of nuclear-DNA base-sequence comparisons by F. K. Barker and colleagues, reviewed by J. Cracraft and co-workers in 2003, provided good support for *Aegithina* as being the sister-taxon of an array of "corvidan" birds, including woodswallows (Artamidae), butcherbirds (Cracticidae) and vangas (Vangidae), but severed other links decisively by transferring *Chloropsis* and *Irena* to Sibley and Ahlquist's other parvorder, Passerida. Hypothetical links with flycatchers (Muscicapidae), warblers (Sylviidae), babblers and bulbuls, all "passeridan", had automatically already been cut and, for the first time, the ioras gained exclusive family status. They are given it herein, but are kept close to the formerly associated leafbirds and fairy-bluebirds, which is where those relying on the traditional "Wetmore sequence" would still expect to find them.

Much of the above has had to do with researching just one widespread species, the Common Iora (*Aegithina tiphia*). The other members of the family, although less well known, are superficially similar. For a part of its taxonomic history, the Southeast Asian Great Iora (*Aegithina lafresnayei*) was assigned a separate genus, *Aethorhynchus*, but it is now generally viewed as merely being larger than its cousins, with no need of any such split.

The family is safely monogeneric, but how many biological species it includes has, until recently, hung on what relationship the south Asian Marshall's Iora (*Aegithina nigrolutea*) is considered to have with the Common Iora. These confusing birds have overlapping ranges, but Marshall's Iora is well known only in north-central India, principally in the states of Gujarat, Rajasthan and Uttar Pradesh. There, it appears that the two partition living space by habitat, Marshall's selecting or being restricted to the more arid biotopes. The ecological record stops at that, and recent authors have continued to express doubt about the status of *nigrolutea* and *tiphia* as separate species, even though the standard handbook on south Asian birds, by S. Ali and S. D. Ripley,

records that, in the field in Gujarat, its senior author was able to separate them "at once" by ear.

During the breeding season in north-central India, male Marshall's Ioras sport a bright yellow collar, replicated with only slightly broader black feather fringing among co-occurring male Common Ioras of the subspecies *humei*, but reduced in more distant populations. From this observation sprang a suggestion, by H. Whistler and N. B. Kinnear, that variation in the Common Iora breeding plumage through peninsular India might involve intergradation with *nigrolutea*. Whistler was also aware that deep within *tiphia* country, remote from the "core" northern range of *nigrolutea*, occasional individuals displayed the latter's characteristic silvery or black, boldly white-edged tail. These, he reasoned, were Common Ioras exhibiting more *nigrolutea* influence than normal, and he singled out a southern Indian example from the hills of Coimbatore district, in the state of Tamil Nadu.

In 1952, D. Marien, the first modern reviser of this part of the genus, took these "variants" to be actual *A. nigrolutea*, but queried the species' breeding status away from northern India. He is presumed to have suspected non-breeding dispersal or migration by *nigrolutea* into the greater range of *tiphia*. Five years later, B. P. Hall mapped them nominally as *A. nigrolutea*, but made clear that she preferred to view them rather as exceptional products of *nigrolutea* influence on *A. tiphia*. She then formalized Whistler and Kinnear's proposal by portraying north-central Indian "*nigrolutea*" as the end point of clines of plumage coloration running north through Common Iora populations. A geographical fit of "variant" individuals into these clines was implied, with particular mention made of one post-juvenile male from Uva province, in south-east Sri Lanka, that showed a *nigrolutea*-type tail but had an upper body as dark green as that of typical local Common Ioras of the subspecies *multicolor*, at the extreme outer end of a cline in that character.

Hall's interpretation is still a widely held one, but it ceased to be the simplest available when, in 2003, D. R. Wells and colleagues shifted the focus from just tail pattern to a fuller diagnosis of Marshall's Iora versus Common Iora. This added, for the former, the characters of an absolutely smaller bill and, measured sex for sex, a shorter tail, while P. C. Rasmussen and J. C. Anderton noted the boldly white-tipped, as opposed to mainly black-tipped, tertials and inner secondaries of Marshall's Iora. With that, both of the southern "variant" specimens mentioned above shifted to the far end of the morphological spectrum, away from *tiphia*, including from series of the latter collected in the same areas. With an indication that some features may actually have diverged with distance away from north-central India, this then argued for the acceptance of these birds either as *A. nigrolutea* proper or as some related taxon yet to be named. The simpler option prevailed. From there it was a small step to accepting geographical variation in two independent species, thence to the possibility of some of that variation proceeding in parallel, which would explain the match of green colours and other characters. The upshot is a formal argument for accepting Marshall's and Common Ioras as two good species and, from the total distribution of "variants", for recognition that both may occur over most of the Indian Subcontinent, including Sri Lanka.

Barring a few small equatorial islands and tiny fringe of semi-desert, the distribution of the Common Iora alone defines the global range of the family. For good reasons, this species has long been a troublesome bird for taxonomists; indeed, some of the questions posed by the far-sighted A. O. Hume in his pioneer 1877 essay on iora systematics are still open. The currently accepted subspecies of the Common Iora are those allowed by Marien on the basis of variation of male breeding plumage, adjusted by Hall after a parallel analysis of the non-breeding, so-called "eclipse" plumage (see Morphological Aspects). Predictably, they have not been challenged, but one of the changes made raised an issue that new theoretical interest in species would not let pass. It introduced a taxon, *A. t. deignani*, defined by its describer, Hall, as grey-green on the cap and upper body of the eclipse-plumaged male and on the lower back and rump of the breeding male, this colour being intermediate between the chalky-washed lime-green of these plumage parts in the north-central Indian race *humei* and the black-dusted dark grass-green of south

Early taxonomists were at a loss regarding which family they should assign the ioras to, and they vacillated between calling them "finches", "warblers", "flycatchers" or "babblers". They were later linked with bulbuls (Pycnonotidae) and leafbirds (Chloropseidae), until recent genetic research placed them in a family of their own. While vague similarities to all the above groups are apparent, this female ***Common Iora*** *bears a stronger resemblance in structure and pattern to some members of the New World Vireonidae, and indeed these ioras and vireos, so widely separated geographically and taxonomically, probably occupy similar ecological niches. The plumage of ioras tends towards olive and yellow and all members of the group have dark wings, most of them with striking pale wingbars.*

[*Aegithina tiphia aequanimis*, Sabah, Borneo. Photo: Roland Seitre]

*While the male **Common Iora** tends to be blacker-backed than the female, this difference is not always clear-cut throughout the year, or across the geographical range of the species. In some races, such as Indian* humei, *males have black upperparts in the breeding season, but return to female-type plumage with a post-nuptial moult. Males from the Malay Peninsula, meanwhile, seem to vary individually but consistently throughout the year: the upperparts of some are only slightly darker than females, while in others, like this one, they are permanently black.*

[*Aegithina tiphia horizoptera*, Krangi Dam, Singapore. Photo: Jimmy Chew]

Indian and Sri Lankan *multicolor*. Having thus defined it in relation to these south Asian races, Hall gave *deignani* a type locality not in India, but in central Myanmar, and with this an entirely separate Myanmar distribution, remote from its Indian range between *humei* and *multicolor*.

Among sedentary birds, disjunct distributions down to subspecies level might arise from the rare, chance crossing of a barrier, or where recent extinction has broken population continuity and, for ecological reasons, left a gap. No such arguments apply in this case. Common Ioras occur continuously around the two range parts of *deignani*, and two other subspecies fill the whole space between them. Assuming that *A. tiphia*, as constituted here, is indeed a single species and that, as observed, its populations intergrade freely where they meet, creating, incidentally, notorious identification problems, most contacting populations ought also to be one another's nearest genetic neighbour. The two half-populations of *deignani* may pass as an entity morphologically, but they should be less closely related mutually than either one is to other subspecies. Given Hall's own remark that *deignani* characters are expressed more uniformly in Myanmar than in India, and the later comment, by H. Abdulali in 1981, that Indian *deignani* "is a very difficult race to separate", Wells and colleagues recently opted to restrict this taxon to the Myanmar part of its range. For the Indian part, they reinstated a broad zone of intergradation between *humei* and *multicolor*, populations within which were in the past assigned nominally to one or other of these two subspecies but are more sensibly left unaligned. In this zone, resemblance to Myanmar *deignani* proper is taken to be convergent, and similar grey-green plumage colours should be looked for in zones of contact between lighter and darker subspecies elsewhere in the Common Iora's range. Incidentally, this action nearly parallels one taken by Hall herself for dealing with a disjunct distribution left in Marien's definition of the range of the nominate race of this species, South-east Asian populations of which acquired the separate names of *A. t. philipi* and *A. t. cambodiana*.

Morphological Aspects

Ioras are small to medium-small passerines, about 11·5–15·5 cm in total length. Common and Marshall's Ioras have an adult male wing length of 60–67 mm, little different from the 61–68 mm of the Green Iora (*Aegithina viridissima*), while the wing of the slightly larger Great Iora measures 69–74 mm. All have blunt wingtips, typical of sedentary surface-gleaners. The blue-grey bill is straight, proportionately rather long and, except in the case of Marshall's Iora, slightly inflated, showing little taper along its length, with a finely notched and nailed upper mandible. Culmen length measures up to 16·5 mm in Marshall's Iora, 18·3 mm in the Green Iora, 19·5 mm in the Common Iora and 25·2 mm in the Great Iora. No species exhibits more than rudimentary development of the rictal bristles.

Despite some overlap at population level, males of all species are on average larger than females in all standard measurements except tail length. Among the smaller species, males are in fact shorter-tailed than females, absolutely so in some populations of the Common Iora, but only as adults. Juvenile males' tails are as long as those of females of all age-classes, and the new-grown first adult tail of a male Common Iora can be 5 mm to as much as 8 mm shorter than the one that it replaces. In foraging terms, when prey are taken by acrobatic reaching, the difference could carry a fitness cost. It is therefore suspected to have a special adaptive explanation. No research on this has been done, but comparison with another group having this same characteristic hints at a possibility. The three calyptomenine broadbills (Eurylaimidae) all show it strikingly, and an aspect of behaviour that at least some species of these two remotely different kinds of bird have in common is acrobatic sexual display-flying, strictly by males. Perhaps a proportionately short tail conveys some performance advantage, but this is no more than a guess. Male Marshall's and Common Ioras are well-recognized acrobatic displayers (but see Breeding). The Green Iora, with an equally reversed dimorphic tail, has not been recorded as displaying acrobatically, although

it is difficult to study in its rainforest-canopy living space, while the only described display of the Great Iora was simple by comparison, and this one member of the family shows no sexual tail dimorphism.

A second special feature, exaggerated in males of all iora species, is the soft, silky-white plumage of the upper flanks. Abundant, unusually long, and erectile together with other long dorsal feathering, this becomes a weather-guard during roosting and brooding. During ordinary flight, it is arched over the upperparts in what may be a signal display, this being the source of repeated claims that ioras have a white rump. The male's flank feathering also features in courtship displays (see Breeding).

Adult ioras of all four species show a degree of sexual dichromatism. In the case of the Green Iora, this involves most of the plumage, but in other species, basically, only wing colour and the richness of yellow on the face and underparts are affected. The colour of the central tail feathers of Marshall's Iora is black in males and silvery grey in females, and male Common Ioras of most, but not all, subspecies have black uppertail-coverts and tail, whereas these parts are green in females. In detail, apart from fine white or yellow edging on the outer webs of the flight-feathers, male wings are either wholly deep black, as those of the Great Iora, or black with a pair of bold white bars formed by the median coverts and the outer webs and tips of the secondary coverts, white extending to the sides of the tertials and inner secondaries in the Common Iora and broadly to their tips in Marshall's Iora. Females have only the flight-feathers black, and even then typically olive-washed to, in the Great Iora, never more than olive-grey. Their wingbars are narrower, and in female Green Ioras also yellow, and yellowish tips of the secondary coverts of some Great Ioras form an incipient bar. Other female coverts follow the green of the upper body, and the tail is always green.

The basic iora may otherwise be thought of as green above, from cap to tail, and, depending on species, green to greenish-yellow or yellow below, with yellow at the hidden bases of the mantle and neck feathers. Yellow on the face ranges from a narrow eye rim to a broader pattern on and around the eyelids. Tones of green vary geographically, least so in the Green Iora itself, most in the widespread Common Iora and, supposedly, Marshall's Iora. In both of the last two, they range from yellowish-green or lime-green, the extreme of which is seen in north-central India; through medium olive-green, which occurs widely in the Common Iora; to darkish grass-green, the extreme of which is found in southernmost India and Sri Lanka.

That fairly well defines juveniles and females. Across species, greens of males beyond the subadult stage vary geographically, from being more or less pure, to being washed chalky or dusted black, or a mixture of the two, as a result of fine dots at the tips of the outer barbs. Chalkiness is limited to green parts of the body plumage of Common and Marshall's Ioras in north-central India. Most of the rest of a complicated picture is due to melanin pigmentation, ranging from virtually none, through various strengths of dusting as dots expand along the barbs, to blocks of solid, slightly glossy black variably affecting the face, cap, upper body to upper-back level, and uppertail-coverts and tail. Among post-juvenile male Common and Great Ioras, this melanin deposition quite commonly switches on at the middle stage of the moult, producing parti-coloured tail feathers.

Other than in the Green Iora, some of this variation is also individual, and the appearance of Common and Marshall's Ioras, at least, is further affected by seasonal moults. The subspecies classifications of both Marien and Hall (see Systematics) succeeded only by taking the latter into account and by comparing, strictly, like stages with like. Individual variation blurs taxonomic boundaries, and it positively typifies a whole subspecies of the Common Iora, namely *horizoptera*, identified from south Myanmar and central Thailand south to Sumatra and its satellites, in which adult males vary from extensively black above to almost, but never quite, as "un-black" as females. Even more oddly, male blackness in this species is patchy on a geographical scale, with two subspecies in the Indian Subcontinent and, in South-east Asia, relatively unvarying black-capped and black-backed *deignani* and its southern neighbour *horizoptera* marooned among permanently green forms. This green "henniness" reaches an extreme in Java and Bali, where male Common Ioras of the subspecies *scapularis* fail even to acquire black uppertail-coverts and tail. Interestingly, sexual tail-length dimorphism in *scapularis* is less clear-cut than normal, making an investigation of its behavioural significance of special interest.

The biological connotation of individual male blackness versus greenness among Common and Great Ioras is unknown. In his 1877 essay, Hume speculated that enhanced blackness marked out "special vigor", but no-one has reported any social or productivity edge gained by blacker males over green ones; nor does degree of blackness seem to affect the brilliance of the golden-yellow throat and breast in breeding dress. Nowadays, vigour would be called "fitness", to be measured perhaps by survivorship, implying that blackness might develop or advance with age. Another nineteenth-century author, V. Legge, thought exactly that, on the basis that he believed Common Iora males in Sri Lanka to breed occasionally when in green plumage, but only because he had seen some around during the local nesting season. Male ioras do pass through a green subadult plumage stage, acquired by partial moult, but the question of whether blackness really does advance with age thereafter has never been answered.

Apart from permanently black or pied wings, uppertail-coverts and tail, full post-breeding moult reverts male Marshall's Ioras and male south and outer-tropical South-east Asian Common Ioras to a female-like appearance that may assist temporary relaxation of territoriality. Out of this have grown assumptions about what might be happening in the inner tropics, particularly of South-east Asia. Thus, at one extreme, there is a claim that male Common Ioras of the subspecies *horizoptera* show the same amount of seasonal change as do northern forms, and, at the other, the belief that in ever-wet equatorial environments no plumage alternation occurs at all. Neither of these conflicting ideas has been properly investigated, but neither can be wholly true. As black-morph *horizoptera* males never entirely vanish from, for example, the Malay Peninsula, the best interim guess is that supporters of the assertion that a full eclipse plumage occurs there have confused seasonal possibilities with the unique amount of permanent individual variation in this subspecies. The reverse claim implies either no differentiation of seasonal plumages or no actual prenuptial moult, yet males of *horizoptera* exhibiting a

In some races of the ***Common Iora****, notably those confined to islands, males are either relatively dull, or permanently hen-plumaged. The best example is provided by the form* scapularis *of Java and Bali, in which the males never develop black body plumage, and the sexes are virtually indistinguishable in all seasons. Reduced sexual dimorphism in island populations is a common tendency, by no means restricted to Aegithinidae, but nonetheless baffling, as are the marked geographical discrepancies in the plumage patterns and moult strategies of Common Ioras. These puzzles will perhaps best be solved by a study of upperpart colour, its seasonality, and its correlates, in different populations of males.*

[*Aegithina tiphia scapularis*, Kangassam, Bali. Photo: Tony Tilford]

Ioras spend most of their time amongst foliage, near the tips of branches, rarely feeding on the main branches themselves, and never on trunks. They are often seen peering under leaves or reaching out to pluck a prey item from a leaf or twig. Seeds or fruit may sometimes figure in the diet, but the available evidence suggests that ioras are essentially insectivores. This male ***Marshall's Iora*** *in non-breeding dress is probing acrobatically into a cluster of dead foliage at the tip of a tiny branch in the open* Acacia*-dominated woodlands of north-east India, no doubt rooting out a pupating insect of some sort. This foraging tactic is typical, but ioras also perform quick aerial sallies after flying prey.*

[*Aegithina nigrolutea*, north-east India. Photo: Göran Ekström]

conspicuously bright golden-yellow throat early in the breeding season are regular. The answer must, therefore, be that at least a bit of both occurs there, perhaps independently of individual variation. On the other hand, G. F. Mees, in 1996, found no sign at all of breeding colours in henny-plumaged Javan *scapularis*, nor could he confirm that it showed any prenuptial moult.

In sum, therefore, the greenness versus blackness, at least of the Common Iora, has no obvious connection with either climate or latitude. Perhaps colour divergence emerged randomly in formerly isolated population pockets that have since largely become reconnected.

Habitat

At family level, habitats occupied by aegithinids range from mangroves and pioneer strand woodland, including casuarina (*Casuarina equisetifolia*) stands, on accreting coastal dunes, inland across a full spectrum of broadleaf tree cover. These inland wooded areas range from stunted, arid-zone acacia (*Acacia*), mimosa (*Mimosa*) and saltbush (*Salvadora*) scrub, exclusive to Marshall's Iora, and from tree plantations, orchards and wooded parks and gardens, ultimately to deciduous woodland and the edge and canopy of semi-evergreen and fully evergreen rainforest, the latter inhabited by the Green and Great Ioras. Barring extremes of aridity and high evergreen-forest cover, the Common Iora spans the entire spectrum.

This is a lowland family, its South-east Asian forest-adapted members ranging onto submontane slopes, with the Great Iora perhaps confined to such slopes where it approaches the southern end of its range in Peninsular Malaysia, although nowhere known to reach the ecotone with montane forest. Common Ioras in the Indian Subcontinent, on the other hand, occasionally reach 2000 m or, in the eastern Himalayan foothills, slightly above this altitude. By virtue of preferred plant cover, north-central Indian populations of Marshall's Iora are plains-restricted, but this seems not to be true universally. Ways in which this species and the Common Iora interact ecologically elsewhere in the subcontinent are still undescribed.

Aegithinids are arboreal birds, living at tree-canopy level. Only exceptionally do they come to ground, and this appears as true of subdesert scrub-living populations of Marshall's Iora as it is of Green and Great Ioras in high forests of South-east Asia. In one observed incident, descent to the ground was accidental: two male Green Ioras locked in combat fell on to a forest track, where they were caught by hand.

General Habits

Regardless of habitat type, ioras rarely fly beyond the distance between neighbouring crowns. Their typical dispersion patterns, however, vary, and these do seem to be habitat-linked. In the Common and Marshall's Ioras, which are generally absent from closed-canopy forest, space is partitioned by territory-holding pairs the positions of which are advertised by loud vocalizations of the male. This is said to be relaxed in extreme seasonal parts of their ranges, including in northern India, where non-breeders join mixed-species foraging parties, and singing by both species is limited outside monsoon months. Elsewhere, the sight of more than two adults of these species in close proximity at any time is unusual, and the largest typical social unit consists of a parent and dependent offspring. The Green Iora, hardly emerging from closed, evergreen forest, is, by contrast, permanently or nearly permanently social, foraging throughout the year in parties that normally include several adults. Usually, these accompany mixed-species flocks, with some social cohesion implied by follow-my-leader flight behaviour. On the other hand, calling from within the flock is common and, just possibly, mated pairs join these gatherings independently. They are presumed to decamp in order to nest, but may still rejoin to forage, although the incident of the two males caught by hand, which returned to fighting after re-

lease (see Habitat), implied some form of territoriality, perhaps in defence of nest space.

Great Iora habitats overlap those of Green Ioras, but Great Ioras emerge more often into forest-edge vegetation, and towards the northern limit of the species' range, in north Vietnam, are described as entering groves and hedges. In Peninsular Malaysian evergreen forest this bird seems not to be social, although it occasionally joins mixed-species parties, but one such flock containing more than two adult Great Ioras is on record from neighbouring semi-evergreen forest. Otherwise, almost everything about the natural history of this bird is still rather mysterious.

The males, at least, of all iora species often spread the long, silky-white flank plumage over their lower back and rump apparently as some form of social signal during flight. These displays, better known for the Common Iora than for the other three species, range from normal-looking, horizontal flight to stiff-winged passes between two or more regular perches, and are conducted with the tail held depressed and the white of the flanks fully exposed. More certain courtship sequences, recorded for the Common and Marshall's Ioras, are described below (see Breeding).

Voice

So far as strictly vocal repertoires are concerned, most sounds made by ioras are strident, with a rasping or burring quality, and have a certain unmusical strangeness, all reasons why iora calls are so easily recognized and remembered. Above all, they are stereotyped. Despite the size of some individual repertoires, such as that of the male Common Iora, and in complete contrast to the leafbirds, with which aegithinids were formerly linked (see Systematics), iora songs ordinarily lack any cross-species mimicry. A claim by A. M. K. Bharos of a Common Iora mimicking an Ashy Drongo (*Dicrurus leucophaeus*) is the only one of its kind, although the reverse, mimicry of the iora by a drongo, is probably common.

Comparison of the repertoire ranges of the four members of the family is hampered by a shortage of information on the Great Iora. Nevertheless, it is noticeable how few loud, presumed distant advertising calls have been described for the Green Iora compared with Common or Marshall's Ioras. This difference is perhaps linked to these species' differing modes of dispersion, the Green Iora being strongly social and foraging in a group space, whereas the other two forage in more or less permanently partitioned pair spaces only (see General Habits).

The male Common Iora's courtship display from a perch (see Breeding) is preceded by a bout of long-calling. This call is a loud, monotone whistle, long drawn-out or broken into a series of short segments, with a sudden drop through approximately one octave to a further short plateau, and can be transcribed as "whee-ee-ee-ee-ee-ee-ee-ee-ee pyórr-rr-rr". Neighbouring males tend to respond to this advertisement with the same call. Interestingly, the vocal repertoire of Marshall's Iora appears to lack this long-call.

Ioras make external mechanical sounds, as well as vocal ones. The mechanical sounds of the Common Iora include a throbbing wingbeat, noticed particularly from males performing display flights. High-pitched frog-like or cricket-like sounds recorded from this species during the descent part of the "parachute" display (see Breeding) have been guessed to be mechanical, even though parachuting is also accompanied by a vocalization, which continues after the bird has landed.

Food and Feeding

"Seeds" have been reported in one or more stomachs of Common Ioras from Sarawak, in north-west Borneo, and C. W. Mason and H. Maxwell-Lefroy identified "remains of buds" in one of six stomachs from India. Furthermore, Robinson claimed that Common Ioras in the Malay Peninsula occasionally ate fruits and berries, especially those of mistletoes (Loranthaceae). No such behaviour has been corroborated in the field, however, and recent observers have assumed that the three smaller iora species, at least, are all fully insectivorous. These forage predominantly from leaves and twigs, rather than along branches; indeed, in R. A. Noske's observations in mangrove forests of the Malacca Straits, 100% of foraging attempts by Common Ioras were directed at leaves and twigs. Typically, all three forage at the outer edge of the crown, the Green Iora ascending to

*Our knowledge of the breeding behaviour of the **Green Iora** is, to say the least, incomplete. Only one confirmed nest has been reported, 8 m above ground level, and no detailed description is available. The nests of its relative, the Common Iora* (Aegithina tiphia)*, are often liberally enmeshed with cobwebs, which hold the structure together, and help to provide camouflage, especially when fragments of bark and lichen are incorporated into outer layers. On the basis of this photograph, it seems that similar nest-building behaviour extends to the Green Iora: it shows a busy female collecting a bundle of cobweb from the forest canopy.*

[*Aegithina viridissima viridissima*, Danum Valley, Borneo. Photo: Roland Seitre]

*As the **Common Iora** is such a common and familiar species over a broad geographical range, more is known about its nesting habits than for any other member of the family. It builds a neat cup-shaped structure with steep walls, anchoring it to twigs or branches using cobweb. Less often, the nest is placed directly on to the bark surface of a bough. The usual location is towards the outer tip of branches, or in saplings, most often 2–10 m above ground level. This photograph shows the contrast between the pale cobweb-felted exterior of the nest and the dark interior. Because they are adhesive, cobwebs are not used on parts of the nest which touch the incubating bird.*

[*Aegithina tiphia scapularis*, Bali.
Photo: Morten Strange]

the top of the forest canopy and regularly into the emergent crowns of giant trees.

The birds' actions on thin, pliable supports are often acrobatic. They involve much peering at the undersurface of leaves, and frequent reaching, which the proportionately long, straight bill must assist. The relatively large size of the bill, at least of the Common, Green and Great Ioras, also implies a capability of taking quite large prey, and the Common Iora is said to capture insects up to the size of, and including, large mantids. Various smaller insects, and also spiders (Araneae), feature in the diet, and those taken by the Green Iora include ones attracted to ripe fig (*Ficus*) crops in the forest canopy. Caterpillars are important to both of these species, and have also been mentioned as prominent in the diet of Marshall's Iora. Occasional flying insects, chiefly butterflies and moths (Lepidoptera), are taken in a short dash, but are always carried back to a perch to be processed.

Data on the Great Iora are lacking, but, as noted, over part of its range this species shares space with the Green Iora. The differences between these two in both bill size and total size suggest that diet and foraging behaviour may play a role in maintaining ecological distance between them.

Breeding

An undoubted courtship display of the Common Iora, given from a perch in the presence of a female, and after a bout of long-calling (see Voice), involves the male leaning forward, drooping his wings, spreading his tail and erecting the flank tufts. A second display by this species, and performed also by Marshall's Iora, is more energetic. In this, the perched male fans out the tail, tips the bill skywards and puffs out the rich yellow throat plumage, then shoots vertically upwards for a metre or more, erecting the body plumage, including that of the flanks, into a "feather ball", and executes a controlled "parachute" drop, descending directly or in a spiral to alight close to the perched female. It is possible that the spiralling descent is assisted by the spread tail. Once the male has landed, the perched display is resumed and the sequence repeated. While perched displays have been recorded widely, the parachute display, curiously, is described only from the Indian Subcontinent. Not a single report has been found from anywhere in South-east Asia, and this situation, if real, sits awkwardly with the explanation of sexual tail dimorphism mentioned above (see Morphological Aspects). Even within the ornithological literature of the Indian Subcontinent, it is difficult to judge where original description stops and copying-on begins. One radical possibility, yet to be followed up, is that the parachute display belongs to Marshall's Iora alone.

So far as the other two members of the family are concerned, the male Green Iora possesses all the expected special morphology, but its displays are unknown. The one reported instance of Great Iora display involved a puffed-up male launching itself forwards from a perch into a short, direct drop, without an initial vertical leap or a spiralling element. Evidently, all four species are in need of further, detailed attention.

In highly seasonal parts of the Indian Subcontinent, breeding by ioras is compressed into the summer wet period, principally June–July in the Indian state of Gujarat. In seasonal central Thailand, the Common Iora lays from March to June, this period in fact preceding the onset of wet weather. Its nesting seasons in less severely limiting parts of its global range are more prolonged. Thus, the Common Iora nests from December to September in southern India and Sri Lanka and during January–October in the Malay Peninsula, while in Java it breeds more or less throughout the year, although with a March–June peak of laying activity.

Three nests received by the oologist E. C. Stuart Baker, all from the West Malaysian state of Perak, constitute the sum of what has been reported of the breeding of the Great Iora. Stuart Baker described them as slightly larger than typical Common Iora nests, but accompanied by eggs that were an almost exact match for those of this significantly smaller species. He also stated that the nest trees, evidently small as all three nests were described as being situated below 2 m, had been colonized by aggressive tailor ants (*Oecophylla*), apparently without realizing

*The breeding cycle of the **Common Iora** is an egalitarian affair, and the same is probably true for all members of the family. It is possible that nest-building is the responsibility of the female alone, but both sexes contribute time to incubation, and to all other aspects of parental care. Adult males and females provision nestlings with food, brood them and shelter them from rain. Here a female is seen, first bringing a sizeable insect for her progeny, and then extracting a faecal sac for disposal away from the immediate surroundings of the nest. Clutch size in this species ranges from two to four eggs, with the lower figure being most common in tropical regions, and larger clutches being more frequent further north in the Indian Subcontinent. These photographs show a nest full to overflowing and it is difficult to imagine four chicks fitting in to such a construction. It takes an average of 14 days for the eggs to hatch, but the duration of the fledging period is unknown. For these particular chicks, the days of nest-ridden dependency are drawing to a close; judging by the advanced development of their flight-feathers, they will probably fledge within the next couple of days.*

[*Aegithina tiphia*, Karnataka, India. Above, photo: Vivek Sinha/ Oxford Scientific Films.

Below, photo: Vivek Sinha/ VIREO]

Forest clearance has been a benefit to half of the Aegithinidae family, and a bane to the other. The Common (Aegithina tiphia) *and Marshall's Ioras* (A. nigrolutea) *are species of relatively open habitats, and can thrive in scrubland, young regrowth and even in suburbia. Deforestation is their benefactor. The* ***Green Iora****, however, is restricted to tall lowland forest, adjacent mature secondary growth and relatively intact shade trees left standing over orchards and plantations, habitats whose extent has declined dramatically in the Sundaic region over recent decades. This species remains common on lower slopes and in fragments of native forest, but overall numbers must have plummeted. As with all forest birds in tropical Asia, a greater area of habitat needs to be brought under protection.*

[*Aegithina viridissima*, Panti forest, Johor, Malaysia.
Photo: Ong Kiem Sian]

that this fact would have placed the sites outside forest and taken them into the exclusive habitat of the Common Iora. In short, Stuart Baker is likely to have been misled, and the real nest of the Great Iora remains to be discovered.

Smaller iora species all build neat, steep-walled, open cup-nests, heavily felted externally, and anchored to twig and branch forks, or directly on to the bark surface of a bough, with cob-web silk. The latter's greyish colour camouflages the structure, making the nests hard to spot against the wood substrate, and some Common Ioras complete the disguise by incorporating bark fragments. The nests of Common and Marshall's Ioras are comparatively well known, whereas details of the Green Iora's nest again depend on material sent to Stuart Baker, backed by a few more recent, distant views. In its scrub habitat, Marshall's Iora often builds its nests as low as one metre from the ground, while most Common Iora nests are much higher up, to 10 m. A height above ground of 8 m is the only such statistic obtained for a Green Iora nest, and it is not yet known if this aegithinid is among those canopy-living bird species that, for breeding purposes, transfer to the more equable micro-climate of the shade layers of the forest.

The only aegithinid eggs that have been described reliably are those of the Common and Marshall's Ioras. These are variably broad to longish ovate in shape, with slight to no gloss. The ground colour is pale cream to grey-tinged or, sometimes, pinkish in the case of the Common Iora, and white to pinkish in Marshall's Iora. The eggs of both are streaked purplish-grey and light brown to reddish-brown over, or in a zone around, the broad end, but not more than stippled elsewhere; and some eggs of Marshall's Iora have only the stippling. A sample of 60 eggs of the Common Iora had dimensions of 16·2–19 × 13·2–15 mm, and 20 of Marshall's Iora measured 17–18 × 12·6–13·5 mm. Two reputed Malaysian eggs of a Green Iora clutch, dated 25th May, measured 18 × 14 mm and 17·6 × 13·8 mm, respectively, hence no different in size from those of the Common Iora.

The clutch size of the Common Iora ranges from two eggs in inner-tropical South-east Asia to two to four in Myanmar, and two or, more often, three and occasionally four in the Indian Subcontinent. In north-central India, Marshall's Iora likewise lays two or three eggs, but occasionally lays four. Pair-members share incubation duties, and the incubation period of the Common Iora lasts for an average of 14 days. There is no exact information available on the duration of the fledging period of either this or Marshall's Iora, but both parents, of both species, tend the nestlings and fledglings, sheltering and brooding them by erecting the long body plumage into a fluffy ball. The observation in a Malaysian garden of a fledgling Common Iora being tended constantly by one particular parent hints at a partitioning of parental responsibilities, but more observations are needed in order to confirm this.

Apart from the single two-egg clutch referred to above, all that is known about the breeding biology of the Green Iora is that both pair-members tend the nestlings, and both brood during rain, fluffing themselves out into a ball in the manner of other iora species.

The Common Iora is a major brood host of the Banded Bay Cuckoo (*Cacomantis sonneratii*). The global ranges of the two are more or less coterminous, but the cuckoo's habitat range is broader, taking in evergreen forest. Possible alternative hosts in South-east Asian forests are thought to include the Green Iora, but this has yet to be confirmed. A Green Iora pair was also seen to chase away an Asian Drongo-cuckoo (*Surniculus lugubris*), but reaction to *Cacomantis*-sized cuckoos may be generic, and aggressive behaviour alone is no confirmation of an actual host-parasite relationship.

Movements

Only at the extreme western, semi-desert fringe of the family's range, on the Kathiawar Peninsula, in west India, has any im-

pression been gained of ioras being other than sedentary. In a highly seasonal environment there, R. S. Dharmakumarsinhji suggested that Marshall's Iora and at least some Common Ioras behaved as migrants, perhaps on a local scale, the latter arriving in April and May, breeding during the rains of the south-west monsoon, and then departing in October. About a decade earlier, however, Ali, working in a part of the same area, had treated Marshall's Iora as a resident and made no mention of the Common Iora as occurring there at all. No later reference covering this region has even raised the issue of migration. From that it is inferred that silent individuals in eclipse plumages (see Morphological Aspects) may have been overlooked.

Relationship with Man

Whereas the Green and Great Ioras are largely confined to forest habitats, the other two members of the family enter orchards and fruit groves from time to time. Indeed, one of the Tamil names for the Common Iora means "little mango bird". Neither of these latter two species is, however, in any way a pest and, even though they may take some injurious insects, they make no obvious mark on crops one way or the other. Man's relationship with these birds, apart from having an impact on their ecology and conservation, is purely aesthetic.

Breeding-season males of Common and Marshall's Ioras are brightly plumaged birds the loud, stereotyped songs and other calls of which are, to many people, redolent of generally familiar surroundings. Writing of the Common Iora in the hot plains of central Myanmar, E. Stresemann and G. Heinrich recalled its strange sounds: "he who hears this monotonous call from bush and tree along the long, dry, blazing roads, will never forget it all his life and it will remain in his memory forever associated with these arid spaces". Wherever this bird occurs, the effect on those attuned to wild sounds is the same; indeed, names for Common and Marshall's Ioras in several languages of the subcontinent are more or less onomatopoeic of calls that the two have in common. With a small stretch of the imagination this could even be true of the word "iora" itself, and also of the Indonesian *cipoh* (pronounced as "chipoh"), shorthand for the Common Iora's long-call with abrupt pitch drop (see Voice).

On the other hand, nowhere in the range of the family does there seem to be a tradition of keeping ioras as cagebirds, and not a single reference to ioras in captivity emerged in a search of over 20 years' worth of the main western avicultural literature. Perhaps aegithinids are too difficult to maintain, as wild birds living close to people are often unusually nervous; or maybe their songs are too monotonous or melancholy. Suffice it to point out that over a three-year period in the late 1960s, during a weekly survey of one of the larger public wildlife markets of the region, the Bangkok city "Sunday Market", H. E. McClure and S. Chaiyaphun found only 43 individual ioras, all Common Ioras, as opposed to some 4000 other "aegithinids", which in those days were taken to include leafbirds and fairy-bluebirds (see Systematics). Whatever it is that has kept the Common Iora out of cages is perhaps a reason why this species is still common in such close proximity to people.

Status and Conservation

Where suitable habitat remains, Common and Green Ioras tend to be fairly numerous. The vernacular name has been applied just to the former perhaps because of its larger range but, more likely, simply because of this bird's familiarity around human habitation, where it uses vegetation strictly marginal to other species' needs. In the 1940s, Ali found Marshall's Iora to be "common and generally distributed" in the Kachchh district of Gujarat, on the western side of this species' "core" north-central Indian range. Degradation of the woody cover of this arid region over time is bound to have had some impact, but none of the more recent literature suggests that any fundamental change of status has occurred in this area. Outside its core range, this iora is known from just a handful of records, but these are not an acceptable measure of true rarity as, away from this zone of expected occurrence, the bird would not have been looked for and is strongly likely to have been passed over. A more objective picture should emerge as observers realize the geographical possibilities and learn to separate the songs of Marshall's and Common Ioras as a matter of course. To this end, the recent publication by Rasmussen and Anderton, in 2005, should be of great assistance.

Of the four members of the family, only the Great Iora has rather widely been described as uncommon to actually rare, as, for instance, by A. David-Beaulieu in 1944 and B. E. Smythies in 1953. Some of this assessment, however, may have to do with the species' preferred high-canopy foraging habitat, as well as to poor knowledge of its vocalizations. In 1991, B. Lekagul and P. D. Round described the Great Iora as common in Thailand, and the present author found it so in logged but recovering semi-evergreen forest on the Thailand-Malaysia border. The latter observations included two or more individuals, with some Green Ioras, in a mixed-species foraging party, but farther south in Peninsular Malaysia, in mature submontane evergreen forest, McClure identified the Great Iora in less than 10% of the canopy-level flocks that he censused in the 1960s.

Progressive clearance of woodland for agriculture and fuel in the Indian Subcontinent cannot have failed to have an impact on the numbers of Common and Marshall's Ioras, but nowhere has it been suggested that any part of their regional distribution is under real threat. Where climax vegetation inland shifts to closed-canopy forest, as indicated, human activity is likely to have benefited Common Ioras, and on a large scale; indeed, it may even have promoted some secondary contacts. Except where their living space has been exposed to excessive fogging with insecticides, of which malathion and other such organophosphorus compounds are favourites, the Common Iora does well even in suburbia, and is a familiar sight in, for example, the planted parklands of Singapore city.

What seems to have benefited the Common Iora has had the opposite impact on the Green and Great Ioras, and will continue to do so. Both of these species are more or less tied to semi-evergreen or fully evergreen forests of South-east Asia, inland of mangroves, below the ecotone with montane forest, and mostly to mature or fairly well-regenerated growth. Over the twentieth century, and with great acceleration in recent decades, a huge part of their original living space was lost to total clearance. At least within the Sunda region, both species make use of submontane slopes, which is where most or all relict lowland forest will remain in the future. Over its main continental range north of the Malaysian forest zone, however, the core habitat of the Great Iora is suspected to have been plains-level or bottomland forest; this is now a rare habitat, excessively fragmented, and over long distances vanished, including in the aforementioned area on the Thailand-Malaysia border. The Great Iora is representative of hundreds of forest bird species through South-east Asia of which current numbers and total spread are no measure even of medium-term security. The latest BirdLife International Red Data Book on Asian birds, edited by N. J. Collar and colleagues and published in 2001, excludes aegithinids from any of its threatened categories; yet, for the Great Iora and probably the Green Iora, a 10% chance of extinction within the next 100 years, which is one of the IUCN's descriptors of Vulnerable status, seems quite a modest prediction. In *Threatened Birds of the World*, published one year earlier, the Green Iora was given the global conservation status of Near-threatened, whereas the Great Iora, somewhat surprisingly perhaps, was not listed at all.

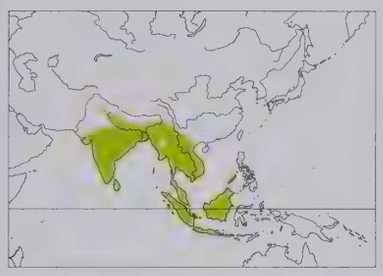
PLATE 29

inches 3
cm 8

Genus *AEGITHINA* Vieillot, 1816



1. Common Iora

Aegithina tiphia

French: Petit Iora **German**: Schwarzflügeliora **Spanish**: Iora Común
Other common names: Indian Iora, Black-winged/Small Iora; Ceylon Iora (*multicolor*)

Taxonomy. *Motacilla Tiphia* Linnaeus, 1758, vicinity of Calcutta, West Bengal, India.
Has often been treated as conspecific with *A. nigrolutea*, but differs in e.g. details of morphology, plumage and vocalizations. Delineation of races complicated by individual variation in amount of black on cap and upper body of males, intercalation of a male eclipse plumage of varying distinctness from breeding dress, some broad geographical intergradation zones (especially in Indian Subcontinent), and inter-population convergence (including of colour tones of eclipse plumages). Proposed races *singapurensis* and *micromelaena* of Malay Peninsula and islands absorbed within range of variation of *horizoptera*; races *trudiae* (from Brunei Bay, in N Borneo) and *djunkulanensis* (extreme W Java) treated as local intergrades between larger neighbouring entities. Eleven subspecies recognized.

Subspecies and Distribution.
A. t. septentrionalis Koelz, 1939 – foot of NW Himalayas in N India (Punjab, Himachal Pradesh).
A. t. tiphia (Linnaeus, 1758) – foot of Himalayas from N India (E from Punjab) E to Bangladesh, and adjacent W Myanmar.
A. t. humei Stuart Baker, 1922 – C Indian Subcontinent (E from Rajasthan).
A. t. multicolor (J. F. Gmelin, 1789) – extreme S India and Sri Lanka.
A. t. philipi Oustalet, 1885 – SC China (Yunnan), E Myanmar, N & C Thailand and N & C Indochina.
A. t. deignani B. P. Hall, 1957 – Myanmar (except W, E & S).
A. t. horizoptera Oberholser, 1912 – S Myanmar and C Thailand S to Malay Peninsula, and Sumatra and satellites (Nias I, Riau and Lingga Archipelagos, Bangka).
A. t. cambodiana B. P. Hall, 1957 – SE Thailand and S Indochina.
A. t. aequanimis Bangs, 1922 – W Philippines (Palawan) and N Borneo (Sabah), and satellite islands.
A. t. viridis (Bonaparte, 1850) – Borneo (except N).
A. t. scapularis (Horsfield, 1821) – Java and Bali.
Descriptive notes. 12·5–13·5 cm; male 13–17 g, female 12–15 g (*humei*). Male nominate race breeding plumage (acquired by partial spring moult) has upperparts mostly green, crown green with some black dusting, forehead, lores, face and underparts yellow (richest on throat and breast); uppertail-coverts and tail black; wings black, median upperwing-coverts and tips of greater coverts white (forming two conspicuous bars), sides of tertials and inner secondaries white; iris whitish; bill light grey-blue with blackish culmen ridge; feet slaty grey. Differs from very similar *A. nigrolutea*

mainly in having no white in tail, less white in wings. Male post-breeding eclipse plumage resembles female, but wings, uppertail-coverts and tail remain black. Female is duller, with green to no more than black-dusted green uppertail-coverts and tail, underparts often green-washed and without rich golden tone on throat. Juvenile and subadult are like female. Races vary mainly in tone of greens, development of yellow collar, and extent of black on male upperparts (following details refer to breeding-plumaged males unless otherwise specified): *septentrionalis* is like nominate, but slightly larger, upperparts slightly paler green, bill longer and deeper; *humei* has black cap and mantle, variable black-fringed bright yellow hindcollar (confluent with yellow of underparts), chalky-washed lime-green lower back and rump, eclipse plumage female-like with upperparts the same lime-green; *multicolor* is like previous, but no yellow hindcollar, black on body usually more extensive, rump (only) much darker, more grass-green, white bar on greater wing-coverts sometimes missing; *deignani* has black cap and mantle, usually only trace of yellow hindcollar, and lower back and rump grey-green; *philipi* resembles nominate but upperparts darker green, sometimes with black flecks; *cambodiana* differs from last in having little or no yellow on forehead and lores, green upperpart still darker, blacker-washed, cap occasionally solidly black; *horizoptera* is mainly yellow-tinged green above, black confined mostly to rear cap (variable, sometimes extending to whole cap and mantle), extent of seasonal differentiation uncertain but eclipse plumage at least lacks golden colour of throat and breast; *aequanimis* is black-washed yellowish-green above, forehead and lores pure yellow; *viridis* is like previous but smaller, lacks yellow on forehead; *scapularis* is clear yellowish-green above, including uppertail-coverts and tail, lacks golden wash on throat and breast, shows no seasonal change. VOICE. Female repertoire poorly documented. Territorial males noisy, vocally interactive, with range of strident, unmusical rasping, whistling and whining songs, loud but often rather melancholy, including: with glissading component, "di-di-dweeo" or "piyou" or "peeou", or "weet-we-to", in bouts; repeated "dweeo dweeo dweeo", or "tyior tréé-tyiór" (rendered as "oh, here we are"); couplets, "di-wee di-wee" or "dee-du wee-du"; coarse "r'yeek r'yeek r'yeek", then a pause, then mellower "pleeu pleeu pleeu"; "whip-wéé-bird-éé" or similar but trisyllabic "if you-PLEASE", about once per second, with frequently intercalated "please-me?"; long, slow bouts of "my…dáddy"; querulous "chee-wheee che-wheee che-wheee"; also "chee-chit-chit-chit-chit-chit" like that of tailorbird (*Orthotomus*), and sharp chirp while following a female. Described from most parts of range is a loud, long-drawn-out, monotone whistle and sudden drop through approximately one octave to a further short plateau, "whee-ee-ee-ee-ee-ee-ee-ee-ee pyórr-rr-rr", or the whistle is broken into a string of short segments; neighbouring males tend to respond to this advertisement with the same call. Parachuting display-flight said to be accompanied by shrill "pwee-pwee-pwee-pwee-pwee-pwee", reminiscent of a common call of Large Woodshrike (*Tephrodornis gularis*). Race *humei* said to have sweeter-toned songs than nominate, but confusion with songs of potentially co-occurring *A. nigrolutea* cannot be discounted.

Habitat. Mangroves are about the only natural closed-canopy evergreen forest inhabited permanently. Otherwise, found in pioneer coastal scrub and strand woodland, including casuarina (*Casuarina*) stands, also forest edge and light and broken woodland inland, and groves, bamboo thickets, orchards, plantations and scattered tall tree cover in agricultural and other disturbed sites; extends to rural settlements and wooded parks and gardens of suburbia, thus in regular association with humans. Said to prefer deciduous to evergreen vegetation in Indian Subcontinent, and to be commoner in drier zones in Sri Lanka. Lowlands over most of range, but in typical habitats in Indian Subcontinent occasionally to above 2000 m; in SE Asia, unrecorded above c. 800 m, i.e. well short of ecotone with regional montane habitat.

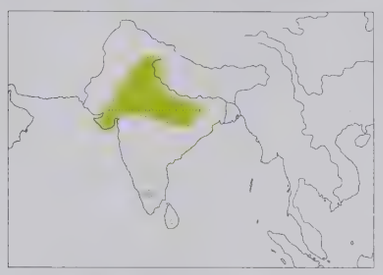
Food and Feeding. Insects and other arthropods; rumoured to take small fruits, but this unconfirmed. Prey items range up to size of large mantids; otherwise include spiders (Araneae), ants (Hymenoptera), beetles (Coleoptera), caterpillars and occasional adult lepidopterans. Loners and, commonly, pairs forage among twigs and foliage at crown level, preferring taller trees, moving often acrobatically to peer beneath leaves; occasionally, birds also dart out to snatch closely passing flying prey. In strongly seasonal environments, non-breeders frequently join mixed-species foraging parties at forest edge; occasionally with other iora species in such parties. Otherwise, groups of more than two individuals foraging together exceptional (and slight evidence from Malaysia that, for rearing purposes, fledged broods are split between parents).

Breeding. Season Dec/Jan–Sept in Indian Subcontinent, but more tightly constrained to monsoon rain (to which said to react fast) in more strongly seasonal areas; egg-laying Mar–Jun in C Thailand and Jan to early Oct in Malay Peninsula; apparently breeds in all months, but peak during Mar–Jun, in Java. Nest 1–10 m up (rarely below 2 m) in branch fork or directly on bark surface of a bough, a thick-walled, steep-sided open cup, neatly built from tree cotton, fine grass, tendrils, fibre, etc., lined with fine fibre, comprehensively felted with cobweb (locally, felting incorporates bark fragments) and also anchored to support with cobweb, so that most are difficult to distinguish from a greyish, lichen-covered woody knob; wide range of trees used, but race *humei* said to favour *Mangifera*, *Zizyphus*, *Citrus* and *Bauhinia*, also thorny acacias (including *Acacia senegal* and *A. leucophloea*). Clutch 2 eggs generally, in Indian Subcontinent often 3 (exceptionally, 4), those at least of small clutches laid up to 48 hours apart; incubation from first egg, by both sexes, only female at night, male taking slightly larger share of daytime duties, incubation period 14 days; reports of breeding male singing close to an active nest and, remarkably, while sitting on it; no reliable information on fledging period; both parents tend nestlings and fledglings. An important brood host of Banded Bay Cuckoo (*Cacomantis sonneratii*) in most of range.

Movements. Resident. Apparently local seasonal movements have been alleged to occur in W India (Kathiawar Peninsula, in Gujarat), but other observers failed to detect this behaviour there, and no such movements reported anywhere else. Said to overwinter to upper altitudinal limit of its range in Himalayan foothills.

Status and Conservation. Not globally threatened. Common more or less throughout range. Thrives even in suburbia; is a familiar sight in e.g. the planted parklands of Singapore city. No more than local threats from habitat loss or, in suburban sites, damage to food resources from pesticides. Occurs in many national parks and other protected areas through much of range.

Bibliography. Abdulali (1981), Ali (1969, 1996), Ali & Ripley (1996), Bharos (1998), Deignan (1945), Dharmakumarsinhji (1954), Dickinson *et al.* (1991), Étchécopar & Hüe (1983), Eve & Guigue (1996), Fleming *et al.* (1984), Glenister (1971), Grewal *et al.* (2002), Grimmett & Inskipp (2003), Grimmett *et al.* (1998, 2000), Hall (1957), Harrison (1999), Henry (1998a), Herbert (1923–1926), Inskipp *et al.* (1999), Jeyarajasingam & Pearson (1999), Khacher (1997), Lamsfuss (1998), Legge (1983), MacKinnon & Phillipps (1993, 2000), Madoc (1976), Mahabal & Lamba (1987), Majumdar *et al.* (1992), Marien (1952), van Marle & Voous (1988), Mason & Lefroy (1912), McClure (1998), Medway & Wells (1976), Mees (1996), Meyer de Schauensee & Ripley (1940), Mukherjee (1995), Nash & Nash (1988), Noske (1995), Phillips (1978), Rasmussen & Anderton (2005), Riley (1938), Ripley (1982), Saha & Dasgupta (1992), Smith (1943), Smythies (1986, 1999), Spennemann (1934), Spittle (1952), Stepanyan (1995), Strange (2002), Stresemann & Heinrich (1939), Stuart Baker (1922–1930, 1932), Thompson (1966), Tooth (1901a), Watt (1925), Wells (2005), Wesley (1984), Whistler (1944, 1949), Whistler & Kinnear (1932).



2. Marshall's Iora

Aegithina nigrolutea

French: Iora à queue blanche **German**: Schwarzkappeniora **Spanish**: Iora Coliblanca
Other common names: White-tailed Iora

Taxonomy. *Iora nigrolutea* G. F. L. Marshall, 1876, Meerut, north-west Uttar Pradesh, India.
Has often been treated as conspecific with *A. tiphia*, but differs in details of morphology, plumage and vocalizations, amongst others. Birds from NW India (Gujarat) described as race *sulphurea*, but now considered indistinguishable from adjacent populations. Elsewhere in range, some of the size and tonal variation apparent may eventually be recognized taxonomically. Currently treated as monotypic.

Distribution. India, in N from Himachal Pradesh S to Gujarat (S to Kathiawar Peninsula), Uttar Pradesh and N Madhya Pradesh, E sporadically (or overlooked) as far as Bihar and Orissa, and in S in NC Tamil Nadu; also Sri Lanka.

Descriptive notes. 12–12·8 cm; male 11–14 g, female 10–14 g (N India); on present evidence, smaller in S India and Sri Lanka. Male breeding plumage (acquired by partial spring moult) described only from N India: face, underparts and broad collar rich yellow, collar with small amount of black fringing; cap and upper body except rump solidly black, rump chalky green; tail black with bold white tipping, lateral feathers white along web margins; wings black, median upperwing-coverts and tips of greater coverts white (forming two conspicuous bars), tertials and inner secondaries broadly edged white, tertials also broadly tipped white (white tips wear off); iris brown; bill light grey-blue with blackish culmen ridge; feet slaty grey. Differs from very similar *A. tiphia* mainly in having white in tail, more white in wings. Male post-breeding eclipse plumage (in N India) resembles female, but wings and tail black, some black smudging on nape. Female is entirely chalky-washed green above (tone apparently darkening from N to S), tail centre silvery grey, black on wings restricted, underparts paler, more greenish-yellow, than male. Juvenile resembles female; adult tail colours assumed at post-juvenile moult. VOICE. In NW India (Kachchh district of Gujarat), song coincides with SW monsoon rainy season, and uncommon before Jun; comprises many upslurred or downslurred notes, includes "tchoo-tchoo" disyllable followed by loud, metallic "chee-tchoo-tchoo-tchee" or "chee-chó-chi-choo". Calls are of 2–4 syllables, rendered as "wheeti wheeti" or "twsee-ku-kee" or "tswee-twsee-tee-dik", also rarer variations as "ee-teh-wee-hu" and "chef-worrilee", or accelerating "jéez-whéez-zee-zee…" ("jeez" note single or doubled) like that of a tit (Paridae). Lacks long-call with octave drop of male *A. tiphia*.

Habitat. Exclusively at plains level in N of range, where favours thorny acacia (*Acacia*) jungle, and scrubby groves and gulleys; around Delhi, reported also as frequenting canopy of *Dalbergia sissoo* (sheesham) woodland. Habitat in S insufficiently described, but includes open, park-like woodland at up to 700 m.

Food and Feeding. Diet arthropods, including insect imagines and larvae. Hunts alone or in pairs, but joins mixed foraging parties after breeding season. Forages among outer twigs and crown foliage, often acrobatically to assist leaf-scanning.

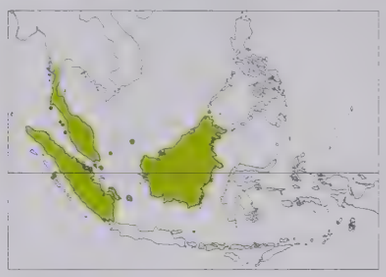
Breeding. Data only from NW India (Gujarat). Lays mainly in Jun and Jul. Nest, built by both pair-members, a small, very neat cup made of fibre and grass, lined sparsely with hair, felted externally with cobweb, placed in fork of *Salvadora* bush or directly on to bark surface of mimosa (*Mimosa*) or fig (*Ficus*) bough, often less than 3 m and down to 1 m from ground. Clutch 2–3 eggs, exceptionally 4; incubation by both sexes, and both also tend young, including either swallowing faecal sacs or dropping them at a distance from nest; no information on incubation and fledging periods.

Movements. Resident. Said to move seasonally in parts of NW India (Gujarat), but facts not established and described by others as present throughout year in that area.

Status and Conservation. Not globally threatened. Locally common in N India; status elsewhere uncertain, but probably more common than suggested by records. In 1940s, was reported as common and widely distributed in Kachchh district of Gujarat, on W side of its "core" range; degradation of woody cover of this arid region presumed to have had some impact, but no evidence that any fundamental change of status has occurred in that area. Outside core range, known from just a handful of records, but thought strongly likely to have been passed over as *A. tiphia*. Occurs in Keoladeo Ghana National Park, in N India (E Rajasthan).

Bibliography. Ali (1945, 1996), Ali & Ripley (1996), Dharmakumarsinhji (1954), Grewal *et al.* (2002), Grimmett & Inskipp (2003), Grimmett *et al.* (1998), Hall (1957), Hume (1877a), Hutson (1954), Inskipp *et al.* (1996), Kazmierczak (2000), Lester (1897), Marien (1952), Mukherjee (1995), Rasmussen & Anderton (2005), Ripley (1982), Stuart Baker (1932), Whistler (1949), Whistler & Kinnear (1932).

3. Green Iora



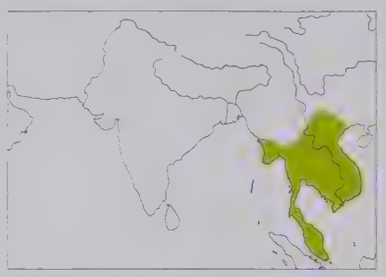
Aegithina viridissima

French: Iora émeraude **German**: Smaragdiora **Spanish**: Iora Verde

Taxonomy. *Iora viridissima* Bonaparte, 1850, Sumatra.
Population of Batu Is (off W Sumatra) named as race *nesiotis*, but considered inseparable from nominate. Taxonomic status of N Natuna Is (S China Sea) population yet to be resolved; currently included in nominate, but further study needed. Two subspecies recognized.

On following page: 4. Great Iora (*Aegithina lafresnayei*).

Subspecies and Distribution.
A. v. viridissima (Bonaparte, 1850) – extreme S Myanmar (S Tenasserim) and SW Thailand S to Malay Peninsula, Sumatra and satellites, N Natuna Is and Borneo.
A. v. thapsina Oberholser, 1917 – Siantan I (possibly also other islands), in Anamba Group (E of Peninsular Malaysia).



Descriptive notes. 11·5–12·8 cm; one immature 13·8 g. Male is mostly dark olive-green, lightening to pale yellow at rear edge of rump, clear yellow on carpus edge and central belly to undertail-coverts, whitish on rear flanks, "thigh" feathers green-tipped black; anterior face black, upper and lower eyelids broadly and contrastingly bright yellow; wings black, tips of median coverts and tips of outer webs of greater coverts white (forming two bars); uppertail-coverts and tail black; iris dark brown to red-brown; bill pale grey-blue with blackish culmen ridge; feet slaty-grey. Female has lores and full eyering yellow, rest of face and upperparts uniform medium olive-green, uppertail-coverts and tail green, wings as male but black parts washed dark olive, lesser coverts green, wingbars yellow; underparts paler-toned than above, yellowing from centre of belly, thighs yellow. Juvenile is like female; some males have parti-coloured tail, implying existence of a subadult plumage. Race *thapsina* differs from nominate principally in more generally yellowish underparts of female. Voice. Song a high-pitched, lisping "itsu-tsi-tu tsi-tu", or (described in Borneo) an even-pitched staccato sequence with upslurred first note, "wi-it dit-dit-dit-dee-dee". Commonest loud call a whining, nasal disyllable with marked tonal step, "ji-sheur" or "ji-wier"; courting male gave higher-pitched "ji-jirijiri-jeh". Repertoire limited in comparison with *A. tiphia* and *A. nigrolutea*.
Habitat. Canopy, including giant emergent crowns, of lowland evergreen rainforest, also of its peatswamp-forest and white-sand pole-forest variants; locally, also tall secondary forest and overgrown tree plantations of rubber and *Albizzia*, also *Trema orientalis* shade over cocoa. Ranges into mangrove forest on Langkawi I, off NW Peninsular Malaysia. At plains level and on submontane slopes, to upper limit of c. 820 m.
Food and Feeding. Invertebrates, including record of large caterpillar eaten; fledged young were fed on caterpillars. Food items taken from foliage and inflorescences; also attracted to insects gathered at canopy-level crops of figs (*Ficus*). Regular foraging units are a pair or a small party. Groups routinely join mixed-species foraging flocks of canopy insectivores; in Selangor (Peninsular Malaysia), was the second most frequent participating species among flocks surveyed in submontane Gombak Valley, with mean rate of 2·8 individuals per flock attended.
